At this point, you are probably thinking that it sounds too easy and that there must be a catch. The catch is that the system is not perfect; there are some pointing errors, the magnitude of which depends on the orbit involved, the position of the satellite along the orbit, whether it is a descending or ascending pass, and if the automatic tracking unit is used. To find out just how big the errors are, I made an analysis of several typical orbits.

I selected orbits for OSCAR 8 when it reached a maximum elevation of 30 degrees and 60 degrees to the east and to the west. I also analyzed the overhead pass. I drew up charts for the first four orbits—shown in Fig. 1. (There is no chart for the overhead orbit as the antenna follows the satellite very closely and the pointing error probably does not exceed 5 degrees.) The charts are set up using conventional azimuth and elevation bearings for the two axes, azimuth along the bottom and elevation up the side. You will notice that the antenna coordinates start at 170 degrees and end at 350 degrees as opposed to a true north-south. This 10-degree difference is to compensate for the inclination of OSCAR 8's orbit and will be discussed later. The antenna coordinates have been calculated, while those for the satellites have been measured using an OSCARLOCATOR. If you use the automatic control unit, the pointing errors will generally be greater than indicated by the charts since the additional dimension of time is added. With the automatic control unit, the antenna will match the satellite at the beginning, end, and midpoint of the pass. The remainder of the time there will be some additional error. This error is greatest for overhead passes and becomes minor for passes below a maximum elevation of 60 degrees.

Mounting

The way you mount the rotators will determine the degree of success of your installation, so exercise care and do the job correctly. The angles and various motions are unusual, and if you do not think things through carefully you can get into trouble.

The most important point to keep in mind is that the system must be made so that it cannot self-destruct. In this regard, my prototype was somewhat short of being a resounding success. I was trying out the automatic control unit when I noticed that the swr seemed to be increasing on the 2-meter uplink antenna. I shut everything down and headed outside to see if I could spot a loose cable or whatever. "Whatever" turned out to be a mangled ten-element "Twist" antenna. I had gotten the control unit hooked up the wrong way and automatically rotated my antenna into the chimney on which everything is mounted. Those little TV rotators are amazingly powerful. I rebuilt everything and modified the mounting so that there is plenty of clearance for the antenna regardless of which rotator I operate in any direction. Once the rotators are set up and the antennas mounted, I suggest you move the rotator controls to a position where the antennas may be observed and try simulating several satellite passes to get the feel of everything.

The mounting I ended up with has worked well for some time now, and it was very inexpensive. I will describe it in detail so that it may be copied. The dimensions and materials are not critical and may be changed to suit your situation and junk box. I constructed the mounting first, which clamps to my chimney, but you could use any type of support such as a tower or telephone pole. Next, I built the "tilt-axis" support, a rectangular arrangement of two-by-fours used to hold the tilt-axis rotator and axle.

The axle must be long enough to allow the antenna to clear the mounting support. It is mounted parallel to the Earth on a true bearing of 350 degrees. I used a piece of 2-1/2-inch aluminum conduit for the axle and a prop-pitch motor for the tilt-axis rotator. (The motor was contributed by a friend, W1NDO/3.) Smaller tubing would work just as well, and the rotator could be eliminated. If you have access to the mounting before each satellite orbit, you could substitute a brake mechanism for the rotator. Remember that the tilt-axis rotator is not operated during any particular orbit.

I started out climbing up on the roof of my house be-

fore each pass and presetting the tilt angle. This was a little inconvenient, so I added the tilt rotator. If you do use a rotator for this function, I recommend a good one, preferably one with a brake. There will be a fair amount of stress unless you keep everything perfectly balanced.

The elevation-rotator mounting board is assembled next. I used a two-by-eight board which is secured to the tilt axle with U-bolts. This board acts as a mounting platform for the TV-type elevation rotator and holds a side-thrust bearing. This bearing is nothing more than a two-foot section of pipe which is just large enough to allow the elevation mast to pass through it without binding. I used a 1-1/4-inch mast and a pipe with a 1-3/8-inch inside diameter for the side-thrust bearing. The bearing is secured to the mounting board with two U-bolts. Be sure it is perpendicular to the tilt axle or additional tracking errors will result.

Next, insert the mast in the side-thrust bearing and attach the rotator to the mast. Bolt a short section of pipe to the bracket which is used to mount the rotator. This pipe should be parallel to the side-thrust bearing and about 3 inches away. It is fastened to the rotator mounting board with two U-bolts. The rotator should be on the opposite side of the tilt axle from the antenna to help balance the tilt axis. Be sure the rotator is not mounted upside down, as then it will turn the wrong direction. You may have to file off a small tab on some TV rotators.

Paint all wooden parts and apply a little axle grease to the bearing surfaces. The rotator assembly is ready to be mounted to your supporting structure. Since the antenna rotator assembly is fairly heavy and is not well balanced, make this attachment strong. The unbalance results from mounting the assembly near the tilt rotator so that the antenna will clear the support. You should be able to point the antenna at the support with the elevation rotator and then turn the tilt rotator through 360 degrees without the antenna being fouled anywhere. The mounting should be aligned 10 degrees west of true north. This works well for OSCAR 8.

Automatic Control Unit

The purpose of the control unit is to periodically turn the elevation rotator on and off. If the frequency and duration of the "on" pulses are just right, the antenna will move evenly across the sky from horizon to horizon in the same time it takes the satellite to make its pass. Fig. 3 is a schematic of the circuit I used to operate the elevation rotator. The values of the components will turn the rotator on every 40 seconds for a duration of 1 to 3 seconds, meaning that the rotator would be on for about 2 seconds and off for 38 seconds, then back on again. At a normal rotator speed of 1 rpm (3 degrees per second), it will take 20 minutes for the antenna to turn the necessary 180 degrees to track the satellite. By adjusting the "on" time or duration, we can adjust the effective rotation speed to correspond to the speed of the satellite.

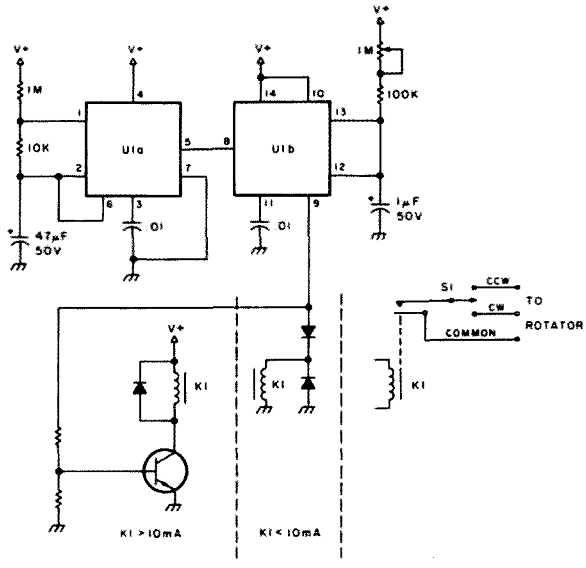

Fig. 3. Automatic control unit. The relay circuit on the left is for relays which draw over 10 mA, the one in the center for relays drawing less than 10 mA, and the circuit on the right shows the wiring of the relay contacts.

The control is made up of two multivibrators and a relay circuit. All parts may be purchased from Radio Shack, and values are not very critical. Integrated circuit U1 is a 556 dual timer. The first timer is an astable multivibrator with a frequency of 40 seconds per cycle (.025 Hz). The other section, U1b, is a one-shot multivibrator with an adjustable cycle length. It is triggered by the astable multivibrator and its output operates the relay. The time constant may be varied by the 1-meg potentiometer.

Two relay circuits are shown. If your relay draws less than 10 mA, you may omit the transistor and diode D3; the IC can drive the relay directly. Be sure to use the appropriate diode to protect the transistor or the IC from high voltages which can be developed when the magnetic field in the relay collapses. The relay is wired in parallel with the rotator switch. A DPST switch is inserted in the line to select clockwise or counterclockwise rotation. The relay must be capable of handling the current and voltage across the rotator switch, so you should check this out before purchasing a relay. You may want to install another switch on the unit to operate a brake if your rotator is so equipped, or to turn the power to the rotator on and off. In my unit, the power switch was integral to the rotation switch. This on-off switch had to be paralleled along with the rotation-select switch.

Calibration of the control unit is easy. Tape a piece of paper behind the control knob for the 1-meg pot. Mark four or five settings on the paper at random. Set the control to the first mark and time how long the rotator takes to turn 180 degrees. This time, in minutes, is marked on the paper. Continue on to the other marks and do the same. You'll end up with a dial calibrated in minutes.

Operation

Operation of the system is not difficult. Using an OSCARLOCATOR or similar device, determine the maximum elevation the satellite will reach and how long it will be above the horizon. Set the tilt axle so that the elevation mast is pointing 90 degrees from the highest elevation reached by the satellite. If the satellite reaches an elevation of 60 degrees above the eastern horizon, point the elevation mast to 30 degrees above the western horizon. If the satellite reaches 40 degrees above the western horizon, point the mast 50 degrees above the eastern. Next, set the elevation to point the

antenna south for an ascending pass and north for a descending pass. If you have everything set up properly, the antenna should be horizontal. If you are using the automatic control unit, set the 1-meg control to the number of minutes the satellite will be above the horizon. Once you have acquisition of the satellite, turn on power to the control unit and everything is automatic from then on. Be sure to turn off the control unit after the pass or the antenna will continue to rotate.

If you are not using the automatic control unit, you will have to adjust the elevation rotator manually. This is really easy; just operate the elevation control from time to time keeping the signal as loud as possible. Remember, you are operating only one rotator. I found that a short burst every two or three minutes will keep your antenna fairly close to the satellite. When not using the system to track satellites, it works well for terrestrial operations. This may be accomplished by positioning the elevation mast so that it is vertical: the antenna will be horizontal and the elevation rotator will act as a conventional rotator.

My experience has shown that the automatic unit works best on orbits below 60 degrees maximum elevation. Above 60 degrees, I usually operate manually. My antenna is a ten-element Twist for 2 meters, a dipole for 10 meters, and I hope to add a small helical for 70 cm. I have had no problems with all of these antennas on my mounting. I have found that operating through OSCAR has been a real pleasure since installing my system. ■

PROGRAMMABLE CTCSS ENCODER

$26.95

• All 37 EIA Tones

• Quartz Accurate

• Less than 1 inch square

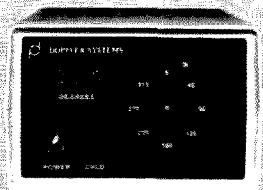
DIRECTION FINDING?

★ Doppler Direction Finding
★ No Receiver Mods
★ Mobile or Fixed
★ Kits or Assembled Units
★ 135-165 MHz Standard Range



★ Circular LED Display
★ Optional Digital Display
★ Optional Serial Interface
★ 12 VDC Operation
★ 90 Day Warranty

New Technology (patent pending) converts any VHF FM receiver into an advanced Doppler Direction Finder. Simply plug into receiver's antenna and external speaker jacks. Use any four omnidirectional antennas. Low noise, high sensitivity for weak signal detection. Kits from $270. Assembled units and antennas also available. Call or write for full details and prices.

SOCIAL EVENTS

DAYTON OH
APR 29-MAY 1

The first International VHF/UHF Conference will be held from April 29-May 1, 1983, as part of the Dayton Hamvention, Dayton OH. There will be technical talks and forums with recognized experts, noise-figure and antenna-gain measuring contests, and a hospitality suite get-together with refreshments. For further information, or to advise us of participation in the noise-figure and antenna contests, please contact Jim Stitt WA8ONQ, 311 N. Marshall Road, Middletown OH 45042, or phone (513)-475-4444 (business) or (513)-863-0820 (home).

DAYTON OH
APR 30-MAY 1

The Dayton Amateur Radio Association, Inc., will sponsor the Dayton Hamvention on April 30-May 1, 1983, at the Hara Arena and Exhibition Center, Dayton OH. Admission is $7.00 in advance and $9.00 at the door (valid for all 3 days). Flea-market space is $15.00 in advance and $16.00 at the door. Other features will include forums, new products, exhibits, women's activities, awards, and special group meetings. For special motel rates and reservations, write to Hamvention Housing, 1406 Third National Building, Dayton OH 45402 (no reservations will be accepted by telephone). For other information, write Box 44, Dayton OH 45401, or phone (513)-849-1720. Make checks payable to Dayton Hamvention, Box 2205, Dayton OH 45401.

GREENVILLE SC
APR 30-MAY 1

The Blue Ridge Amateur Radio Society will hold the Greenville Hamfest on Saturday and Sunday, April 30-May 1, 1983, at the American Legion Fairgrounds, White Horse Road, ½ mile north of I-85, Greenville SC. Admission will be $3.00. For advance sales, write Mrs. Sue Chism, Rt. 6, 203 Lanewood Drive, Greenville SC 29607. Talk-in on 146.01/.61 and 223.46/224.06. For further information, write Phil Mullins WD4KTG, Hamfest Chairman, PO Box 99, Simpsonville SC 29681.

SACRAMENTO CA
MAY 1

The North Hills Radio Club will sponsor its 11th annual Sacramento Valley Amateur Radio Hamswap on May 1, 1983, from 9:00 am to 3:00 pm, at the Placer County Fairgrounds, Roseville CA. Admission is free. Tables will be $6.00 to $8.00 and tailgate sites will be $5.00. Talk-in on 144.59/145.19 (K6IS repeater). For further information, contact Doug Long KB6ZR, 8810 Swallow Way, Fair Oaks CA 95628, or phone (916)-961-0728.

CENTRALIA IL
MAY 1

The Centralia Wireless Association, Inc., will hold its annual hamfest on Sunday, May 1, 1983, at the Kaskaskia College Gymnasium, 3 miles northwest of Centralia IL. Admission to the hamfest is free and there will be no charge for the flea-market and exhibit space (a limited number of tables will be issued on a first-come, first-served basis). Doors will open at 7:00 am for flea-market and exhibit setups. Food and refreshments will be available, as well as plenty of free parking. Talk-in on 147.27/.87 and 146.52. For further information, phone Bud King WB9QEG at (618)-532-6606, Lou Hodges W9IL at (618)-533-4724, or write CWA, Inc., PO Box 1166, Centralia IL 62801.

SANDWICH IL
MAY 1

The Kishwaukee Radio Club will hold a hamfest swap and shop on Sunday, May 1, 1983, at the Sandwich Fairgrounds, Sandwich IL. Advance tickets are $2.50 and tables are $3.00 each. Overnight camping (no hookups) will be available. Talk-in on 146.52 and .13/.73. For more information, contact Howard Newquist WA9TXW, PO Box 349, Sycamore IL 60178.

MELVILLE LI NY
MAY 1

The Suffolk County Radio Club All-Indoor Flea Market will be held on Sunday, May 1, 1983, from 8:00 am to 3:00 pm, at Republic Lodge No. 1987, 585 Breadhollow Road (Route 110), Melville LI NY. General admission is $2.00; children under 12 and wives will be admitted free. Sellers' tables are $7.00 (which includes one admission). There will be refreshments and free parking. Talk-in on 144.61/145.21 and 146.52. For additional information, contact Richard Tygar AC2P evenings at (516)-643-5956.

PUTNAM CT
MAY 1

The Eastern Connecticut Amateur Radio Association will hold its 9th annual radio and computer flea market on Sunday, May 1, 1983, from 9:00 am to 2:00 pm, rain or shine, at the Elks Lodge, Putnam CT (just off exit 96 of Route 52). Tables are $5.00 in advance or $7.00 at the door. Electricity, food, and beverages will be available. Talk-in on 147.225 (K1MUJ repeater). For reservations or additional information, write Don Amirault K1APE, 66 Labonte Road, Box 310, RR #1, Thompson CT 06277, or phone (203)-923-2727.

PARAMUS NJ
MAY 1

The Bergen ARA will hold a Ham Swap 'n' Sell on May 1, 1983, from 8:00 am to 4:00 pm, at Bergen Community College, 400 Paramus Road, Paramus NJ. Admission for sellers is $3.00; buyers will be admitted free. There will be thousands of spaces but tailgating only. Sellers must bring their own tables. Talk-in on .79/.19 and .52. For more information, contact Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855.

DULUTH MN
MAY 7

The Arrowhead Radio Amateur Club will hold its annual swapfest on Saturday, May 7, 1983, from 10:00 am to 3:00 pm, at the Holiday Inn, 207 West Superior Street, downtown Duluth MN. Admission will be $2.50 in advance or $3.00 at the door. Tables (4-foot) are $3.50 in advance or $4.00 at the door. There will be plenty of food, free parking in the ramp, and an enclosed shopping mall for the XYLs. Talk-in on .34/.94. For advanced reservations, room discount rates, or more information, send an SASE to Jerry Frederick N0BNG, 1127 104th Avenue West, Duluth MN 55808.

CEDARBURG WI
MAY 7

The Ozaukee Radio Club will sponsor its 5th annual swapfest on Saturday, May 7, 1983, from 8:00 am to 1:00 pm, at the Circle B Recreation Center, Highway 60, Cedarburg WI (located 20 miles north of Milwaukee). Admission is $2.00 in advance and $3.00 at the door. All 8-foot tables are $3.00. Sellers will be admitted at 7:00 am for table setups. Food and refreshments will be available. For tickets, tables, maps, or more information, send an SASE to 1983 Ozaukee Radio Club Swapfest, PO Box 13, Port Washington WI 53074.

NEENAH WI
MAY 7

The 3F ARC Swapfest will be held on May 7, 1983, from 8:00 am to 3:00 pm, at the Neenah Labor Temple, Neenah WI. Tables (4-foot) are $1.50 in advance and $2.00 at the door. Talk-in on 144.61/145.21. For advance registration, contact Mark Michel W9OP, 339 Naymut Street, Menasha WI 54952.

BREWSTER NY
MAY 7

The Putnam Emergency Amateur Repeater League (PEARL) will hold its 2nd annual indoor hamfest on Saturday, May 7, 1983, from 9:00 am to 4:00 pm, at the JFK Elementary School, Foggintown Road (off Farm-to-Market Road, off Route 312), Brewster NY. General admission is $1.00 and exhibitors' admission is $4.00. Talk-in on 144.535/145.135 and .52. For advance table registration and further information, contact Frank Konecnik WB2PTP, RD 1, 244 C, Carmel NY 10512.

DEERFIELD NH
MAY 7

The Hosstraders will hold their tenth annual Tailgate Swapfest on Saturday, May 7, 1983, from sunrise to sunset, at the Deerfield NH Fairgrounds. Admission is $1.00 for all, including tailgaters and commercial dealers. For a nominal fee, there will be Friday-night camping for self-contained rigs. No one will be admitted before 4:00 pm Friday. Profits will benefit the Boston Burn Unit of the Shriners' Hospital. Last year's donation was $2,622.75. For further information or a map, send an SASE to Norm WA1IVB, RFD Box 57, West Baldwin ME 04091; Joe K1RQG, Star Route, Box 57, Bucksport ME 04416; or Bob W1GWU, North Walton Road, Seabrook NH 03874.

BATON ROUGE LA
MAY 7-8

The Baton Rouge Amateur Radio Club will hold its annual hamfest on Saturday and Sunday, May 7-8, 1983, at Catholic High School, 855 Hearthstone Drive, Baton Rouge LA. There will be forums, and activities for the non-ham wives and children. Talk-in on .19/.79 and .52. For further information, write BRARC, PO Box 4004, Baton Rouge LA 70621.

CADILLAC MI
MAY 14

The Wexaukee Amateur Radio Association will hold its 23rd annual Swap Shop & Eyeball QSO on Saturday, May 14, 1983, from 8:00 am to 2:30 pm, in the Wexford Civic Arena, US 131 North, Cadillac MI. Transportation will be available for anyone flying in and there is camping in the area. Talk-in on 146.37/.97 (WA8SUE). For further information, please write to Wexaukee Amateur Radio Association, PO Box 163, Cadillac MI 49601.

YAKIMA WA
MAY 14-15

The Yakima Amateur Radio Club (W7AQ) will hold the Central Washington State hamfest on May 14-15, 1983, at the Hobby Building at the Central Washington State Fairgrounds, Yakima WA. On Saturday, the hours will be 9:00 am to 5:00 pm with lunch available; on Sunday, 8:00 am to 2:00 pm with breakfast and lunch available. Registration is $4.00 in advance and $5.00 at the door. Activities include regional dealers' displays and a free swap and shop with plenty of tables. Talk-in on 148.01/.61. For pre-registration, contact Dan Haughton, PO Box 9211, Yakima WA 98909.

WAGONER OK
MAY 14-15

The Broken Arrow Amateur Radio Club will hold their annual swapfest on Saturday and Sunday, May 14-15, 1983, at the Western Hills Lodge in Sequoyah Park, located 6 miles east of Wagoner OK (off highway 51). The hours on Saturday will be 9:00 am to 5:00 pm and on Sunday, 9:00 am to noon. Admission at the door is $3.00 for both days or $2.50, if pre-registered. Swap tables are available at the door for $10.00 for both days or $7.00, if pre-registered. There will be dealer and non-dealer displays and many family-fun things to do at the lodge. A cookout dinner will be served on the lakeshore Saturday night. For more information and pre-registration forms, contact Vic Yingst KD5KI at the BAARC, PO Box 552, Broken Arrow OK 74012.

WABASH IN
MAY 15

The Wabash County Amateur Radio Club will hold its 15th annual hamfest on Sunday, May 15, 1983, from 5:00 am to 3:00 pm, at the 4-H Fairgrounds, Wabash IN. Admission is $2.50 in advance and $3.00 at the door. There will be a large flea market, a dealers' display inside, and free overnight camping. Talk-in on 147.63/.03 or 146.52. For more information, send an SASE to Dave Spangler N9ADO, 45 Grant Street, Wabash IN 46992.

EASTON MD
MAY 15

The ninth annual Easton Amateur Radio Hamfest will be held on May 15, 1983, rain or shine, from 8:00 am to 4:00 pm, in the Easton Senior High School Cafetorium, Route 50 at mile marker 66, just south of Easton MD. Donations are $2.00, with an additional $4.00 for tables or tailgaters. Talk-in on 146.445/147.045 and .52. For more information, write Van Herridge WB3HGQ, Box J, St. Michaels MD 21663 or Easton Amateur Radio Society, Inc., Box 781, Easton MD 21601.

ARVA ONT CAN
MAY 15

The annual Southern Ontario Repeater Team Amateur Radio Flea Market will be held on Sunday, May 15, 1983, from 9:00 am to 2:00 pm, at Medway High School, Medway Road (just west of Highway 4), Arva, Ontario. Admission is $2.00 per person. For sellers, indoor or outdoor permits are $1.00 and indoor tables are $2.00 each. Sellers

only will be admitted at 8:00 am; they are required to purchase an admission ticket. For table reservations, write SORT, Inc., PO Box 73, Hyde Park ONT N0M 1Z0, or call Dave Toth VE3GYQ at (519)-473-1643.

EVANSVILLE IN
MAY 15

The Tristate Amateur Radio Society (TARS) will hold their annual hamfest on Sunday, May 15, 1983, beginning at 6:00 am CDT, at the Vanderburgh County 4-H Center, Evansville IN. Admission is $2.00. It will be indoors (air-conditioned) and tables will be available. There will also be an outdoor flea market. Talk-in on 147.75/.15 and 146.19/.79. For additional information and table reservations, contact Hal Wilson WB9FNN, RR #8, Box 427B, Evansville IN 47711.

WRIGHTSTOWN PA
MAY 15

The Warminster Amateur Radio Club will hold its annual hamfest on Sunday, May 15, 1983, from 7:00 am to 2:00 pm, at the Middletown Grange Fairgrounds, Penns Park Road, Wrightstown PA, near Philadelphia. Admission is $3.00 per ham with an additional $2.00 for each 8-foot seller's space. There will be inside spaces but no power will be available. If pre-registered before May 1, 1983, the admission fee will be $1.00 less. Refreshments will be available. Talk-in on 147.69/.09 and 146.52. For more information, contact WARC, Box 113, Warminster PA 18974, or phone Frank AK3O at (215)-968-3133 after 2300 UTC.

KNOXVILLE IL
MAY 15

The Knox County Amateur Radio Club will hold their ARRL-approved 1983 hamfest on May 15, 1983, just off I-74 at Knoxville IL. Tickets are $2.00 in advance and $3.00 at the gate. Camping will be available. For more information or tickets, contact Timothy S. Smith KA9LXB, 229 South Main Street, Monmouth IL 61462, or Keith Watson WB9KHL, 119 South Cherry Street, Galesburg IL 61401.

ATHENS OH
MAY 15

The Athens County ARA will hold their annual hamfest on Sunday, May 15, 1983, from 8:00 am to 4:00 pm, at the Athens City Recreation Center, US 33 and 50. Setup begins at 7:00 am. Tickets are $1.00 in advance and $2.00 at the gate. There will be acres of outside, paved flea-market area at $2.00 per space. Indoor flea-market space is $3.00 and is available on a first-come, first-served basis. There will be food, free parking, and nearby restaurants, recreation area, and the Athens Mall. Talk-in on 146.34/.94. For more information or tickets, write ACARA, PO Box 72, Athens OH 45701, or phone Joe WB8DOD at (614)-797-4874.

ROCHESTER NY
MAY 20-21

The Rochester Hamfest, in conjunction with the ARRL New York State and Atlantic Division Conventions, will be held on May 20-21, 1983, at the Marriott Thruway Hotel and the Monroe County Fairgrounds. Tickets are $4.00 in advance and $5.00 at the gate. Flea-market tickets are $2.00 per space. The banquet will be held at 6:30 pm on Friday and be followed by the annual Funfest at 8:00 pm. The flea market will open at 6:00 am on Saturday; the commercial exhibits, at 8:30 am. The hamfest will close at 6:00 pm. There will be FCC exams given at the Rochester Hamfest for those who have sent Form 610 to FCC, 1307 Federal Building, 111 W. Huron Street, Buffalo NY 14202, by May 1st. A ladies' program will be available. Talk-in on 146.28/.88 and 144.51/145.11. For advance tickets, contact K2MP, 737 Latta Road, Rochester NY 14612. For more information, write Rochester Hamfest, 300 White Spruce Boulevard, Rochester NY 14623.

ROGERS AR
MAY 21

FCC

LICENSE EXAMINATIONS

Reprinted from the *Federal Register*, the following is the text of the FCC's proposed rule which would turn license-examination responsibilities over to amateurs.

PART 0—[AMENDED]

Parts 0, 1 and 97 of the Commission's Rules are amended as follows:

1. Paragraph (a) of § 0.483 is revised to read:

§ 0.483 Applications for amateur or commercial radio operator licenses.

(a) Application for a new or upgraded amateur operator license shall be submitted to the examiners prior to the examination (See § 97.26). The examiners are required to submit the applications of persons passing their respective examinations to the Commission (for Novice Class operator licenses) or to the Volunteer-Examiner Coordinator (for all other Amateur operator licenses). All other applications for amateur radio licenses shall be submitted to the Federal Communications Commission, Gettysburg, Pennsylvania 17325. Only one copy of the application is required.

• • • • •

2. A new § 0.484 is added to read:

§ 0.484 Amateur radio operator examination points.

Generally, examinations for amateur radio operator licenses shall be administered at locations and times specified by volunteer examiners. When the FCC conducts examinations for amateur raduo operator licenses, they shall take place at locations and times designated by the FCC.

3. The heading of § 0.485 is revised to read:

§ 0.485 Commercial radio operator examinations.

• • • • •

PART 1—[AMENDED]

4. Paragraph (a) of § 1.912 is revised to read:

§ 1.912 Where applications are to be filed.

(a) Applications for any class of new or upgraded amateur operator license shall be submitted to the examiners prior to the examination. (See § 97.26) The examiners are required to submit the applications of persons passing their respective examinations to the Commission (for Novice Class operator licenses) or to the Volunteer-Examiner Coordinator (for all other Amateur operator licenses). All other applications for amateur radio licenses shall be submitted to the Federal Communications Commission, Gettysburg, Pennsylvania 17325. Only one copy of the application is required.

• • • • •

5. Paragraph (e) of § 1.925 is revised to read:

§ 1.925 Application for special temporary authorization, temporary permit, temporary operating authority, or interim amateur permit.

• • • • •

(e) Upon successful completion of an Amateur Radio Service operator examination, an applicant already licensed in the Amateur Radio Service may operate his/her amateur radio station pending issuance of his/her permanent amateur station and operator licenses by the Commission for a period of 90 days or until issuance of the permanent operator and station licenses, whichever comes first, consistent with the rights and privileges of the higher operating class for which the applicant has passed the appropriate examination(s), provided that the applicant retains the certificate(s) issued by a VEC for successful completion of the examination(s) at the station location, and provided that the applicant uses an identifier code provided by a VEC as a suffix to his/her present call sign.

• • • • •

6. Section 1.934 is revised to read:

§ 1.934 Procedure with respect to amateur radio operator license.

Each candidate for an amateur radio license which requires the applicant to pass one or more examination elements must present the examiner(s) with a properly completed FCC Form 610 prior to the examination. Upon completion of the examination, the examiner(s) will immediately grade the test papers. If the applicant is successful, the examiner(s) will forward the candidate's application to: (1) The Commission's Gettysburg, Pennsylvania facility for an application for a Novice Class operator license, or (2) a Volunteer-Examiner Coordinator (VEC) for all other classes of operator licenses. A VEC will then issue a certificate for successful completion of an amateur radio operator examination, and will forward the application to the Commission's Gettysburg, Pennsylvania facility.

PART 97—[AMENDED]

7. New § 97.26 is added to read:

§ 97.26 Examination procedure.

(a) Each examination for an amateur radio operator license shall be administered at a location and a time specified by the examiners.

(b) The examiners must be present and observing the candidate throughout the entire examination.

(c) The examiners will be responsible for the proper conduct and necessary supervision during each examination.

(d) Each candidate for an amateur radio license, which requires the applicant to pass one or more examination elements, must present the examiners with a properly completed FCC Form 610 prior to the examination.

(e) The candidate shall comply with the instructions given by the examiners. The examiners must immediately terminate the examination upon failure of the candidate to comply with the examiners' instructions.

(f) At the completion of the examination, the candidate shall return all test papers to the examiners.

8. Section 97.27 is revised to read:

§ 97.27 Examination preparation.

(a) Each Novice code test (Element 1(A)) shall be prepared by the examiner. The examiner must hold an Amateur Extra, Advanced, or General Class operator license. The test shall be such as to prove the applicant's ability to send correctly by hand and to receive correctly by ear texts in the international Morse code at the rate of five (5) words per minute. Subjects for this code test may include the twenty-six letters of the alphabet, the numerals 0–9, the period, the comma, the question mark, $\overline{\text{AR}}$, $\overline{\text{SK}}$, $\overline{\text{BT}}$, and $\overline{\text{DN}}$.

(b) The general code test and the expert's code test (Elements 1(B) and 1(C)) shall be prepared by the examiners. The test shall be such as to prove the applicant's ability to send correctly by hand and to receive correctly by ear texts in the international Morse code at not less than the prescribed speed. Subjects for these code tests may include the twenty-six letters of the alphabet, the numerals 0–9, the period, the comma, the question mark, $\overline{\text{AR}}$, $\overline{\text{SK}}$, $\overline{\text{BT}}$, and $\overline{\text{DN}}$.

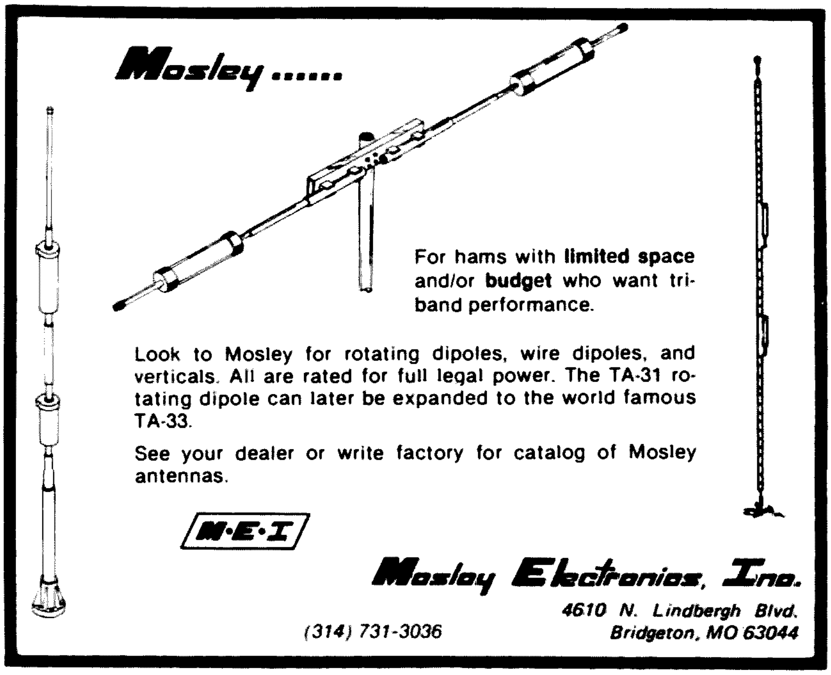
(c) Each written test for the Novice Class operator license shall be prepared by the examiner. The test shall be such as to verify the candidate's knowledge of each general subject area listed for the Element 2 test in the Commission's *Study Guide for the Amateur Radio Operator License Examinations* (PR Bulletin 1035, latest date of issue), but need not be limited to the list of questions approved by the Commission for Element 2 (PR Bulletin —, latest date of issue).

(d) Each written test, except for the Novice Class operator license, will be designed by the Federal Communications Commission (FCC). The FCC will select questions for each test from the list of questions approved by the Commission (PR Bulletin —, latest date of issue). Volunteer-Examiner Coordinator (VEC's) and Amateur radio operators may suggest questions to be included on this list by submitting them in accordance with the instructions in PR Bulletin 1035. VEC's and Amateur radio operators holding Amateur Extra Class licenses may submit questions for any written examination element. Amateur radio operators holding Advanced Class licenses may only submit questions for Element 2 and 3. Amateur radio operators holding General Class or Technician Class licenses may only submit questions for Element 2. For any given written examination element, the percentage of questions on each subject shall be specified in PR Bulletin 1035.

9. Section 97.28 is revised to read:

§ 97.28 Examination administration.

(a) Unless otherwise prescribed by the Commission, each examination for an amateur radio operator license (except the Novice Class operator license) shall be administered by three accredited volunteer examiners (see § 97.30). There will be a team chief. The team chief must hold an Amateur Extra Class operator license. The other two accredited volunteer examiners must hold Amateur Extra Class operator licenses, unless: (1) They are administering telegraphy element 1(A), in which case they may hold Amateur Extra Class, Advanced Class or General Class radio operator licenses, or (2) they are administering written examination elements 2 or 3, in which case they may



hold Amateur Extra Class or Advanced Class radio operator licenses.

(b) Unless otherwise prescribed by the Commission, each examination for the Novice Class operator license shall be administered by one volunteer examiner. The examiner does not have to be accredited. The volunteer examiner must hold a current General, Advanced or Amateur Extra Class operator license issued by the Commission.

(c) Each team chief shall maintain a record of each examination he/she administers. This record shall be maintained in the team chief's station records for one year following the administration of the examination. This record shall be made available to the Commission upon request. The record shall include:

(1) Candidate's name and address;
(2) Candidate's amateur radio station call sign (if any);
(3) Examination location and date administered;
(4) The examination papers;
(5) The examination grades; and
(6) Names of other examiners also administering the examination.

(d) Upon completion of the examination, the examiners shall immediately grade the test papers.

(e) When the candidate does not score a passing grade on an examination element, the examiners shall so inform the candidate and return the application (see § 97.26) to the candidate.

(f) When the candidate scores a passing grade on all examination elements required for the class operator license sought (see § 97.23), the examiners shall certify to the following information on the candidate's application form (see § 97.26):

(1) Examiners' names, addresses and amateur radio station call signs;
(2) Examiners' qualifications to administer the examination (see § 97.30); *and*
(3) Examiners' signed statements that the applicant has passed the required examination elements.

(g) Within ten days of the administration of a successful examination for the Novice Class operator license, the examiner shall submit the candidate's application to: Federal Communications Commission, Gettysburg, Pennsylvania 17325.

(h) Within ten days of the administration of a successful examination for the Technician, General, Advanced, or Amateur Extra Class operator license, the examiners shall submit the candidate's application to a Volunteer—Examiner Coordinator.

10. A new § 97.29 is added to read:

§ 97.29 Examination grading.

(a) Each examination element shall be graded separately by the examiners.

(b) An applicant passes a written examination if he/she answers at least 74 percent of the questions correctly.

(c) An applicant passes a code element examination if he/she proves his/her ability to send correctly by hand and to receive correctly by ear texts in the international Morse code at not less than the prescribed speed.

11. A new § 97.30 is added to read:

§ 97.30 Volunteer examiner requirements.

(a) Each volunteer examiner administering an examination for an amateur radio operator license must be at least 18 years of age and unrelated to the candidate.

(b) Any person who owns a significant interest in, or is an employee of, any company or other entity which is engaged in the manufacture or distribution of equipment used in connection with amateur radio transmissions, or in the preparation or distribution of any publication used in preparation for obtaining amateur station operator licenses, is ineligible to be a volunteer examiner.

(c) Each volunteer examiner shall be uncompensated for his/her services.

(d) Each volunteer examiner administering an examination for the Technician, General, Advanced or Amateur Extra Class operator license must be accredited by the Volunteer-Examiner Coordinator (see Subpart I).

§ 97.31 [Reserved]

12. Section 97.31 is removed and reserved.

13. A new Subpart I is added to Part 97 to read, as follows:

Subpart I—Volunteer-Examiner Coordinators

General

Authority: 47 U.S.C. 154(i) and 303(r).

Subpart I—Volunteer-Examiner Coordinators

General

§ 97.501 Purpose.

The rules in this subpart are designed to proyide for the establishment of volunteer-examiner coordinators to coordinate the efforts of volunteer examiners in preparing and administering examinations for amateur radio operator licenses.

§ 97.503 Definitions.

For the purpose of this subpart, the following definitions are applicable:

(a) *Volunteer-examiner coordinator* (VEC). An entity which has entered into an agreement with the Federal Communications Commission to coordinate the efforts of volunteer examiners in preparing and administering examinations for amateur radio operator licenses.

(b) *Volunteer-examiner*. An amateur radio operator who prepares or administers examinations to applicants for amateur radio operator licenses (see § 97.30).

§ 97.505 Applicability of rules.

These rules apply to each entity that serves as a volunteer examiner coordinator.

Volunteer-Examiner Coordinator Functions

§ 97.511 Agreement required.

No entity may serve as a VEC until that entity has entered into a written agreement with the Federal Communications Commission to do so. The VEC must abide by the terms of that agreement.

§ 97.513 Scheduling of examination.

A VEC will coordinate the dates and times for scheduling examinations (see § 97.26) throughout the areas where communications are regulated by the Federal Communications Commission. A VEC may also coordinate the scheduling of testing opportunities at other places.

§ 97.515 Coordinating volunteer examiners.

A VEC will accredit amateur radio operators, licensed by the Federal Communications Commission, as volunteer examiners (see § 97.30). A VEC will seek to recruit a broad representation of amateur radio operators to be volunteer examiners. A VEC may not discriminate in accrediting volunteer examiners on the basis of race, sex, religion or national origin. A VEC may not refuse to accredit a volunteer on the basis of membership in an amateur radio organization. A VEC may refuse to accredit an amateur radio operator volunteering to be as examiner if:

(a) The volunteer examiner does not meet minimum statutory qualifications or minimum qualifications as prescribed by the rules;

(b) The FCC refuses to accept the voluntary and uncompensated services of the volunteer examiner;

(c) The VEC determines that the volunteer is not competent to perform the function for which he/she volunteered;

(d) The VEC determines that questions of the volunteer's integrity or honesty could compromise the examination(s); *OR*

(e) The VEC determines that no additional volunteers are needed.

§ 97.517 Written examinations.

A VEC will assemble, print and distribute written examinations designed by the FCC (see § 97.27(d)).

§ 97.519 Examination procedures.

At the completion of each examination, a VEC will collect the candidates' application forms and test results from the volunteer examiners (see § 97.28(h)). A VEC will:

(a) Make a record of the date and place of the test; the names of the volunteer examiners and their qualifications; the names of the candidates; the test results; and, related information.

(b) Screen the application for completeness and authenticity.

(c) Forward the application to: Federal Communications Commission, Licensing Division, Private Radio Bureau, Gettysburg, Pennsylvania 17325.

§ 97.521 Evaluation of questions.

A VEC will be expected to evaluate the clarity and accuracy of examination questions on the basis of experience, and to bring ambiguous or inaccurate questions to the attention of the Commission, with a recommendation on whether to revise the question or to delete the question from the Commission's list of approved questions.

§ 97.523 Identification of applicants passing examinations.

(a) A VEC will issue a certificate for successful completion of an amateur radio operator examination.

(b) The VEC issuing a certificate for successful completion of an examination will establish a unique identifier code for each testing session. The identifier code will be appended as a suffix to the licensee's call sign (see § 97.84(f)).

extensive on-the-air testing, until now off limits to most amateurs. The following is the text of the FCC's recent ruling which permits all amateurs to use AMTOR.

PART 97—[AMENDED]

Part 97 of the Commission's Rules and Regulations, 47 CFR Part 97, is amended as follows:

In § 97.69, paragraphs (a) and (b) are revised to read as follows:

§ 97.69 Digital communications.

* * * * *

(a) The use of the digital codes specified in paragraph (b) of this section is permitted on any amateur frequency where F1 emission is permitted, subject to the following requirements:

(1) The sending speed shall not exceed the following:

(i) 300 baud on frequencies below 28 MHz;

(ii) 1200 baud on frequencies between 28 and 50 MHz;

(iii) 19.6 kilobaud on frequencies between 50 and 220 MHz;

(iv) 56 kilobaud on frequencies above 220 MHz.

(2) When type A2, F1 or F2 emissions are used, the radio or audio frequency shift (the difference between the frequency for the "mark" signal and that for the "space" signal), as appropriate, shall be less than 900 Hz.

(3) When type A2 or F2 emissions are used, the highest fundamental modulating frequency shall be less than 3000 Hz.

(b) Except as provided for in paragraph (c) of this section, only the following digital codes, as specified, may be used:

(1) The International Telegraph Alphabet Number 2 (commonly known as Baudot); provided that transmission shall consist of a single channel, five unit (start-stop) teleprinter code conforming to the International Telegraph Alphabet Number 2 with respect to all letters and numerals (including the slant sign or fraction bar); however, in the "figures" positions not utilized for numerals, special signals may be employed for the remote control of receiving printers, or for other purposes indicated in this section.

(2) The American Standard Code for Information Interchange (commonly known as ASCII); provided that the code shall conform to the American Standard Code for Information Interchange as defined in American National Standards Institute (ANSI) Standard X3.4-1968.

(3) The International Radio Consultative Committee (CCIR) Recommendation 476-2 (commonly known as AMTOR); provided that the code, baud rate and emission timing shall conform to the specifications of CCIR 476-2 (1978) Mode A or Mode B.

I need a copy of the schematic and manual for the Wabco 20TS-1 Carryphone type 14H81C transceiver, manufactured by Union Switch and Signal Division. I will pay copying costs.

Jim Cadoret VE6CNY
1066 Edmonton, Alta. T6K 3R4
Canada

I have the operator's manual, but I would like to obtain the full documentation for the AJ830 printer terminal. I would also like to know about any modifications for the Heath H-14 printer.

Mike Cebula
8409 Porter Lane
Alexandria VA 22306

CORRECTIONS

In "Build the Deadeye Dish Controller," which appeared in the April issue of *73*, an incorrect part number was given in the parts list on page 91. The two 1-12 position switches were identified as Radio Shack number 257-183. The correct identification is Radio Shack number 275-1385.

Avery L. Jenkins WB8JLG
***73* Staff**

In the results of *73*'s 1st annual 40/80 phone contest on page 105 of the January, 1983, issue, the 40-meter single-operator champion of Norway was incorrectly identified as LA5YF. The correct winner is Bjorn-Hugo Ark LA5YJ. Our apologies to Bjorn for the error.

Avery L. Jenkins WB8JLG
***73* Staff**

Transcriptions of the CW and/or RTTY receiving tests should be submitted "as received." No attempt should be made to correct possible transmission errors.

Time, frequency, and call letters of the military station copied as well as the name, callsign, and address (including zip code) of the individual submitting the entry must be indicated on the page containing the message test. Each year, a large number of acceptable copies are received with insufficient information, or the necessary information was attached to the transcription and was separated, thereby precluding the issuance of a certificate.

Entries must be postmarked no later than 28 May 1983 and submitted to the respective military commands.

Stations copying AIR send entries to: Armed Forces Day Test, 2045th CG/DONJM Andrews AFB DC 20331.

Stations copying NAM, NAV or NPG send entries to: Armed Forces Day Test, HQ, Navy-Marine Corps MARS, 4401 Massachusetts Ave., N.W., Washington DC 20390.

Stations copying WAR send entries to: Armed Forces Day Test, Commander, 7th Signal Command, Attn: CCN-PO-OX, Fort Ritchie MD 21719.

LETTERS

MISSING THE BOAT

I think we (hams) are missing the boat on the two-GHz band! There are thousands of 2-GHz downconverters out there, and kit prices are cheap.

I would like to see someone come out in print in *73* on transmitting for 2 GHz, how to build for communications such as ATV, etc., or see some advertiser, like Universal Communications, come out with a simple transmitter—as it said a long time back it would, but has not to date.

Keep up the good work at *73*, and thanks for taking time to read my ½-cent's worth.

Larry N. Ingram WA0WOX
Augusta KS

Well, it might make semi-honest men of the 2-GHz converter crowd, so by all means, let's see some transmitters for the band. We'll publish 'em.—Wayne.

NEW CONTEST RULE

I read with great interest your editorial in the December, 1982, issue of *73* and agree with you in taking issue with the PY0SS DXpedition in causing QRM over a 100-kHz segment of the 20-meter band. Your positive approach and suggestion for handling the pileup is a good one and I hope future DXpeditions will take note.

A related subject is that of DX contests. I love contests and participate in them, but can easily see that as they are now conducted they are a source of QRM and irritation to non-contest hams and to a lot of those in the contest, too. The practice of parking on a frequency and calling "CQ DX contest" incessantly is a prime source of QRM and unnecessary spectrum use. To the end that it frequently results in ill feelings in the ham fraternity, contesters and non-contesters alike.

Here on the west coast, DX contesting becomes a matter of primarily working a lot of different countries for multipliers and then working as many JA stations as possible to obtain a high score. It's called running a string of JAs. In recent years, many JA stations, becoming wise to this, refuse to be a part of such antics and now, instead, call CQ themselves. Of course, many of the newer JA hams will respond.

To reduce QRM and to make DX contests more fun for all participants, I propose that contest committees formulate a new rule wherein USA hams listen for and answer foreign stations who call "CQ DX contest" (i.e., USA stations would not be permitted to call "CQ DX test").

Yes, I know that overall scores would be lower and records could not be broken on this basis. However, in addition to reducing QRM, this concept would exercise, to a much greater extent, the operating skills of the USA operators. Everyone would be on more equal footing; rudeness, muscle tactics, and the number of super-power stations would be reduced.

This idea has as much chance of taking hold as a snowball in hell! I wanted to put it out for thought, anyway.

Gary Legel N6TO
Fullerton CA

Oh, let's compromise, Gary, and let 'em call CQ as long as it is above 14,300 kHz. Okay?—Wayne.

VOLUNTEER EXAMINER

As you know, Wayne, the ARRL has requested that the FCC delay any action on a codeless amateur license on the grounds that the amateur community cannot handle the training and examining job. I suspect that it is the ARRL that can't handle the job or prefers not to handle the job.

In your position as a member of NIAC and publisher of *73*, I urge you to assist in finding someone who can handle the job. Most large, well-organized radio clubs could handle the examining and training job if they chose to do so.

Provided I am not bogged down by outside red tape, I will volunteer to handle the job in Lancaster County, by myself if necessary. What I would propose to do is set up training courses through the Adult Education Department of the Lancaster County Voc-Tech schools. I would schedule a Novice class in the fall term, a General class in the winter term, and an Advanced/Extra class in the spring term. I would propose to give the FCC license exam as the final exam in each case. Voc-Tech school courses are supervised by the school administration and the Pennsylvania State Board of Education. I see no need for multiple certified ARRL examiners. In the interest of uniformity, I would prefer to have the FCC supply the exams, but this is not a necessity.

Many communities have education facilities similar to ours. I suspect that most of these educational institutions are eager to add to the scope of their programs. They are subsidized by state and local funds so the tuition is generally low. If anybody would like information on how to approach such an educational organization, I will be glad to advise on the approach.

George S. Gadbois W3FEY
141 Maple Lane
Lancaster PA 17601

Good show, George. My own approach is to push to get Congress to pass a law permitting the FCC to charge for ham licenses, set up a modest fee of, say, $10 for five years of license, and then we will be in a position where we are paying for our keep, so to speak. The next step would be to have ham clubs interested in issuing licenses ante up $1,000 to the Commission which would be put into a special investment fund... perhaps in Treasury Certificates. The interest from this investment would more than pay for our costs to the FCC. The fee would separate the serious clubs from those not truly interested in issuing licenses better than most other criteria and would be a simple test of interest. The clubs would then organize classes for those interested in licenses, ending with both an oral test on rules and theory and a proof of operating competence. Those passing could get their call letters immediately via a desktop computer and a modem connected to the FCC computer in Gettysburg. Indeed, I have discussed this concept with the Commission and not run into any serious resistance... except for the need to get authorization for the fee from Congress. Clubs could bring the deposit fees up to the $1,000 level once or twice a year as they are debited for each new licensee. I suspect that we might be able to embark on a whole new era in amateur radio enthusiasm with such a scheme.—Wayne.

LITTLE BOMBSHELL

I wonder how many hams read the little bombshell, "The Optical Computer," in the February issue of *Scientific American*? The authors have developed an optical analog of the transistor, a device which controls light in a manner analogous to the way a transistor controls electricity. As the title indicates, the authors are primarily interested in applications to digital logic, and with good reason. They have achieved switching times on the order of a picosecond in their prototypes. Would you like a computer that runs at 100 gigahertz?

The device also functions as a linear amplifier and could have profound implications for communications technology. Light energy could be manipulated with the sophistication we now apply to rf. The primary advantage is that the short wavelengths and fast switching times imply tremendous channel capacity. In principle, hundreds of millions of signals could be multiplexed on a single beam. The potential for satellite operations is especially interesting.

Maybe we should get a foot in the door for a ham band at 5 micrometers!

Rapid City SD

SCHOLARSHIPS OFFERED

The Foundation for Amateur Radio, Inc., a nonprofit organization with headquarters in Washington DC, plans to award ten scholarships for the academic year 1983-1984. The Foundation, composed of fifty local area amateur radio clubs, fully funds two of these scholarships from the proceeds of the Gaithersburg (MD) Hamfest. It administers, without cost to the donors, two scholarships for the Quarter Century Wireless Association and one each for the Richard G. Chichester Memorial, the Radio Club of America, the Young Ladies' Radio League, the Edmund B. Redington Memorial, the Amateur Radio News Service, and the Columbia (MD) Amateur Radio Association.

Licensed radio amateurs may compete for one or more of these awards if they plan to pursue a full-time course of studies beyond high school and are enrolled or have been accepted for enrollment in an accredited university, college, or technical school. Most of the scholarships require the applicant to hold at least an FCC General class license or equivalent. The scholarship awards range from $300 to $900 with preference given in some of them to residents of specified geographical areas or the pursuit of certain study programs.

Additional information and an application form can be requested by a letter or QSL/postcard postmarked prior to May 31, 1983, from the below-named scholarship committee chairman.

The Foundation is devoted exclusively to promoting the interests of amateur radio and to the scientific, literary, and educational pursuits that advance the purposes of the Amateur Radio Service.

College Park MD 20740

RTTY MANNERS

For many years, Wayne, you have been in the forefront in the ongoing fight for law and order among amateur radio operators, for more recognition, better operating conditions, more frequencies, and especially for us to clean up our act and be more considerate and gentlemanly—and ladylike—while on the air. It's this last for which I am appealing to you and your publication for help.

I don't know how much RTTY or CW you work. I have never had the pleasure of a QSO with you on any mode, and I was first licensed in 1955. But I am one of those who likes all modes and most of the bands. At present, I operate mostly RTTY, and have since 1958. But I also work a lot of CW and SSB and utilize the 160-acre band down through 2 meters. It is through my diversified operating habits that I have become aware of an increasing problem which only education and awareness can help. This problem is the growing number of "shoot-outs" occurring between RTTY and CW stations.

As you know, for more than thirty years there has existed between RTTY and CW operators a "gentlemen's agreement" setting aside certain portions of the HF bands for each mode. The simple reason for this, of course, was the incompatibility of one for the other. Naturally, the FCC neither recognizes nor has any interest in these self-imposed restrictions, so we can look only to ourselves for help.

It is the rare ham indeed who operates anything besides an SSB rig on HF. And traditionally these are operated on upper sideband in the CW mode and lower sideband in the RTTY mode. Without going into all the technicalities involved, and which you are already aware of, a CW station on the low-frequency side of a RTTY station really

Why the Spider™ Antenna?

—the ultimate in mobile antennas

C. F. (Fred) Shmitka, K6AOI
8554 Lurline Avenue
Canoga Park, CA 91306

↙247

This antenna is truly amazing. I have operated H.F. mobile off and on for the past thirty years or so, and I thought I enjoyed it. But with the combination of a solid state, no-tune rig and the Spider™ Antenna, hey, it's great! No stopping to change resonators or retune. Just switch the rig from band to band and enjoy your QSO's! I used a matching network at the base of the antenna in the old days, but not with the Spider™. The base impedance on all four bands, 10 through 40 meters, is approximately 50 ohms. Another plus for the Spider™ is that it can be used in many varied and unusual installations, plus mobile on most any vehicle. Mount it on the roof of a house or mobile home; use it for back-packing or civil defense work—any portable use. It can be mounted at ground level, using radials laid out on top of the ground.

There is also a Spider™ Maritimer™ Antenna made especially to withstand the corrosive action of salt water breezes and spray. Mast is non-magnetic stainless steel, the fittings are nickel-chrome plated bronze.

For complete information on the Spider™ Antennas and installation accessories write or call Multi-Band Antennas, 7131 Owensmouth Ave., Suite 463C, Canoga Park, CA 91303. Telephone (213) 341-5460.

clobbers the latter, and without even knowing the RTTY station is there. The reverse is true, also. This, then, is where all the shootouts are taking place. One interferes with the other. Tempers flare. Each station then begins jockeying for position, cranks up the power, and starts blasting away at the other. Just listen around a bit and you'll see what I am alluding to. This is total insanity and would never happen if the traditional band-use agreements were observed!

It is not all that rare to find a CW station blithely calling "CQ DX" at 14.090, or a CW rag-chew or traffic net in progress between 3.600 and 3.650. It is a bit unusual, also, to tune across a RTTY QSO around 14.065, but I've certainly heard it. There are more CW violators than RTTY, but only because of two basic reasons: There are more people operating CW than there are operating RTTY; and most hams who get into RTTY are soon made aware of this gentlemen's agreement thing I've been referring to. Neither I nor most of the RTTY bunch I work would even think of moving outside the traditional RTTY turf. On the other hand, when I am operating CW, I stay well clear of the RTTY turf.

Looking at it strictly from the CW man's side, the picture is totally different. Many brag that they've never owned a microphone and that any "deedle-deedle" station is fair game. After all, one holding an amateur Extra ticket can legally operate on all the HF bands, from one end to the other, can't he? You bet, and some do. Not all, of course, for despite the growing evidence to the contrary, there still remains a goodly number of polite and considerate hams whose philosophy is "live and let live" and "everybody to his own taste." Thank God for these!

Most—not all, but most—of the stations interfering with each other in the two modes bear relatively recent callsigns. This, to me, is a sign of ignorance rather than deliberate animosity. A great many newly-licensed amateurs are initially interested only in operating phone or CW. Only a small percentage of newcomers to this wonderful hobby have even heard of amateur radioteletype and enter that facet right off. Therefore, they have little need to acquaint themselves with time-honored traditions not covered in their FCC study guides.

It is for this reason I am appealing to you, as well as to other publications in the hobby, to help. You are in touch. People read what you print. They respect your publication. They respect you. They look to you for new ideas and suggestions. I'm not asking that this letter appear in print, specifically. If you would like it to, go ahead. But it's not enough. Even a mention of the problem in "RTTY Loop" won't be enough, since it will reach only a few RTTY enthusiasts and maybe a smattering of CW people. No, it needs to be brought to the attention of the general ham population, and more than once. An in-depth discussion of the situation in one of your editorials would give you material to write about as well as help enlighten those who need enlightening. Subsequent editorials could contain brief recaps, reaching newcomers as well as reminding others of the situation.

You ask for comments. Here are mine. And thank you for listening.

Bill Skipper K0ARG
Greeley CO

Bill, I sure hope you sent a copy of your letter to QST and that they print it so your thoughts can reach the CW fanatics out there. I doubt if many CW fans still read 73, despite an occasional article on a keyer. I'm not exactly of the mind-set which believes that if God had intended us to whistle at each other he would have built us that way, but I will never be a big fan of CW until it is no longer mandatory by government edict. Once the government no longer forces me to learn the code, I think you'll find me psychologically better able to cope with it. I really hate anything I am forced to do. But trying to reason with CW ops isn't the real answer to your problem. Bill, you are working with a technologically advanced mode of communications, so I suggest that you and all of the other deedle-deedle nuts start designing circuits which CW folks can't bother. Hell, you know that's perfectly possible just as well as I do. In fact, I set up a RTTY station recently using one of the new commercial units and I couldn't believe how susceptible to interferences it was. Why, compared to the circuits we were building in the late 40s, over 30 years ago, this was junk. Bill, it looks to me as if we've gone downhill in 30 years technically. Oh, we had our percentage of bad converters then, too, so perhaps I am over-reacting. I do have to admit to more enthusiasm for the new Tono unit which I got my hands on in Bangkok. Drake is selling it here. Now, that was a lot easier to tune, and it ignored interference fairly well. Oh, it could be a lot better . . . we can design circuits which will just plain reject almost anything that happens in jamming if we work at it. I'd sure like to see some articles submitted to 73 for publication along this line. Remember, a CW station can jam only one frequency at a time, so a good converter should check out both channels, looking for either a signal or a lack of signal in each, and then integrate the results, keeping in mind the asynchronous pattern. It is also getting high time that we started working with higher speed transmissions, developing our 9600-baud techniques and making them work. We might want to go back to 850-Hz shift, too, in order to allow the circuits to check each channel separately and to further eliminate any problems of CW interference. Let's see some work on this. If we are able to work through any attempts at jamming, we will have a nice backup for the gentlemen's agreement.—Wayne.

BASH QUICKIE

I feel that I must respond to your comments concerning Bash books and courses as a method for passing FCC exams.

To begin with, this type of activity has been around for quite some time. Those of us who are former broadcasters remember the days of the First-phone "quickie schools." The schools filled a definite need for an industry to have licensed personnel in a situation where everyone admitted the license was unnecessary.

Now, it is true that amateur radio does not fall completely in line with this reasoning, but it seems to me that if the FCC is going to set up its tests so that someone can sell the answers, then it has only itself to blame. Furthermore, the FCC publishes study guides that a person can use, and if he knows the answers and the reasoning behind the answers, he is likely to pass the test. Is that so different from someone selling the answers?

I think that you are plugging your anti-Bash stand in order to justify a proposal for a code-free license. You point out that it is hypocritical to require code and not technical knowledge, but the two are completely different. Morse code can be quite easily learned, but technical prowess doesn't come easily. Many people still struggle to understand solid-state theory, and while I can build simple transistor rf amplifiers from scratch and I can tell you when a transistor is on or off given certain bias conditions, I couldn't begin to design a transistor amplifier.

Technical knowledge comes at different levels of understanding. It is one thing to know that a basic antenna is a quarter wavelength long, but it is quite another to know how that antenna works with its ground system and how to match it to a 50-Ohm coaxial cable. And I don't think that there are too many hams who would know how to design a ground-mounted vertical system complete with radials and matching network and then put it all together and make it work. I think that in any technical field related to ham radio you will find people who have different levels of understanding, and I think that, quite properly, some of us may have no technical understanding.

I agree with James Burke, author of *Connections*, that any person has the ability to understand something technical as long as the explanation is made simple enough. But has the explanation been made simple? Is understanding how it works worth the time if it is not directly related to your particular interest in amateur radio?

While it may be true that CW scares many people off from ham radio, I think that the technical requirements scare some also. It just happens that of the two requirements, it is easier to "bash" the technical. I do not think that it follows that because we are not overly strict on the technical requirement we should drop the CW requirement. Again, the two are entirely different. One can easily understand Newton's Laws of Motion, but one may not be able to perform the mathematical gymnastics to derive the laws. Furthermore, I do not think that technical knowledge equates with ability to work on equipment. Most hams might understand how their PLL synthesizer works in the hand-held, but I don't think that too many would want to jump in and try to fix it. Is that wrong? Of course not; it's just prudent!

For the record, I am a lawyer. I hold an Advanced license and have flunked the Extra CW once. I have successfully built many antennas, an antenna tuner, simple rf power amplifiers, and a dummy load, all from scratch. I read many technical articles and basic theory articles, i.e., *Solid State Design for the Radio Amateur*, etc., but I certainly can't design that stuff!

Kiernan Holliday WA6BJH/4
Springfield VA

Yep, you're a lawyer.—Wayne.

OPTIONAL CW

I've been receiving your magazine for several years and can honestly say it doesn't lack for controversy. However, I have not seen anything in years to compare with the no-code license hullabaloo in these pages lately.

The no-code license proposal does have its merits, in that it would encourage those with an interest in learning more about radio but deficient at CW skills to pursue that interest on a limited basis in a small part of the radio spectrum.

Opponents maintain that anyone can learn CW. Well, that may be true, and if so, it doesn't screen out the lids. With the Bash books available, anyone can get on the air with only the faintest idea of what they are talking about. Other opponents don't want newcomers to have any easier time of it then they did (a classic argument). How many of you, then, can honestly copy CW at your tested speed?

Perhaps what is needed is some sort of skill examination in conjunction with a standard test of basic theory and radio

laws. This would serve two purposes: First, it would ensure that any exam is cheat-proof. Second, it would encourage the applicant to pursue a "hands-on" learning session about ham radio. Such a skill could be to build a kit. Perhaps the applicant is one of many with an interest in computers and could design a logging program. Maybe even build a small antenna!

Of course, CW could be retained as an elective skill. The point is to get the applicants off to a good start by encouraging an early desire to learn more about radio, and carry it through the rest of their days—not to approach the CW test as a nuisance to be forgotten once the ticket is in hand.

I'm not calling for the abolition of CW. It is an international requirement, and I found it possible to master 20 wpm with some work. It's my favorite contest mode! But, I like chocolate; others prefer vanilla. For an entry-level test, perhaps there is a way to get more newcomers into a dynamic hobby, and I feel that a skill exam may be just the way. If we got more builders instead of OX chasers on 20 as a result, it wouldn't be a bad move.

After all, no-code licenses work well in Europe and Japan. I have yet to hear one good reason why they won't work in the USA.

Peter H. Putnam KT2B
Morris Plains NJ

Troublemaker.—Wayne.

RIDGE RAVE

Just wanted to let you know of the fine customer service afforded me by one of your advertisers.

After having purchased a RTTY interface unit for my computer from Ridge Systems of Acton, Massachusetts, I experienced some difficulty in putting it into operation. I called the Ridge factory, and in a couple of days Dave Beverage, factory engineer, and "Franco," also of Ridge, appeared at my front door.

In a short time they discovered the problem to be in the computer and not their interface unit. They could have stopped right there and left, but instead they proceeded to disassemble my computer, remove the internal PC board, find the problem (a Tandy factory-wired short), and reassemble the machine (a color computer).

After a thorough checkout of the equipment, Dave then gave me extra instruction on using the interface. When he was sure all was well, he and Franco picked up their tools and left—no charge!

The RTTY unit has been operating perfectly ever since, and I not only recommend it to other color-computer owners but find that I can also recommend the company behind it.

Joseph F. Ferullo W1HFF

FUN!

John Edwards KI2U
78-56 86th Street
Glendale NY 11385

THE POSTMAN GETS MAD

Sometimes, I get the feeling that this yearly FUN! poll is getting out of control. Each year, more ballots come in and the work gets harder. Take this year's poll for example, 1,190 of you sent in ballots. This time around it took four people and three computers to tabulate the results (a TRS-80 Model III, an Apple IIe, and an Atari 400, for those of you who care).

This time, for the first time, my mailman spoke his mind. Now, for all of you who addressed your envelopes "Attn: FUN! Poll" or wrote "FUN! Department" in the lower-right corner, let me point out that I live in a rather small, one-family home lodged in an area of New York City that one of my friends calls "Archie Bunker land." My home does not have a mailbox; it has a tiny slot next to the front door. This means that my mailman had to slip each of the letters (up to one hundred a day) through the slot one or two at a time. By the third day, the poor man finally gave up, rang the doorbell, and with a firmly set snarl said, "I don't know what this fun stuff is, but it ain't no fun for me." Before I had a chance to answer, he turned on his heel and trudged away. From there on in, he would merely ring my doorbell, hand me my mail, and say, "Here's your fun mail!" Funny he didn't even answer me when I asked if a mail sack would help.

Here's what you had to say:

ELEMENT 1—BACKGROUND

1) Sex:
- A) Male—89%
- B) Female—11%

A two-percent increase in female amateurs over 1982 and a five-percent increase since 1981. A definite trend is developing.

2) Age:
- A) 15 or below—4%
- B) 16-21—6%
- C) 22-39—37%
- D) 40-59—36%
- E) 60 or above—17%

As the numbers show, not many young respondents to the poll. Either amateurs are getting older or the kids have forgotten how to write.

3) License class:
- A) Novice—7%
- B) Technician—8%
- C) General—26%
- D) Advanced—44%
- E) Extra—15%

More Advanced and Extra holders, fewer Novices, Techs, and Generals compared with last year.

4) Number of years licensed:
- A) 1 year or less—1%
- B) 1-5 years—32%
- C) 6-10 years—12%
- D) 11-20 years—30%
- E) 21 years and up—25%

A breakdown similar to last year's results.

5) Do you have a new (post-March '78) call?
- A) Yes—46%
- B) No—54%

Somehow, those "new" calls just don't seem so strange anymore.

6) How many hours a week do you devote to amateur radio?
- A) 0-1 hour—4%
- B) 2-5 hours—30%
- C) 6-10 hours—42%
- D) 11-20 hours—18%
- E) 21 hours or more—6%

Pretty much the same results as last year.

7) Which HF band do you use most?
- A) 80-75 meters—18%
- B) 40 meters—23%
- C) 20 meters—22%
- D) 15 and/or 10 meters—25%
- E) Don't operate HF—12%

A big dip in 15/10 operation—down 18% in two years.

8) Which VHF-UHF band do you use most?
- A) 6 meters—1%
- B) 2 meters—75%
- C) 220 MHz—4%
- D) 420 MHz and/or up—2%
- E) Don't operate VHF-UHF—18%

Same old story, 2 meters or nothing.

9) Which mode do you use most?
- A) SSB—45%
- B) CW—18%
- C) FM—28%
- D) RTTY—6%
- E) Other—3%

CW is down for the third year in a row.

10) How much money have you spent on amateur radio within the past year? (Include QSL expenses, magazine subscriptions, club dues and other incidental expenses.)
- A) 0-$250—45%
- B) $251-$500—29%
- C) $501-$1,000—20%
- D) $1,001-$2,500—4%
- E) $2,501 and up—2%

Depressing figures, depressing economy.

ELEMENT 2—SOCIAL CHARACTERISTICS

11) Has amateur radio influenced your career choice?
- A) Greatly—27%
- B) Somewhat—24%
- C) Not at all—49%

Static figures.

12) Do you answer QSLs that include a self-addressed, stamped envelope?
- A) Yes—75%
- B) No—25%

No big change here, either.

13) Politically, how would you define yourself?
- A) Conservative—48%
- B) Middle-of-the-road—49%
- C) Liberal—3%

Even more of a conservative tilt than last year.

14) Do you think amateur radio will exist 20 years from now?
- A) Yes—91%
- B) No—9%

More optimistic than last time around.

15) How old were you when you first became a ham?
- A) 15 or below—14%
- B) 16-21—49%
- C) 22-39—23%
- D) 40-59—9%
- E) 60 or above—5%

Just goes to show, you gotta get 'em when they're young.

16) Were you a CBer before you became a ham?
- A) Yes—62%
- B) No—38%

Give me a break.

17) Do you own a home computer?
- A) Yes—41%
- B) No—59%

Someday, 100% yes.

18) Do you think hams, when compared with computer hobbyists, are:
- A) More technically inclined in their hobby—23%
- B) Less technically inclined in their hobby—41%
- C) Both are about equally skilled in their hobby—36%

I think there was some confusion between hobbyists and home-computer users.

19) Do you think that home computing is siphoning people (including youngsters) away from amateur radio?
- A) Yes—71%
- B) No—29%

Noting the obvious.

20) Did you ever use a "cheat book" (not counting the *ARRL License Manual*) to upgrade your license?
- A) Yes—22%
- B) No—78%

The "yesses" are growing.

21) If someone offered you ten million dollars, tax free, on the condition you give up amateur radio forever, would you?
- A) Yes—83%
- B) No—17%

In three years we've gone from one to five to ten million bucks. When we raised the ante from one million to five million, we got 20% more positive replies. Now that we've upped things by another five big ones, we only received a two-percent increase. Guess we hit a ceiling.

22) Do you belong to a local ham-radio club?
- A) Yes—40%
- B) No—60%

A little down from last year.

23) Have you ever attended a ham flea market?
- A) Yes—81%
- B) No—19%

A little up from last year.

24) Do you think the new ARRL leadership is better than the previous administration?
- A) Yes—71%
- B) No—29%

Good news for Newington, but many voters said we should have included a "no opinion" choice. Mea culpa.

ELEMENT 3—OPERATING HABITS

25) Should Novices have phone privileges?
- A) Yes—64%
- B) No—36%

As long as they know the code, right?

26) Do you think US phone bands should be expanded at the expense of foreign-station-only bands?
- A) Yes—81%
- B) No—19%

Are you listening, FCC?

27) Have you ever used a personal computer in connection with your amateur radio activities?
- A) Yes—19%
- B) No—81%

Seems a little low.

28) Is it time to completely deregulate amateur radio by having the FCC turn over all responsibility for ham operation to the amateur community?
- A) Yes—55%
- B) No—45%

Not a mandate by any means.

29) Where do you think the future of ham radio lies?
- A) On the HF bands—9%
- B) On the VHF-UHF bands—91%

So what's holding everyone back?

30) Should we get rid of, or reduce in size, the CW subbands?

A) Yes—66%

B) No—34%

Time to trim the band chart.

31) Do you think religiously-oriented nets have a place in ham radio?

A) Yes—42%

B) No—58%

Amen.

32) Do you think politically-oriented nets have a place in ham radio?

A) Yes—70%

B) No—30%

Free speech lives!

33) If, while tuning across a band, you heard a net of gay hams in progress, would you:

A) Jam it—5%

B) Ignore it—62%

C) Complain to the FCC or some other organization—12%

D) Listen—19%

E) Join it—2%

I think that's a healthy attitude.

34) If, while tuning across a band, you heard a net called "The American Communist Radio Society" in progress, would you:

A) Jam it—7%

B) Ignore it—61%

C) Complain to the FCC or some other organization—15%

D) Listen—17%

E) Join it—0%

See the above comment.

35) If required, could you solidly copy CW at the speed at which you were licensed?

A) Yes—77%

B) No—23%

Either our readers keep in shape or are hopeless liars.

36) If required, could you pass the FCC theory test for your license class without consulting a "cheat book"?

A) Yes—74%

B) No—26%

See above comment.

37) Have you ever purposely operated in an amateur subband you weren't licensed to use?

A) Yes—13%

B) No—87%

These figures have remained about the same over three years.

38) Do you think the FCC affects amateur radio in a positive manner?

A) Yes—15%

B) No—85%

The positive reponses have been creeping upward.

39) Do you ever speak to foreign, non-English-speaking hams in their own language?

A) Always—4%

B) Sometimes—17%

C) I attempt it—23%

D) Rarely—4%

E) Never—52%

No major change here.

40) Do you feel competent to replace the finals in a tube-type rig?

A) Yes—94%

B) No—6%

Tube pins are generally tougher to bend than IC pins.

41) Do you feel yourself competent to replace the finals in a transistor-type rig?

A) Yes—83%

B) No—17%

No pins on transistors.

42) Have you ever built an electronic project from a kit?

A) Yes—97%

B) No—3%

Heath, Radio Shack—take note.

43) Have you ever "home-brewed" an electronic project from a book or magazine?

A) Yes—71%

B) No—29%

Lots of fun.

44) Have you ever designed your own electronic project?

A) Yes—57%

B) No—43%

How about an electronic frequency clearer?

45) What do you think of contesting?

A) Great—15%

B) Good—20%

C) Okay—14%

D) Don't like it—23%

E) Despise it—28%

A sleepless night, sore throat, frazzled nerves—what's not to like?

46) What do you think of DXing?

A) Great—43%

B) Good—29%

C) Okay—11%

D) Don't like it—7%

E) Despise it—10%

The quest for the Honor Roll.

47) What do you think of repeaters?

A) Great—30%

B) Good—13%

C) Okay—37%

D) Don't like them—11%

E) Despise them—9%

Ham radio's answer to Channel 19. Only joking.

48) What do you think of traffic handling?

A) Great—7%

B) Good—31%

C) Okay—28%

D) Don't like it—11%

E) Despise it—23%

In Sam Morse's footsteps.

49) Do you plan to use Phase III Oscar within a year of its launch?

A) Yes—30%

B) No—70%

If Ariane doesn't land in the drink again.

50) Do you plan to use the new 10.1-MHz band within one year of its opening?

A) Yes—12%

B) No—88%

The FCC jumped the gun on this one and actually opened the band before the question got into print. In any event, the question was still valid and 12% of you should be enjoying your new privileges right now. By the way, 40% of you said "yes" last year. What happened?

SELECTED COMMENTS

I think that non-code exam-type licenses should not be allowed. Ham radio has always revolved around CW and should continue to do so.—N6BWJ.

I work in a large ham store and, frankly, the helplessness of today's "Bash" ham is embarrassing. I had a General-class ham ask me if longwave was more powerful than FM.—N6BPL.

Fun, John, Fun! The best part of this response is that I get to cut up Wayne's "NSD" column. Hi!—N1BLL.

A full life is possible without amateur radio. Only a dinosaur becomes too specialized—hobbies are swell but are not essential to life.—Mary MacKenzie, Portland OR.

The FCC plan to have ham clubs handle licensing is the poorest idea they have ever had. The abuse by Bash of the license system would look like harmless child's play compared to the certain sale of licenses to people who don't know the code or can't pass even the simplest technical exam. If amateur radio is to survive, this will not be the way. Ham licenses for a $100 donation, anyone?—KJ7F.

The only foreign language I took was Latin.—K8BNO.

Religion, politics, gays, and reds don't have a place in ham radio. Please forward information to me about anyone who answered "E" for 33 and/or 34.—KA2NNQ.

Amateurs are an unusual class of people. You run into them in a crowd and they stand out as being conservative—serious about their hobby—and willing to help—especially people interested in amateur radio. This is true the world over.—W9MGQ.

This quiz is a good reminder to me of how I've changed my opinions and operating habits over the years.—AJ2X.

How about a hundred questions next year?—KB7WL.

W2NSD/1 NEVER SAY DIE

party publisher to bring unbiased information to users, I can't honestly recommend it.

Remember when you see these great prices that without good software and user information as supplied almost exclusively through system-specific magazines, you are asking for a lot of grief.

SOLVING THE JOBS PROBLEM

With about half of the steelworkers out of work and half of the auto workers looking for jobs, one reads the papers and attends the television panel discussions exhaustively investigating the jobs subject with a growing conviction that things are a bit out of kilter.

On the one hand, I read that the reason our car manufacturers are unable to compete with Japan is that our auto workers are averaging double the American wage, while the Japanese workers are making the average Japanese wage. The immediate response is to wonder at the greed of the unions which pushed the wage scale so out of balance. It appears that if the auto workers who are still working were to accept the average American wage level, there would be no unemployment in that industry. And apparently the same goes for the steelworkers.

Of course, both of these industries have problems more deep-seated than just union-escalated wages. In addition to American auto workers getting double the average wage, they are taking almost double the amount of hours to make a car. The finger here seems to point again at union pressures to prevent automation because it takes away jobs.

I watched this line of "thinking," if that is the right word for it, in the printing business. Unions fought viciously to prevent the modernization of typesetting and printing, with the result that printers have now lost most of the typesetting business, which has been taken over by far more efficient departments in businesses which need the printing. The printing unions, using strikes and terrorist tactics, have managed to cripple what was once a major industry.

Union pressures forced printers to employ hopeless incompetents at incredible wages for years, all the while preventing changes in equipment or systems which would bring economies. When I worked in television, I saw the same union pattern in the theatrical business. Territorial disputes between unions were often vicious. The wages of stage hands, not a terribly exacting job or one calling for much in the way of experience or intelligence, were kept incredibly high by iron control of the union. One had to virtually be born into the union to join, and the theater which did not pay the stage hands between the first and second acts on Friday did not have a second act.

With the era of fast communications and transportation making this a world community, national unions are at a disadvantage trying to control industries. The original idea for unions was wonderful. . . as a bargaining group to counter the tendency of manufacturers to take advantage of workers. And they did. But there was nothing to stop the unions once they got going. They built up money, which is equivalent to political power, and some went right past equity into severe greed, possibly putting to shame the greed of the manufacturers which started the whole thing.

One of these days a whole new concept may emerge. . . one equating to some degree the contributions of people to their income. Yes, I realize that this is anti-socialist and anti-communist and thus probably likely to earn me a lot of scathing replies. The concept of taking as much away from the rich as possible, no matter what they have contributed to the country in exchange for the riches, is deeply rooted. England has done a darned good job of that, with the observable result that the country is a mere shadow of what it was when they had both rich and poor people, not just mostly poor people.

Hams who use their hobby to learn more about electronics are sitting pretty if a concept of getting paid for value ever emerges. The opportunities for working with digital communications is wide open for us these days. I see every sign that the FCC is finally going to break loose and allow us to experiment and develop new communications systems. This means working with RTTY, ASCII, error-correcting systems, packet radio, and so on.

Repeater groups will want to start working with secondary digital relaying systems, possibly using a store and relay memory system in them and interconnecting repeaters for extensive links. The people who use this excuse to gain personal experience in working with and designing circuits will, I suspect, never have to worry about a job. And many will be able to take

this experience and escalate it into the start of a new firm of their own.

There have been a lot of ads looking for support for black colleges, with the headline that a mind is a terrible thing to waste. Well, it isn't just black minds which are being wasted here. A frightening part of America is made up of people with good minds who have been pushed into a life pattern which makes little use of their minds. In school, it is managing to get by via memorizing enough to pass tests and spending most of the waking time screwing around, drinking beer, and so on.

Out of school, one takes a job and gets married, goes home to some more beer and the ever-present television. Going out means McDonald's or Burger King. . . or a bar and an occasional movie. Television takes care of most of the need for entertainment. You've read how many hours a week the average person is in front of the TV set. There's nothing in that schedule for advancing one's education and expertise.

The kid who gets involved with a high-tech hobby in school has a tremendous advantage. There are no bread lines for electronics or computer technicians, only thousands of jobs advertised in the papers from coast to coast. The microcomputer field could easily provide handsome incomes for at least 50,000 people with the ability to repair computers. For a ham with any background in digital work, such as RTTY, getting the hang of computer repair is a snap.

And I don't think I would have much problem in finding work for at least 100,000 programmers. That wouldn't even begin to scratch the surface which is developing in software needs.

There is no easy way to get out of the fix the country has gotten itself into. Unions and other groups who have gotten an edge on the rest of us are protecting that edge with vigorous political power, putting the pressures on the weakest of senators, and you know who I mean. We see them bowing and scraping to the pressure groups every day on the news broadcasts, championing the poor on the one hand, and with the other making sure they stay poor by giving as much as possible to the groups which are getting more than their share and keeping the politicians in office.

Hams, if they don't screw up by wasting their golden opportunities to learn (and that is what *73* is all about), will never have to worry about jobs. I get a bit discouraged when I run into hams who spend 100% of their time wheezing over repeaters or on nets on the low bands, never making any effort to try something new. . . and, at best, writing in angry letters when we present new ideas and technologies in the magazine.

The fact is that despite the slight growth of amateurs, fewer than ever are reading *any* ham magazines at all. Please tell me of what value a ham is to himself or to the rest of us if he not only has no understanding of technology, but isn't even interested enough to read about it? You want to see something interesting? At the next club meeting ask for a show of hands of members who are getting a ham magazine. I think you'll be surprised at how many are not only ignorant about amateur radio, but also have no real interest in learning.

Clubs are a key to not only rejuvenating amateur radio, but also to getting our whole technology moving ahead. Few ham clubs are so dead that at least one member of the club isn't into RTTY, ASCII communications, packet radio, slow-scan television, ATV, OSCAR, or *something* different from rag-chewing or DXing. Get these chaps to give a talk on the fun they are having. . . with some hints on how to join in the fun. If someone is into building, be sure they have a chance to show off what they've built. You could just get some more club members interested. Maybe someone in the club has started a small electronics, ham, or even a computer-oriented business. . . well, get 'em to tell everyone about it. Help them and infect the group with the enthusiasm.

We have enormous potential. We have one of the most fascinating hobbies there is. . . though this is one of the best kept secrets in the country, if not the world. And with the coming need for people who understand communications, never have the prospects been better for using a hobby to provide a stepping stone into business. Thousands of new businesses are needed and will be formed, making thousands more millionaires. Are you going to be part of the fun or one of those watching the next Super Bowl game with a cold six pack at your elbow, wondering how come so many of your ham friends are getting rich?

THE ULTIMATE EMERGENCY

Nuclear war is still more of a science fiction concept than one which has to be faced as a reality. Yet, if you've seen some of the recent evaluations of the situation, it is getting obvious that whether we want to believe that such a war is possible or not, we can no longer just refuse to face the problem.

About five years ago there was a film on television which showed a comparison of the US and the USSR as far as a nuclear exchange was concerned. The SALT agreement set up a situation where both countries agreed not to pursue civil defense protection of the cities, resulting in a sort of mutual hostage situation. Of course, Russia immediately embarked upon a massive development of underground protective areas. We, on the other hand, virtually disbanded our civil defense program. The estimate was that a nuclear exchange between the two countries would probably result in about 100 million Americans getting killed as opposed to perhaps only 20 million Russians.

Not only have they set up extensive protection for their people, but a good deal of their manufacturing has been protected. And their efforts have been continuing, with one recent estimate that their losses might today be down to only five to ten million. Well, these are just figures, so nit-pickers can *argue their validity*, but the basic idea of what has been going on should give us some pause.

Well, the more the USSR outmaneuvers us with missiles and civil defense measures, the more serious is going to be the need for a well-developed emergency communications system. The only thing which can keep us together as a country is the ability to keep some sort of communications between our people and our government. Without that we cease to exist as a country.

The FCC is not unaware of this situation and it has made a major move to do something about this growing need for an emergency communications system which will be available for any emergencies, right on up through a full-blown nuclear war. They started with the National Industry Advisor Committee concept (NIAC), small subcommittees made up of volunteer advisors from industry. These NIAC groups have been around for several years but have not been very active or productive. Perhaps the most active of them has been the amateur radio subcommittee during the last two years.

The Commission in January set up a Long Range Planning Committee (LRPC) made up of top people from our communications industry. This committee has been set up, in essence, as a steering committee for four revamped NIAC subcommittees. The aim for this is the setting up of an integrated emergency communications system.

Though more and more of our government agencies are arranging for intercommunications during emergency situations, nothing has been organized in the way of an overall intercommunications system between government and all civilian radio groups. There seems little likelihood that such an overall system will not depend heavily upon radio amateurs. In this I think we may have a very exciting future ahead of us. Amateur radio is getting to be perceived as needed—by the government, by the communications industry, and by civilian groups.

No matter how bad the battering, when the dust starts to settle, some ham is going to dig his way out of a cave, grab his radio out, and see who is on the air so he can start getting things together. HTs and mobile rigs will be set up for local communications, low-band rigs for area and national communications. The world, what is left of it, will want to know what is happening, and the *chances are that it will be hams* who will be the link.

Rather than wait until we're needed for this ultimate emergency, we'll do better if we get started now setting up the communications systems we may need. We can start with what we've got—improving our repeater systems, linking them through both microwave and low-band links. But if we're going to get very far with this, we're going to have to get going with some badly needed technical developments. Voice communications may do when there isn't much traffic, but if anything serious happens, voice channels will be quickly swamped and we're going to need high-speed digital communications. We won't have that unless we start working on it now.

Over the next few years, I expect that we will be called upon for several things as a group. First, it should not surprise us if both the government and industry start getting serious about the need for the growth of amateur radio. The need for engineers and technicians for the government and industry is getting desperate and no better source of really dedicated technical people has been found than amateur radio. We're going to be called upon to start a big movement to attract the 10-15-year-olds into our hobby. This means new programs for our clubs, cooperation with local schools, and so on.

Amateur clubs are a natural for setting up intergroup communications. In emergencies it is crucial to make it possible for all two-way radio users to have some common link.

As a member of the newly formed LRPC and also a member of the private radio NIAC, I've started a dialog with the communications industry leaders. I have good reason to believe that we can expect to get cooperation with industry and government in developing amateur radio growth. I think we are going to be able to start setting up some repeater-to-repeater communications systems via the commercial satellites, using spare channels. These will start out mostly with voice channels but will gradually change over to digital high-speed channels as we improve our technology.

This isn't anything we can seriously tackle with a bunch of old men staggering around with their walkers. We are going to have to come to grips with the need for youngsters and find out how to attract them. Whether that is going to take a no-code license or what is your problem. You work it out and let me know so we can get some movement ahead. I will say this: Good luck on trying to explain to kids why Morse code is important for the development of the needed high-speed communications system. . . or even for voice communications.

SURVIVING EMP

Electromagnetic pulse (EMP) is a partner of nuclear blasts. Getting the facts about its effects on radio equipment is difficult. We read in some places that solid-state equipment can be expected to destruct anywhere within hundreds of miles of a blast. Then we read that, hell, all you have to do is wrap things in foil to protect them. Truth prabably lies somewhere in between, though more toward ease of destruction than ease of protection. Since it looks as if the government is going to be looking to amateur radio for communications when all else fails, we're going to do our best to get the most accurate information on the subject we can, despite cloaks of secrecy which seem to be thrown up around the subject. We really have to know if we are going to do the job.

When defectors brought us the latest in Soviet fighter planes, our technical people had a merry laugh over the primitiveness of the communications equipment. Imagine being so far in antiquity that they are still using tubes! Golly and har de har har.

The smug chuckles turned sour when someone got to thinking about it and ran some tests. Sure enough, tube gear is able to survive surprisingly large blasts of EMP and still come out working fine. Thus it appears that it is getting time to go back to the old workbench and re-invent tube radios and anything else we want to be usable after a nuclear blast in space.

The transistor came just at the time when we were starting to seriously design truly miniature tubes. Oh, we had some small tubes designed for wartime pocket spy radios and for hearing-aid amplifiers. We made some small "acorn" tubes for VHF purposes such as the 955-9 series. Those came along in the 40s. By 1960, we had even better VHF tubes in the nuvistor, and then tubes were phased out. Today our miniaturization techniques are such that we probably can design some very small tubes to be used in EMP-safe radios, and perhaps this is something in which the government should invest.

In the meanwhile, the rest of us need to know if there is any way to protect our repeater transmitters and receivers, the control circuits, and even our digital RTTY and computer circuits so they will still be around after a surprise.

If we're going to be limited to tube gear after an attack, the type of communications we will be able to provide is going to be totally different than if we can use digital equipment, which would make it practical for us to develop high-speed automatic relaying anywhere in the country. If any readers have good solid information on this, let's start getting it. Please, no conjecture or guesses.

One of the problems involved in getting hard information on these pulses, beyond the restrictions of secrecy, is the difficulty of simulating them for testing. Indeed, there is no test site yet available which can duplicate the short intense pulse involved. A test site in New Mexico has been able to generate an EMP by discharging 160 billion Watts of power, yet this pulse is probably about one-third of what we can expect from a nuclear blast.

The pulse travels particularly well in space, so it is possible that one or two bombs detonated out there could wipe out most of the synchronous satellites. With an increasing amount of our communications being routed via these birds, this could screw things up substantially. That's why, in making long-range emergency communications plans, alternatives to satellites must be considered and developed.

The January/February issue of *Science 83* magazine had an article covering the subject if you want more details.

REVIEW

WHAT DO *YOU* THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

THE AUTEK RESEARCH QF-1A FILTER

Although many active filter designs pass themselves off as "multi-mode" filters, as being equally useful on phone as on CW, very few end up seeing much use in the shack of a dedicated phone operator. One of the few exceptions to this rule is the Autek Research QF-1A filter.

The Autek filter is an active audio filter combining several functions into one package for use in a variety of signal situations. The two-chip filter with built-in LM380 amplifier is capable of driving either a speaker or headphones of any impedance, and it runs on 115 V ac. Two notch filters, a peak filter, and both low- and high-pass filtering is available. And if you like knob-finding, this peripheral device is for you.

Learning to operate the QF-1A is a little like learning how to drive a car with standard shift. All of the controls interact, and like the grinding of gears when you shift without clutching, the ringing in your ears lets you know when you have made incompatible adjustments on the filter. However, the principle behind the QF-1A is simple—it helps you rid the received signal of unwanted components and enhances the remaining desired frequencies. The complexity is necessary to accommodate the wide range of situations found in amateur operating. For CW work, a very narrow bandwidth is desirable, but a wider passband is necessary for SSB. Meanwhile, interfering noise varies from a carrier raging unbridled 2 kHz up from your frequency to the irritating splatter from the back door of kilowatt alley.

Knob Management

In the hierarchy of controls on the filter, the Function Select Switch reigns supreme. This knob allows you to choose between the aforementioned modes of filtering. Peak and notch filtering have opposite effects; the former passes a narrow range of frequencies and rejects the rest, while notch filtering culls out a narrow range and passes the rest. High-pass and low-pass filters remove frequencies from opposite ends of the audio range.

Two of the three remaining controls have different effects depending on the position of the function switch. The Selectivity control determines the bandswitch of the filter while using the peak filter, and it controls the width of the notch when you are in that mode. Peak bandwidth ranges from 14 Hz at a 300-Hz center frequency to 20 Hz at 800 Hz. On the other hand, greater notch selectivity makes the notch shallower and therefore harder to tune.

The center frequency of both the notch and the peak is determined by the Frequency control, which has a range of 250 Hz to 2500 Hz. In operation, it is important to remember that low-frequency filtering creates a narrow passband in the peak filter and varies the signal components rejected by the low- and high-pass filters.

The final control on the QF-1A is the Auxiliary Notch control. This secondary filter is a wide and deep notch, and the control varies the notch's center frequency from 80 to 1100 Hz.

The Bottom Line

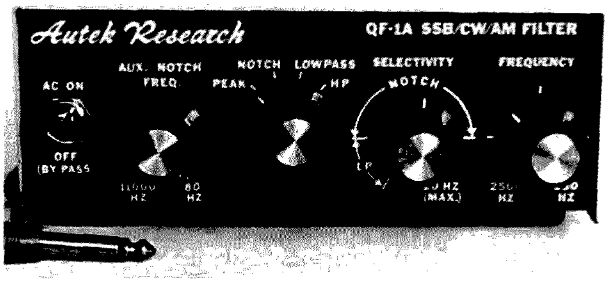
But lest you get wrapped up in all this theory of operation, the bottom line in using the filter is how the signal sounds—and in reaching this objective, anything goes. When using the filter, you are in a double bind of trying to bring a signal out of the mud and trying to keep track of it while the filter changes the signal's quality. Expect some frustration at first, because finding the correct settings requires a practiced ear.

The filter is most effective working against carriers near your frequency. The deep notch can be set on the carrier quickly, and then you can adjust the width to keep other components of the signal. Filtering a nearby voice station is more difficult because a voice signal contains a wider range of frequencies, making it difficult to mask. When attempting to blank another voice station, you may have to settle for simply enhancing the desired signal with the peak filter and ridding the interfering signal of its more irritating qualities.

Splatter is another problematic situation when using the filter; at times there was little I could do, and at other times I could reduce the splatter to a minimum level. Although I did not test the filter in conjunction with SSTV or RTTY transmissions, these are two other areas where the qualities of the QF-1A could be used to their maximum potential.

One of the benefits of using the filter is its built-in amplifier. Whether or not you can clear away flotsam from another signal, the amplifier will help improve the presence of the signal.

Autek includes a full-page table to help get you started with the filter. The table is divided into common interference problems and suggests settings for the controls. These are good starting points, and until you develop an ear for the filter and its controls, it will be necessary to consult the table.



The Autek Research multi-mode filter.

Also included in the manual are alignment instructions and troubleshooting hints, although these units have proved to be extremely sturdy and require little maintenance.

Wrap-Up

I have been very pleased with the QF-1A and its ability to clean up voice as well as CW signals. Several times, I have been forced to use it in deteriorating band conditions, and it made QSOs possible when there would otherwise have been just noise. I also found myself using it with strong stations, not only to clean up the signal but also to put more fidelity in my reception. The filter gives you the opportunity to rearrange the other person's voice to suit the temperament of your receiver and your ears.

The ability to flip the filter in and out with a front-panel switch also proved to be a boon, as I did not have to reach around to the dark end of my transceiver to move it quickly into play. The filter also comes with a full year's warranty for both the components and construction, which is good in comparison to the 90 days other companies provide. After the warranty period, there is a minimum $15 service charge, but I doubt if you will have to take advantage of it.

KENWOOD'S PANADAPTER

I was more than excited to walk into the W2NSD/1 shack and see the Kenwood SM-220 Panadapter on the bench. My first thought was that it sure is nice to work for a company that is "in the business."

"This is one of those station accessories that looks nice but really couldn't improve my operation," I thought to myself.

Boy, was I wrong! After only a few minutes of reading the documentation, I was learning more about the band and station signals than I could ever tell from my "experienced" ear. I soon learned that the SM-220 was a lot more than just a monitor for my transmitted signals. The real beauty of this device is its ability to put into a graphic display the signals that you are receiving.

The SM-220 has several standard functions. Number 1 is its ability to function as a monitor scope. This allows you to display your transmitted waveform from 1.8 to 150 MHz (with some power limitations in the upper VHF range). This function allows you to "see" instantly the signal that you are transmitting. If you are on CW, you can view the keyed waveform and watch for anything from dirty key contacts to too soft a signal. In SSB, you can monitor your signal for the "ideal" waveform or watch your signal deteriorate from excessive audio drive.

Also built into the SM-220 is a two-tone generator and ample diagrams to discern between the "ideal" waveform and one from an overdriven transmitter or defective ALC. All the aforementioned functions are for your transmitted signal. The real kick from operating this scope is watching other signals on the band.

For those of you who are Teletype® operators, the SM-220 displays the standard RTTY cross pattern for tuning in other stations. In addition to telling you if you are tuned to their frequency (sure beats a tuning meter), it will tell you if their space or mark frequencies are exact and if your demodulator or TU has low Q.

The pan-display option (well worth the extra cost) is probably the best feature of the whole unit. It is a plug-in and requires no soldering to install. We have all heard the old-timers refer to panadapters fondly. Now I know why! It is a great feature, and I'll tell you why. Just imagine trying to make that sked you and your buddy try (but not so faithfully keep) on 20 meters. You finally make contact with him and a station comes on your pre-established frequency and tells you that you are QRMing a QSO or net already in progress. Instead of telling your friend "stand by and I'll look for a clear frequency," or "up 5" until you are in the 10-GHz range, all you have to do is look at your SM-220 and immediately see where the "hole" in the band is. It's a fantastic feature! The pan-display option allows you to look at either +/−20 kHz from your received frequency. You can determine if there is a carrier up 10 kHz or an SSB station 3 kHz away. Not only can you see these signals, but you can also tell their relative signal strengths.

And after a short time operating the SM-220, you can develop a fairly accurate correlation between the vertical size of the signal on the scope and the actual signal strength as recorded on your receiver's S-meter. Just think of the ease of operation if you are a contester or even a casual DXer. When the desired station says "listening 14.200 to 14.300," you can look at the display and put your transmitter right into a clear spot.

On top of all of the above features, and an excellent instruction manual (complete with schematics), the SM-220 is a standard 10-MHz oscilloscope. As I said to Jeff DeTray WB8BTH as he walked into the shack with lunch, "I want one."

For additional information, contact *Trio-Kenwood Communications, 1111 West Walnut Street, Compton CA 90220.*

THE YAESU FT-102

Just as the day of the completely homebrewed station has passed, the era of the single-purpose rig has become history. Where once a ham might have had his CW rig for one band and a phone rig for another, today those functions have been integrated into one package. And as technology progresses, more and more functions can be squeezed in.

The Yaesu FT-102 is a perfect example of just how multi-modal today's radios are. This new Yaesu has more modes and filters than Elmer had crystals, which makes it useful for the average ham—the one who sometimes contests (but doesn't necessarily win), sometimes DXes (but isn't on the DXCC Honor Roll), and who exclusively works neither CW nor phone.

Standard features on the Yaesu include

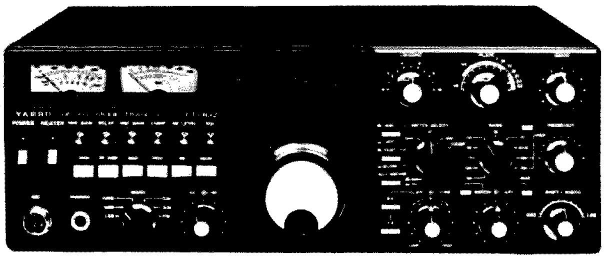
an rf amplifier, speech processor, noise blanker, receiver and transmitter incremental tuning, peak and notch filtering, and i-f passband controls.

Not bad, eh? Optional additions to the rig feature AM as well as 10-meter FM, SSB and CW filters, and an external vfo with push-button frequency input and 12 memories. And the matching speaker possesses two more audio filters for last-minute signal reception clean-up.

All of the WARC bands have been included on the transceiver, which belts 240 Watts into the finals on SSB and CW below 25 MHz and 160 Watts above. With the AM/FM option, the rig has a final input power of 80 Watts on AM and 120 Watts on FM. Frequency is, of course, PLL synthesized, and the audio quality of the transmitter may be tailored for the best intelligibility with your voice.

One of the most obvious features on the front panel of the FT-102 is the series of inset silver knobs just below the dual meters. These knobs operate the lesser-used controls such as the VOX, microphone gain, squelch, and speech compression. The knobs pop in and out so that once set, they are out of the way and will not be inadvertently readjusted. Just below the miniature controls are a series of switches which turn on the rf amplifier, noise blanker, and speech processor, and switch the crystal filters into the circuit. Standard af/rf gain controls are provided as are the agc (fast and slow) and the receive preselector.

A surprising addition is the tone and clarity control, a feature too often overlooked by most other manufacturers. Nobody has ever claimed that ham radio is a hobby for audiophiles, but after four hours of 20-meter cacophony or the crashing of 80 meters in the summer, my ears appreciate the small comfort a control like this offers.



Yaesu's multi-mode FT-102.

Receiving

When I first turned the transceiver on, I thought it was one of the worst-sounding receivers I had ever heard. 14.32 MHz sounded like a thunderstorm in the middle of a drag race, and only the strongest signals could be pulled in with any intelligibility.

That was before I caught the note in the manual which instructs you to turn the rf amplifier off in noisy band conditions. Chalk one up for reading the instructions first. With the amp off, signals became much clearer, but the receiver still possessed fine sensitivity. As I tuned around the band, one of the first things I noticed was the sharpness of the tuning—and this was before the filters were pressed into service. Unlike some other radios, the frequency readout is no more accurate than the selectivity of the front end—what you see is what you get.

As I gained more confidence in manipulating the basic controls, I began trying out the special features. The SSB crystal filter was easy to use and it enhanced selectivity. However, signals were more difficult to tune in because of the resulting sharpness. More difficult to learn were the i-f shift and bandwidth controls. These controls, located on two friction-coupled knobs at the lower left of the front panel, allow you to select the best bandwidth for the band conditons. Width, of course, narrows the passband of the i-f and it is possible to reduce the adjacent QRM without losing too much of your desired signal. Once the width has been set, then you can vary the center frequency of the i-f to focus on the signal. Although extremely useful, I am at a loss as to why Yaesu splined the two together, making two-handed operation a necessity.

When using these controls, be ready to adjust your ears to the changing sound. Together, the two controls have enough range to render unintelligible a previously clear signal.

The peak and notch controls add another level of reception manipulation, this time in the audio portion. These filters are less powerful than the i-f controls and are useful in the less strenuous conditions. Although I do not know if the engineers who designed the FT-102 intended the peak and notch filters to be used in this way, I found that they conditioned the sound to be more pleasing if not necessarily less polluted.

Overall, I found the receiver quality to be one of the best I have encountered. The toughest part of using the receiver is hanging on to a weak signal until you can get all of the controls peaked. While trying to eliminate adjacent QRM, it is easy to mask the signal you want because of the interactive characteristic of the controls. I learned this the hard way in a QSO with a Topeka station who mysteriously disappeared. I thought it was severe QSB working in hand with QRM until I realized that I had put the I-f shift on the wrong side of the signal.

Transmitting

From all reports, the FT-102 has excellent audio, due in part to the adjustments which can be made to tailor the transmitter to your voice. The first step is to cut in the monitor switch to hear your audio as others hear you. Two controls, accessible through the bottom of the rig, adjust high- and low-frequency attenuation. These are set-and-forget controls which need no adjustment unless you start using a different microphone or sell the rig.

The monitor function can also be used to help set the compression on the speech processor and avoid the negative effects of over-compression which void the gain derived from processing. It's no use getting an extra 5 dB if the person on the other end can't understand what you are saying. Short of having another ham tape your transmission and play it back or using an oscilloscope, there is no better way to get your outgoing signal the way you want it. The monitor latches onto the audio in the transmitter i-f so that you get a true indication of quality rather than just amplification of the microphone input.

Another useful transmitting feature is the ALC "peak hold" circuitry. The ALC meter will hold your voice peak for approximately one second to make accurate adjustment of the mike gain control exceedingly easy.

Transmitter tune-up is a variation on the standard drive-plate-loading theme. Instead of varying the plate and loading controls simultaneously for a meter peak, the Yaesu manual recommends moving the load control up in discrete steps and adjusting the plate control until you reach a specified level on the meter.

CW fanatics will be glad to know that they can adjust the pitch of the CW sidetone to suit their taste. The FT-102 provides semi-break in, with the VOX delay controlling T-R switching. Alternatively, the front-panel MOX switch may be used or an outboard switch may be connected to the rear-panel PTT jack. In addition, the instructions for the Yaesu include a section on how to squeeze as much juice as possible from the transmitter when operating on CW.

Accessories

Most notable among the accessories for the FT-102 is the FV-102DM external vfo. Set in a matching cabinet, the vfo expands on the capabilities of the digital circuitry of the transceiver.

The FV-102DM's five-digit display displays kilohertz with a resolution to 10 Hz, and it may be tuned with the tuning knob or by using the built-in keyboard. Scanning speed may be adjusted or you can enter a frequency directly on the readout to move instantaneously to another frequency. The keyboard also offers a stepping rate of ± 20 kHz or ± 5 kHz, and both the keyboard and the tuning knob may be disabled when operating from the frequency memory bank.

Four tuning rates may also be selected for the analog control, and any of these rates may be multiplied by a factor of 10 for super-fast tuning. A series of switches allows you to put the receiver and transmitter on your choice of vfos or place either under the control of the stored frequencies.

A second accessory, the speaker/filter combination, offers the final word in signal conditioning. The two filters used jointly can create a speaker response suited to any environment. You can attenuate highs or lows as well as choose your bandpass width. The speaker itself has been designed for communications responsiveness, and even without the filters the sound is exceptionally sharp and clear.

Finally, the manuals which accompany both the FT-102 and the accessories have been well designed. They include clear and concise operating instructions in addition to tables which outline common control positions for a variety of situations. I am also happy to report that both have extensive theory-of-operation and service sections. Although the sections are certainly far from being comprehensive service manuals, they do cover most of the maintenance and troubleshooting procedures that the average ham would need to keep operating at peak capacity.

Although some would question the need for all of the options which the FT-102 and its accompanying peripherals present, I consider them welcome additions to the shack. Good operating requires access to a variety of techniques, whether you are running a phone patch or chasing DX, and this transceiver offers the necessary flexibility for successful hamming.

HEIL HC-3 MICROPHONE CARTRIDGE

Bob Heil, 1982 Radio Amateur of the Year, never stops moving. He has more irons in the fire than any other ten people, and most of them are deeply involved with audio and amateur radio. Since 1966, Bob Heil has been a sound manager on the road with such groups as The Grateful Dead, The Who, Dolly Parton, Billy Graham, and many others. He has wide experience with radio- and TV-broadcasting studio audio systems and has written many books on the subject of good audio, including *A Practical Guide for Concert Sound.*

Long ago, Bob discovered that speech intelligibility is a function of clean audio —audio that is not cluttered with distortion. Distortion comes from intermodulation products caused by the combination of audio frequencies whose fundamentals may be below the audible range... say at 50 to 200 Hz. These will pile up on one another and produce combination frequencies that are within the audible range... hence distortion. The effect of this low-frequency rumble is to render the audio less intelligible and "muddier." In addition, as you tune across an SSB signal, it often is heard a long way from the center frequency because of these intermodulation distortion products. A good, clean SSB signal is more sharply defined, and the low and high cutoff frequencies are closer together. The voice sounds more natural... almost as if the person were present in the room with the listener.

Bob is a believer in the fact that good, properly designed and executed speech can be heard over the caterwauling of a DX pileup, just as a singer can be heard over 120 dB of drums and guitar... provided the right things are done. The right things have to do with articulation and sibilants. Articulation is the ability of the mind to hear and clearly understand what is being articulated from a source... such as a transmitting station. Sibilant sounds—s and t sounds—are necessary for intelligibility... and they must be reproduced faithfully; otherwise, grass sounds like grapf, and callsigns become greatly confused.

Bob and his engineers found that there is another quality called balance, which means that there must be a balance between the audio frequencies between 1200 and 1500 Hz, and those at the bottom and top ends of the speech range. The critical frequencies for sibilants and articulated syllables lie in that range... and the microphone or audio system must produce exactly the right level of these frequencies as clearly and cleanly as possible, i.e., without distortion and properly balanced with respect to the rest of the spectrum.

Unfortunately, many hams falsely equate lots of bass response with good audio. While bass is important, it is not everything.

The goal should be to make the transmitted voice sound as natural and as close to the original as possible.

The HC-3 microphone element ($19.95) does just that. . . it reproduces the natural voice as closely as possible to the original by giving proper emphasis and balance to the sibilant range without neglecting the highs and lows. It rolls off rapidly below about 450 Hz and above 2,400 Hz and is designed as a replacement element for almost any amateur microphone.

In my case, I substituted my faithful old Shure 444 dynamic element with the HC-3. The first thing I noticed was that the output level of the HC-3 was not quite up to that of the 444. Bob Heil explained that this was so because the necessary fidelity and frequency balance could not be obtained with high output. The development engineers produced the best possible trade-off between output and articulation for the desired audio quality. The level was taken care of by merely increasing the microphone gain until the output level for the transmitter was correct once more.

I enjoyed SSB contacts on 160 meters, 40 meters, and 20 meters using the Heil element. Most reports were unsolicited, although I did ask several stations to give me critical reports. The consensus was that the HC-3 produced clear, natural-sounding audio that was very crisp and easy to tune. Several stations commented on the sharp tuning of my signal, and complete absence of splatter or distortion. Most of them mentioned that my voice sounded as real as if I were in the same room. . . and they imagined that it must sound exactly like me. Others commented about the "presence," which I took to mean some sort of attention-getting quality or "authority."

In general, the reports were uniformly and unanimously favorable. Since those tests with my Astro 102BX, I removed the HC-3 cartridge from my 444 and replaced the original element. The cartridge was then loaned to Avery Jenkins WB8JLG to play with and use on his own rig in order to see what effect it would have on audio quality and reports. Avery's report:

"My initial reaction as I installed the new Heil cartridge into my microphone was that things sure have gotten smaller since the people at Turner put the finishing touches on my old single-sideband special. Where the original microphone took up the full diameter of the grill—about 1½ inches—the Heil cartridge is about the size of my thumbnail. The size differential was so great between the two components that I had to tape the Heil cartridge to the inside of the grill so it would not just flop around in there. The instructions supplied with the cartridge note that mechanical shock is not healthy for the cartridge, so I surrounded it with foam cushion, although I was not sure what effect the padding would have on my audio.

"I need not have worried; all of the reports received pronounced my audio as healthy. Although I cannot vouch for any gain in my signal strength, I suspect that the cartridge made some effect in marginal signal conditions, particularly when fighting heavy QRM. It is at those times when your audio needs that added presence to distinguish it from all of the other signals coming through the speaker at the other end.

"The audio from your signal encounters many adversities on the way to its destination, so, it makes sense that you would want it to be as clean as possible from the start. And if you are processing your audio, intelligibility becomes even more of a factor as you give some of it up for the added punch of compression.

"One of the more common problems with amateur-station audio is an excessive bass component, a result of both the transmitted audio and the audio response of the receiver and its speaker. With my Turner, this was a problem, so I asked my contacts on 15 meters to give me an honest rating of my voice as they heard it.

"None felt that the signal was too bassy. Some of the stations that I was getting a good signal into also noted an interesting effect; they suggested that I sounded similar to other stations using a linear—apparently, the audio had the kind of power normally associated with a kilowatt or more.

"Those comments are the kind I like to hear. Although the Heil cartridge may not give you the raw strength of a linear, it does rectify one of the more commonly overlooked problems in amateur operating—intelligibility. And in many cases, it is a basic factor like this that can make or break a successful QSO."

The Moscow Muffler.

AEA'S MOSCOW MUFFLER™ WOODPECKER BLANKER

There are few hams, indeed, who have not been annoyed, enraged, disappointed, frustrated, and driven to blind fury by the Russian OTH radar whose rat-tat-tat-tat-tat pulses have disrupted amateur communications for the past five years or so. The woodpecker has shown up on frequencies below 30 MHz almost at random, except that—more often than not—it stays very close to the MUF. . . and irregularly changes frequency by hundreds of kilohertz. . . up and down the bands where DX communications are the best at any given time. We've all had weak stations obliterated just as something interesting was about to be said, and we've even lost rare ones now and then because of the dratted woodpecker.

From time to time, articles describing blankers that purport to deal with these pulses have appeared in the ham literature, and some of the blankers have been successful. Virtually all have been designed for use in a receiver only, and a few of them have been designed for only one type of receiver circuit. None has been available in ready-made form (as far as the writer knows), with the exception of some very recent equipment whose built-in noise blankers have incorporated variable pulse width and repetition-rate blanking. These—sometimes—effectively get rid of the noise. Most only reduce it from impossible to barely acceptable.

What has been needed is a pulse blanker that will absolutely eliminate the pulses, a blanker that can be used with a transceiver or a receiver, and one that is readily available for anyone at a reasonable price. Until now, that need has not been met.

At the Boxboro Hamfest last fall, Advanced Electronic Applications showed up with the prototype Moscow Muffler™, an affordable and easily-employed woodpecker blanker that could be inserted into the coaxial cable between rig and antenna, which would wipe out the woodpecker with only a few simple adjustments. It was an instant success, not to mention a mild sensation. The demonstration allowed one to knock the pulses down from an S9 + 20-dB level to less than about S2 on the test receiver.

Naturally, it wasn't long after the demonstration that we asked for a unit to test. . . and it wasn't very long after that that the WB-1C showed up on our doorstep—that is, the doorstep of the W2NSD/1 ham shack. Good-bye to frustration and anger, and hello to living with the Russkis' efforts to drive the West bonkers. Come to think of it, I'll bet a few UAs don't like it, either.

Description

There are two models available: the WB-1 and the WB-1C. Either one will interface successfully with any communications *receiver* by placing the blanker between the antenna and the receiver antenna-input terminal. Usually, this is done by means of a short length of coaxial "patch" cable with PL-259 UHF-type plugs at each end to mate with the SO-239 chassis connectors.

The WB-1C model, however, is intended for use with a *transceiver* in which the output power is less than (or can be reduced below) 150 Watts. No internal modifications or changes of any kind are required with either model woodpecker blanker, but the transceiver model has an automatic antenna relay that is actuated by sensing rf power in the transmission line and disconnects the delicate circuitry from the outgoing rf during the transmit cycle.

The woodpecker blanker lives in a black box measuring about 6" wide × 5" deep × 2" high. An attractively-screened front panel contains an on-off indicator (LED) plus an on-off power switch (you must furnish your own source of 12 volts dc or buy the available accessory ac/dc converter available from AEA). Next to the power push-button is a gain push-button that allows you to select an internal 6-dB amplifier for bringing up those weak, hard-to-copy signals. Next to that is the blanker on/standby button, and next to that is the rate-selector button offering a 10-Hz or a 16-Hz repetition rate. Two knobs are provided for varying pulse width and pulse sync.

On the rear panel, you'll see the power-input jack, the *antenna* and *transceiver* (receiver) connectors, and a ground terminal. Also, there is a carrier-operated-relay adjustment (COR ADJ) shaft with screwdriver slot. This permits you to adjust the drop-in/drop-out relay timing so that the antenna is disconnected from the receiver for only as long as necessary during the transmit/receive cycle. The box weighs about 2 pounds and looks mighty nice sitting next to the transceiver. Let's see how it works.

Operation

WARNING! Do not connect your transceiver output to the "antenna" connector; connect it, instead, to the "transceiver" connector. Doing otherwise will ruin the unit and void the warranty.

After connecting the antenna to the antenna terminal of the WB-1C and a patch cord between the transceiver terminal of the WB-1C and your transceiver output, connect the 12-V-dc source. The AEA AC-1 wall adapter will furnish the needed voltage and 575-mA current (center-pin positive). Ground the terminal marked ground to your station ground.

Turn on your transceiver, and if it has its own noise blanker, make sure that it is off. Note that no signal will reach your receiver until you turn the power switch ON (if you have the WB-1 receive-only model). With the WB-1C, you will hear signals immediately. You may now select the wide-band preamplifier, if you like, to bring up the level of weak signals above 14 MHz or so. Frankly, I did not need the preamp, but tried it anyway. It works. . . but more about that later.

When the woodpecker appears, depress the BLANKER button and select the 10-Hz rep rate with the button next to it. Advance the WIDTH control to approximately the 2 o'clock position and slowly tune the SYNC control knob until the woodpecker signal disappears or is much reduced in level. Then, slowly reduce the blanking pulse width by rotating the control counterclockwise, and fine-tune the SYNC control. I found the 10 o'clock position to be about right for WIDTH. Excessive width causes more loss of signal than necessary.

Special Condition

The woodpecker apparently transmits from at least two locations: one in Siberian Russia and the other in European Russia. You will find that in most cases you can adjust the blanking to reduce pulse amplitude by 45 to 50 dB. If it's less, this could be due to poor adjustment, but more likely to multiple-path propagation where the delay or phase lag causes your SYNC control to lock on the primary pulses but not the delayed or out-of-phase ones. Perhaps lack of synchronizing could be due to both woodpeckers jamming at once. Incidentally, the woodpecker sometimes operates at a 16-Hz rate, so it might be wise to try that if you don't get all the pulses at 10 Hz. In my case, I did not need the 16-Hz rate, as every time I heard the woodpecker it was using 10-Hz pulses.

Since I operate mostly CW, I was anxious to find out how much of the incoming signal I was going to lose because of the blanking. (Remember, "blanking" means

just that . . . it knocks out a portion of the received signal in lock-step with the woodpecker. You actually are listening to "nothing" with each pulse blanked out.) At some Morse speeds, parts of the characters are lost, but an adjustment of sending speed will help. The blanking action bothers CW more than phone.

Sometimes the synchronizing may be difficult. If so, try changing the agc control of your receiver from slow to fast, or vice versa. If that doesn't help, turn the blanker OFF and ON again quickly.

Other Comments

I have a wideband, low-Q, multiband vertical antenna system that allows me to operate on the ham bands of 10, 15, 20, and 40 meters. When I tried this antenna with the preamplifier ON, I was assaulted by commercial signals from some other band—possibly forty meters—when listening to the 20-meter band. This was the result of some signal being picked up and amplified by the WB-1C preamplifier. It disappeared when I switched off the preamp. It also disappeared when I changed to a single-band antenna or when I tuned on another band.

I was worried about the problem, so I called Mike Lamb at AEA. He said that he had another report of a similar problem, and found it was due to the presence of a very strong local FM station close to the QTH of the person who complained. This also turned out to be the case in my QTH. Mike's suggestion of a low-pass filter between the antenna and the WB-1C solved the problem by trapping out the high-level energy in the 88-108-MHz region that was mixing with desired signals and amplified by the on-board preamp.

It turns out that I don't have the problem now because the addition of the low-pass filter solved it. If necessary, I could have turned the preamp OFF and solved it, too, but I did want to be able to boost low-level signals on rare occasions.

The use of an antenna tuned to the band you are on and no other band also will reduce the problem greatly. However, spurious response is likely to be a problem only in those rare cases where you have a strong, local, interfering signal from a commercial station and choose to use the preamp without using a low-pass filter in the circuit.

The Blanker and You

Will you like it or hate it? If you suffer from the ravages of the wild woodpecker, you are likely to love it. You will note that it takes some adjustment to make it work properly, and—like everything else—experience and practice pay off. I can't foresee anyone who will hate it. In the case of someone who never operates where the woodpecker is found . . . he won't need the WB-1 or WB-1C anyway (lucky soul). For the rest of us poor, suffering hams, the AEA Moscow Muffler is nothing short of a boon and a delight. The WB-1C is worth every penny of the $149.95 price ($129.95 for the WB-1), and—best of all—it will kill the woodpecker *DEAD!* The AC-1 is $14.95. For more information, contact *Advanced Electronic Applications, Box C2160, Lynnwood WA 98036.* Reader Service number 490.

SLINKY DIPOLE TUNING CHART

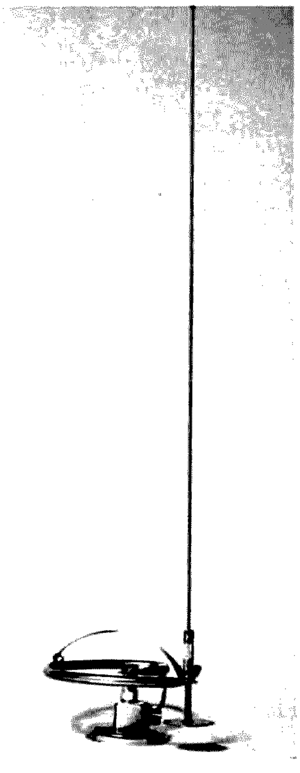
The Blacksburg Group has announced that it has the information necessary for tuning up the Slinky Dipole on the new 10-MHz band. The antenna needs no attachments for use on this frequency, but it does require an additional tuning chart.

The company is offering the chart free of charge to all Slinky Dipole owners, regardless of when or from whom they bought the antenna. Slinky Dipole owners should send a large (#10), stamped, addressed envelope to The Blacksburg Group to receive the information. If writing from overseas, you need only send your name, address, and two IRCs.

For more information, contact *The Blacksburg Group, Inc., PO Box 242, Blacksburg VA 24060; (703)-951-9030.* Reader Service number 477.

COM-RAD'S DDRR WITH RANGE EXTENDER

A unique accessory called the Range Extender now offered by Com-Rad Industries can be added to their very successful DDRR two-meter antenna (a DDRR and Range Extender combination is also available for 220 MHz). The Range Extender is a tapered stainless-steel whip and mounting base that can be attached to the end of the ring element of the DDRR. The unique feature is that the DDRR can be used alone or with the Range Extender without retuning. The transceiver sees no change in load. The use of the Range Extender does not, in any way, detract from the DDRR's ability to reject intermod.



Com-Rad's DDRR with Range Extender.

Tuning is accomplished simply by adjusting the stainless-steel capacity disc's height above its ground plane by turning the threaded stud attached to the disc and tightening the wing nut. The disc system supplements the bronze strap that was formally used and reduces the height of the antenna another two inches from its already extremely low profile. Owners of Com-Rad's DDRR antennas with bronze tuning straps may return their units to the factory for conversion to the disc tuning system at a minimal cost. For more information, contact *Com-Rad Industries 1635 West River Parkway, Grand Island NY 14072; (716)-773-1445.* Reader Service number 476.

SATELLITE-TRACKING PACKAGE

Computer Applications has announced Pathfinder II, the new multi-option satellite-tracking package for Apple computers. Pathfinder II has been designed to operate with a minimum of user-supplied information.

This program will track any circular-orbit satellite from anywhere in the world. Tracking is conducted in real time, and the path may be mapped on either a world or US map, using high-resolution graphics. Maps and tables of data may be printed on the Epson MX™ printer.

Pathfinder II comes complete with satellite-tracking information for OSCAR 8, NOAA 6 and 7, and the RS satellite series 3-8 already on disk. Information for other satellites may be added to the program's data base.

In addition to predicting future orbits and reference orbits, the program will compute and present a summary of orbital characteristics, using an exclusive, high-speed, accurate prediction algorithm.

For additional information, contact *Computer Applications, 3628 A Court, Oxnard CA 93033.* Reader Service number 486.

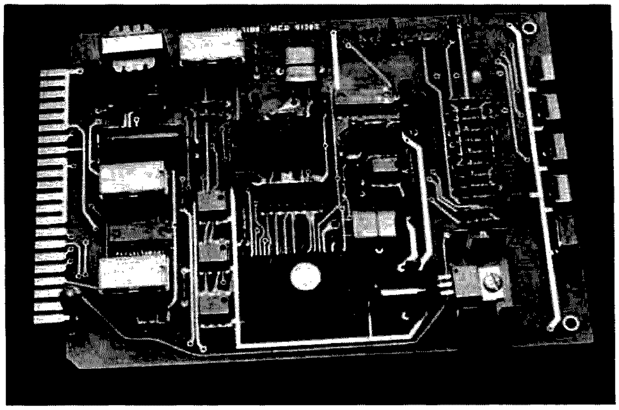
MCD 01 REPEATER CONTROLLER

Micro Concepts and Design Company has released its MCD 01 Repeater Controller, which provides the best quality in repeater control using the highest technology available for controller application.

The MCD 01 utilizes a Motorola MC 68705 microprocessor as the heart of the unit, combined with the latest in programming techniques. The MC 68705 contains 2K of EPROM and 112 bits of usable RAM. The stored program is protected in ROM against loss due to power failures. With this combination, a highly reliable and easy-to-maintain controller can provide a repeater with sophisticated control techniques never before seen at a modest cost.

A single-chip ITT 3201 DTMF decoder is used to decode all 16 touchtones™ used in repeater operation. This gives the repeater owner the capability to use any or all of the 16 DTMF tones. The chip contains both high and low filtering to prevent falsing.

Other features include 4 repeater access modes (carrier, touchtone, touchtone or PL, and PL only) and 3 autopatch/autodial access modes. The autopatch feature includes both touchtone and rotary dial capability. You may use any number of digits for any control or access command, and telephone line or auxiliary receiver inputs may be used for control purposes without disturbing normal repeater operation. The functions may be disabled together or separately.



The MCD 01 Repeater Controller.

A programmable subaudible tone encoder/decoder with 32-tone capability is included in the control unit. The encoder/decoder contains the necessary audio filters for the tones.

The primary design concept in the MCD 01 is to provide needed and practical features with complete operator control and easy-to-maintain circuitry. All components used in the controller are easy to obtain, and they have been mounted on a high-quality double-sided PC board with a 22-pin edge connector.

The MCD 01's compact size, high-quality components, and fine technology make it a perfect repeater controller for the discriminating repeater owner/operator.

For further information, contact *Micro Concepts and Design Co., PO Box 19786, Orlando FL 32814; (305)-298-3026.* Reader Service number 487.

MFJ-1220 RTTY/CW COMPUTER INTERFACE

The new MFJ-1220 RTTY/CW Computer Interface is a terminal unit that provides TTL/CMOS and RS-232 levels for computer interfacing.

Unlike phase-locked-loop demodulators, this is an optimum design using individually-tuned active bandpass filters. It has separate mark and space channel filters, a CW filter, and a post detection lowpass filter for excellent weak-signal and high-interface RTTY/CW performance.

It takes received RTTY/CW audio from your transceiver, demodulates it, and provides TTL/CMOS and RS-232 levels for interfacing with nearly any computer. A program (not included) is used to provide RTTY/CW text.

For RTTY transmission, your computer drives the AFSK generator to provide FSK transmission using the microphone or phone-patch input of your SSB transmitter, or it can directly key the FSK input of your transmitter.

For CW transmission, your computer drives the high-voltage keying currents of the MFJ-1220 which then provides grid-block or direct keying for your transmitter.

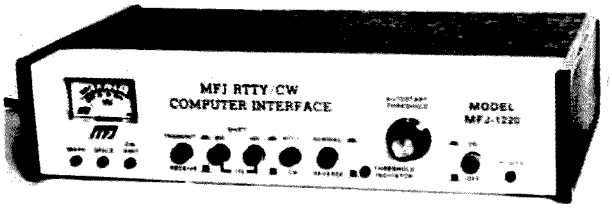
The RTTY/CW Interface transmits and receives all standard RTTY shifts of 170, 425, and 850 Hz to cover all amateur, commercial, and military traffic to over 100 wpm. It uses the standard space tone of 2125 Hz and mark tones of 2295, 2250, and 2975 Hz.

Meter, mark, and space LEDs aid in precision tuning. The mark and space LEDs also indicate mark and space transmissions. A normal/reverse switch reverses the polarity of the mark and space for receiving. A CW transmit LED provides visual indication of CW transmission. A sensitive autostart feature keeps noise from activating the computer or printer when there is no RTTY signal.

The MFJ-1220 operates on 12 V dc or 110 V ac with an optional adapter, the MFJ-1312. The cabinet is eggshell white with walnut grain and top. It measures 10 × 2 × 5 inches.

MFJ provides a 30-day money-back trial period. If you are not satisfied, you may return it within 30 days for a full refund (less shipping). MFJ also provides a one-year unconditional guarantee.

For additional information, contact *MFJ Enterprises, Inc., 921 Louisville Road, Starkville MS 39759; (800)-647-1800.* Reader Service number 479.



MFJ-1220 RTTY/CW Computer Interface.

YAESU HF TRANSCEIVERS

Yaesu Electronics Corporation has announced two additions to its line of HF transceivers.

The FT-980 is a full-featured 160-10-me-

The Yaesu FT-980 HF transceiver.

The HC-200 antenna tuner from Encomm.

ter transceiver which also includes a general-coverage receiver section. Providing a nominal 100 Watts rf output from a low-distortion, high-voltage final amplifier, the FT-980 is set up for full QSK with silent solid-state switching. The receiver section is designed for wide dynamic range and versatility in filter selection. An audio peak filter, i-f notch filter, variable pulse-width noise blanker, variable i-f bandwidth with i-f shift (passband tuning), and an audio-shaping control round out the receiver features. The FT-980 is controlled by an 8-bit microprocessor, which allows storage of frequency and mode into memory while also allowing the programming of subband limits for Novice-, Technician-, General-, or Advanced-class operators. Direct keyboard entry of frequencies provides instant QSY without the need to rotate the main tuning dial.

The FT-77 is an extremely compact HF transceiver for active mobile or space-conscious operators. Utilizing computer-aided design and automated insertion techniques, the FT-77 represents a new advance in manufacturing efficiency and reliability. Equipped for SSB and CW operation (FM optional), the FT-77 includes digital frequency display, CW wide/narrow selection, selectable agc, RIT, and a highly effective noise blanker.

A full line of accessories is available for both the FT-980 and the FT-77. For further information, contact *Yaesu Electronics Corp., PO Box 49, Paramount CA 90723.* Reader Service number 480.

SATELLITE STEREO PROCESSOR

A new satellite stereo-processing component from Channel Master now gives home TVRO users the capability of full stereo enjoyment of auxiliary audio services carried on the "birds."

The multi-mode stereo processor, model 6140, takes audio subcarrier signals from the satellite receiver and decodes them for use with an ordinary home stereo receiver system. It will also allow monaural audio subcarriers to be heard through hi-fi speakers for added enjoyment of satellite video programming.

Decoding of separate, multiplex, or matrix stereo is accomplished via front-panel, push-button selectors. Two independent tuning controls are provided for selecting the subcarrier channel desired in the range of 5.5 MHz to 8.0 MHz. A selectable i-f filter allows reception of high-fidelity programming with low distortion.

For easy tuning of favorite stations, four independently preset positions may be selected using the PROGRAM switch. Popular subcarrier frequencies have been preprogrammed at the factory on all four of these positions. The TUNE position on this switch allows the selection of alternate subcarriers.

The sleek styling of the Model 6140 Satellite Stereo Processor has been designed to match the look for the industry-acclaimed Channel Master satellite receiver. For more information, contact *Channel Master Division of Avnet, Inc., Ellenville NY 12428; (914)-647-5000.* Reader Service number 484.

ANTENNA TUNERS

Encomm, Inc., has announced two antenna tuners from Tokyo Hy-Power Labs: the HC-2000 and the HC-200.

The HC-2000 is a 2000-Watt PEP (500 Watts maximum on 1.9 MHz) HF antenna coupler with a power/swr meter and a versatile 12-position antenna switch (6 through the tuner and 6 bypass). It will tune coaxial-fed antennas, balanced-line antennas (balun included), or endfed wires. The HC-2000 is bandswitched for the 1.9-, 3.5-, 7-, 10-, 14-, 18-, 21-, 24.5-, and 28-MHz (all WARC) bands, so you don't have to experiment to find your inductor setting, plus it has 6-to-1 vernier dials on the capacitors for easy fine tuning. Scales on the dual meters include swr, 2 kW, 200 W and 20 W. Connectors are SO-239s and Johnson terminals.

The HC-200 is a combined 200-Watt HF antenna coupler with a power/swr meter and a six-position antenna switch (3 coaxial/wire positions through the tuner and 3 bypass). It will tune endfed wires, coax, or balanced-line antennas (with optional balun). The HC-200 is bandswitched for the 3.5-, 7-, 10-, 14-, 18-, 21-, 24.5-, and 28-MHz (includes new WARC) bands. Scales on the meter include swr, 20 W, and 200 W. Connectors are SO-239s and Johnson terminals.

Both antenna tuners have high quality ceramic coil forms, well-damped/well-shielded meter circuits, as well as first-class design and layout and there are no ferrite cores in the main inductor to saturate!

For more information, contact *THL Sales Department, Encomm, Inc., 2000 Ave., G Suite 800, Plano TX 75074; (214)-423-0024.* Reader Service number 481.

DB-GAIN ANTENNAS

DB-Gain Antennas of Ft. Lauderdale, Florida, has announced its new line of antenna products with the introduction of its commercial-grade dB-Gain vertical mobile antenna. Available in 450 and 220 MHz and 2, 6, 10, 15, 20, and 40 meters with a power rating of 250 Watts, these antennas were designed primarily for mobile use, but each can be used in a fixed-station application.

Each dB-Gain antenna whip and set screw is made of 17-7 stainless steel. Heavy-gauge fiberglass (.031 wall/spiral finish) coil housings provide strength and durability for extreme weather conditions. Each coil is wound with no. 16 copper, and the remaining hardware is chrome-plated brass. A standard mounting ferrule of 3/8" × 24 thread is compatible with most mobile mounts.

For additional information, contact *Tom Adams W4MTW, dB-Gain Antennas, 2308 NE 20th Avenue, Ft. Lauderdale FL 33305; (305)-566-2200.* Reader Service number 491.

DATASAVER™ AC POWER BACKUP

The Datasaver ac power backup, available in 90- and 200-Watt capacities, is a battery-powered backup unit which keeps many of the popular computer systems and instruments operating during ac power interruptions or transients. Both versions utilize a precision 0.1-percent crystal frequency standard that allows real-time power sensing and prevents video jitter that affects many computer displays.

The Datasaver provides overvoltage transient suppression and EMI noise filtering. Standard features include rechargeable sealed battery, automatic battery charger, solid-state power inverter, ac line voltage monitor and cutout switch, visual and audible alarms, and remote alarm signal for interrupt-driven computer applications. US and foreign power configurations available.

External battery jacks are provided to allow any 12-volt battery (car, motor home, boat, etc.) to become the power source for computer operation. For more information, contact Dave Dickey at *Cuesta Systems, Inc., 3440 Roberto Court, San Luis Obispo CA 93401; (805)-541-4160.* Reader Service number 478.

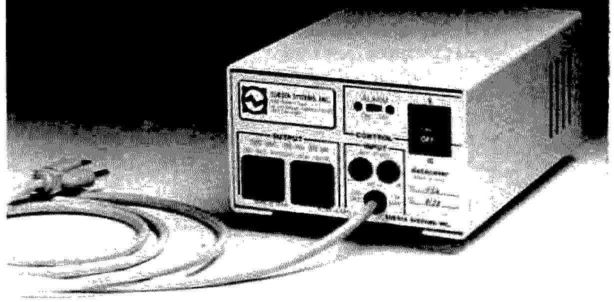
RF WATTMETER

The new Thruline® directional wattmeter expands the usual single full-scale power level of its plug-in element to seven overlapping power ranges.

Tailored for design or field service of CW and FM systems from 200 kHz to 1000 MHz and ¼ Watt to 10,000 Watts, the new precision instrument uses special elements providing seven levels instead of one covering either 1/3/10/30/100/300/1000 Watts or 10/30/100/300/1000/3000/10,000 Watts with ±5% accuracy of reading over a full 37-dB power range. The desired range is instantly selectable by a front-panel rotary switch which also includes a battery-level position. Elements are simply rotated for either forward or reflected power measurement.

Model 4410 Thruline wattmeters feature low insertion vswr of 1.05 or less, temperature compensation to maintain full-rated accuracy from 0° to 50° C, 120% over

Channel Master Model 6140 Satellite Stereo Processor.



The Datasaver™ ac power backup.

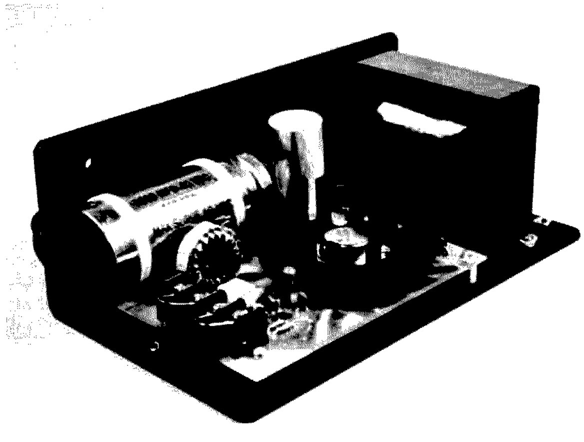
HS-700 microphone/headset from MX Products.



Jameco's JE224 power supply.

range protection regardless of the selector-switch position, and a choice of 18 common rf connectors interchangeable in the field.

For more information, contact *Bird Electronic Corporation, 30303 Aurora Road, Cleveland (Solon) OH 44139.* Reader Service number 483.

HS-700 MICROPHONE/HEADSET

MX Products has announced a new lightweight microphone/headset especially designed to complement Icom HF and VHF equipment. The HS-700 features a comfortable, lightweight headset which permits extended operation without operator fatigue and is ideal for contest-style operation. The microphone employs a miniature electret element with integral preamplifier and frequency compensation to enhance intelligibility and "punch." A wind screen is included to minimize wind and breath noise. The microphone boom is adjustable for optimum speaking distance and noise environments. Total system weight is under 4 ounces.

For more information, contact *MX Products, 1152-169th Ct. NE, Redmond WA 98052; (206)-881-0355.* Reader Service number 488.

ADJUSTABLE SWITCHING POWER SUPPLY

Jameco Electronics has added another new model to their growing family of popular power supplies. The JE224 is a high-efficiency power supply which utilizes the LH 1605, one of the latest switching regulators from National Semiconductor that provides high current output and requires only a minimum number of support components to do the job.

The JE224 is adjustable from 4 to 24 V dc and current rated 5 A at 5 V dc, 4.8 A at 6 V dc, 4.1 A at 9 V dc, 3.3 A at 12 V dc, 1.9 A at 18 V dc, and 0.5 A at 24 V dc. Outputs are regulated with over-current protection. The overall size is a very compact 7.75"L x 4.25"W x 2.75"H; and the unit weighs in at only 3.65 pounds.

For more information, contact *Jameco Electronics, 1355 Shoreway Road, Belmont CA 94002; (415)-592-8097.* Reader Service number 482.

DATA FILE MAINTENANCE PROGRAM

Russ Software has introduced Multi-File, its new data file maintenance program for the VIC-20 and Commodore 64 computers. It will work with either cassette or disk storage media, and you can store up to 100 items per file with an unlimited number of files. The VIC-20 version requires the 16K expansion in order to make full use of the program's capabilities; with 3K, files are limited to 20 or 30 items.

The data file program features search and review functions as well as delete, correct, and print data functions. The search function will look for any data on any line of the file; the more specific your input is, the more specific the search will be.

Multi-File will produce audible notification of error messages and the completion of major functions.

For additional information, contact *Russ Software Ltd., PO Box 378, Northwest Station, Chesapeake VA 23322; (804)-421-3914.* Reader Service number 485.

AWARDS

OREGON TRAIL COUNCIL CAMPOREE

On May 20-22, 1983, the Benton District, Oregon Trail Council, Boy Scouts of America, will hold its annual Camporee. This event is a weekend camping experience involving all the scout troops, most of the Cub Scout Webelos dens, and many of the Explorer Posts in the local area.

This year, the Benton District Camporee Committee has invited members of the Oregon State University Amateur Radio Club (K7UYX) to participate in the Camporee as special invited guests. The OSUARC has volunteered to set up an HF demonstration station, provide VHF communications at the camp, and assist the scouts in earning portions of their communications-related scout awards.

Operation will begin at 5:00 pm PDT, May 20, and end at 1:00 pm PDT, May 22. Frequencies are: SSB—3.940 MHz, 7.240 MHz, 14.290 MHz, 21.360 MHz, and 28.990 MHz; CW—3.590 MHz, 7.030 MHz, 14.070 MHz, 21.140 MHz, and 29.190 MHz.

For more information, contact Steve Aberle WA7PTM, 2751 NW Orchard Ave., Corvallis OR 97330.

NANTUCKET EXPEDITION

The Algonquin ARC will activate Nantucket Island, Nantucket County, Massachusetts, May 21-22. Operation will be CW, up 60 from the low end of the bands, and SSB, up 60 from the low end of the General phone bands, 80-10. We will be using the call W1BK. QSL with an SASE via PO Box 258, Marlboro MA 01752.

MT. SAINT HELENS QSO PARTY

The Clark County Amateur Radio Club, W7AIA, is pleased to announce the third annual Mount Saint Helens QSO Party which will be held May 21 and 22, 1983. This QSO party will mark the third anniversary of the cataclysmic explosion of nearby Mt. Saint Helens. This disastrous volcanic eruption took the life of Reid Blackburn KA7AMF who was an active member of this club. Reid was monitoring a USGS observation station near the base of the mountain at the time of the eruption.

Any amateur station making one contact with W7AIA during the two days from 0001 UTC May 21 through 2359 UTC May 22, 1983, will be eligible to apply for the Mt. Saint Helens Award, a beautiful certificate featuring a photograph of the mountain two years after the eruption.

Look for W7AIA on the following frequencies (plus or minus QRM): SSB—3.895, 7.230, 14.280, 21.360, 28.505; CW—3.705, 7.105, 21.105, 28.105; VHF—various Vancouver and Portland area repeaters.

To apply for the award, send log information or QSL card and $2.00 (or 8 IRCs) to: Award Manager, W7AIA, PO Box 1424, Vancouver WA 98668; (206)-693-0033. All proceeds from the award will go to the Reid Blackburn Scholarship Fund which has been established by the Clark County Amateur Radio Club, W7AIA, at Clark College in Vancouver WA.

HAM HELP

I need technical information on the Intercontinental Instruments model TPG-2 double pulse generator. I would also like information on how to reach engineers for Intercontinental, which was located in Farmingdale, Long Island.

Harold May
428 Phillipps
Hinsdale IL 60521

I am offering a $5 reward for the first offer of data which will make my hamfest purchase a functional frequency counter. The PC board contains 7 MAN readouts, 6 74144 chips, and 1 each, 5474, 7440, 7490, 7475, and 7447. There is no clock or input processor. All letters will be answered and all materials returned.

Horace Eddy W2BU
3 N. Belmont
Oneonta NY 13820

I would like information on the positive matched amplifier model PMA-2, made by Jerrold Electronics Corporation of Philadelphia. It looks like a cable TV amplifier. I will pay for any reproduction or mailing costs.

Carl S. Peterson N6CSI
PO Box 4432
Chico CA 95927

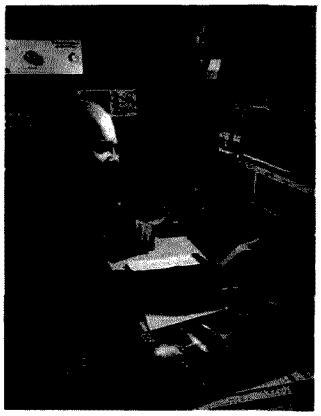
NEVER SAY DIE
editorial by Wayne Green



A KERCHUNK SUBSTITUTE?

One of the more frustrating aspects of repeaters is listening to 'em. This is such a drudge that I've noticed that few repeaters seem to ever have anyone actually monitoring. Notice that? I'll bet I've checked into several hundred repeaters in various cities, only to be met by nothing.

Perhaps it is time for us to hike up our mental skirts and make some progress toward a system which would solve a whole bunch of repeater problems all at once. Yes, *mes amis*, I have a way out of both the boredom of listening to a repeater and not being able to raise anyone on it. The problems go together, of course. If no one is listening, you really have to have a flat final if you think someone is going to answer your call, right?

Suppose we were able to come up with a relatively simple accessory to our rigs which would allow us to monitor the repeater without having to listen to all that garbage (my apologies to the garbage men). Well, of course there are already some simple systems which will work. . .for instance, a tone-encoded system, using touchtones™ to call a specific station and a decoder attached to the receiver. That's easy and should have been put in years ago.

But we're into digital circuits and microprocessors these days, so why settle for something so basic, even if it would be a godsend. Let's get what few brain cells you have left working on something a bit more sophisticated. For instance, suppose we set up a system where the repeater has a computer attached which keeps track of who is monitoring and who isn't. Until someone invents an automatic transmitter identifier system, we can still use the old touchtone pad to identify ourselves. Three tones would take care of about a thousand different stations. . .which should be enough.

Now there you go. . .I've just started to explain what I have in mind and you are already coming up with arguments. There's just no pleasing you. Well, this time I'm ahead of you. Yes, I know as well as you that half of the chaps who check in are going to eventually turn off their rigs, forgetting to check out, or perhaps drive out of range of the repeater so it won't be able to get the signal to cross them off the list of the living. No, a good system will have to check with you every so often to make sure that your rig is still on line. Feel better?

One way to do this is to have the repeater transmitter send out a coded pulse every so often which would be addressed to your particular rig and would trigger a short answer-back, thus assuring the repeater that you are still alive and well and within range. If we start using some high-speed digital addressing and identification, the whole process can take a fraction of a second.

In this way the repeater would know who is monitoring at any moment so that a caller could conceivably check to see if someone specific was on channel or even get a fast list of those monitoring so he or she could call the operator of his or her choice. Like it?

Okay, so I lied about it being simple. That just shows you can't trust everyone all the time. But it *can* be done and with current technology. It will take some experimenting. It will be worth it. . .just think of how this could change two meters for us! Lordy, I might even start checking into a couple of local repeaters if I knew that I wouldn't have to listen to every mobile coming on channel explain at length about where he is driving, where he's been, and where he's going.

Tell you what. . . I've got a $500 prize here for the first article we get on a working system to do about what I suggested. That ought to get some of you soldering-iron jockeys flinging solder and zapping ICs. Further, if you can come up with something relatively simple that does the job, I'm reasonably sure that we could set up a licensing system to get it into just about every two-meter rig being made in short order.

We're going to need such a polling system eventually to handle digital traffic, so we might as well get cracking on developing and using it now for our voice communications. And you can bet that we're going to make a big fuss over the repeater group that gets this system working first. Will it be yours?

CALLING CAPTAIN QUEEG

Old-timers will remember the captain, nervously rolling the big ball bearings in one hand, striving to relive his one great moment of success with the strawberries, no matter how inept the present situation. I'm reminded of this when I read the solemn pronouncements of old-time hams, echoed at times by true-blue youngsters who have heard the refrain but haven't yet thought about it, and it all has to do with the bottom line inescapability of the need for Morse code. We keep hearing that, dammit, when everything else stops working, hams are going to be able to throw together small transmitters and use Morse code for communications.

What a bunch of fecalberry pie! Oh, we could go along with that scenario twenty years ago, but how in the heck is even a diligent ham going to whip up a CW rig out of a carton of AM/FM stereo solid-state radios? Not that our enthusiastic ham is going to be able to find a 12-volt soldering iron to do the work anyway. Come on now, let's try to face the facts. Radios are mostly large-scale integrated circuits these days, not tubes, and these gadgets are not easily remade into anything except trash.

No, the ham who digs his way out of a cellar after a nuclear attack and dusts himself off is not going to look for 30-year-old broadcast sets to rebuild into transmitters; he's going to take the HT off his belt and see who else is around. He's going to dig into his car and start tuning his Drake to see what's going on on 75m.

Commercial radio communications these days is mostly via high-speed digital circuits. Even the high-speed Morse code we are hearing on our ham bands is generated and read by digital circuits, not the operators. Morse code, with its throughput of around ten words per minute and its requirement of two experienced operators *who are devoting 100% concentration* to the job of sending and receiving, is probably the worst possible system we can think of for using radio. Voice is somewhat better since it does not require a lot of training on the part of the operator. Setting up our communications so only we hams are able to use it smacks a good deal of featherbedding, doesn't it?

Since amateur radio has been kept so firmly about fifty years behind the rest of the communications world, about all we can really offer right now in the way of emergency communications message-handling is voice. That's about three or four times as fast as the code, but still medieval when compared to digital communications which start at around 100 words per minute these days and easily go into the thousands of words per minute.

One rig passing traffic at 1,000 words per minute (about 1,200 baud) can do the work of two hundred trained hams using two hundred rigs and CW on one hundred channels. Now tell me about the ham who is going to build a little Morse code rig and get on the air. With some experimentation we can get our rigs to work at 9,600 baud, which gives us about 8,500 words per minute. Think of 850 sweating hams. . .no, make that 1,700, because we need one on each end. . .all trying to keep up with one little box with a couple ICs in it.

How much power will we save by not having to run 1,700 rigs to handle that traffic? Think of the hamburgers and Cokes! The support of this army of dedicated hams would be monumental. Think of the laundry bills! No, it is getting time to think in terms of automation, as abhorrent as that may be to the dedicated key-banger.

When the first radioteletype experimenting began to appear on the ham bands back in 1948, a shiver of panic went through the

D'Arsonval Dossier

How these meters work and how to make them work for you is no mystery. Discover the inner machinations of the D'Arsonval movement for yourself.

This article covers the basic aspects of the panel meters most frequently used by amateurs. These meters indicate voltage and current. The article will not address itself to alternating-current meters and meters combined with electronic circuits that measure values such as FM frequency deviation, resistance, signal strength, and the like. However, a little knowledge of how the simple voltage- and current-measuring devices work may turn your junk box or your next flea-market visit into something very profitable.

Panel meters are made in a large variety of ranges, and when the desired range is not available, it is possible to adapt what is on hand to provide the necessary service. Voltmeters can be bought with ranges from millivolts to kilovolts and ammeters from microamperes to a hundred Amperes. However, by judicious buying at auctions and flea markets, low-current meters (typically, 0-1 milliampere) can be purchased that can be adapted to a wide range of currents and voltages. Read on!

Flea-market meters come in all shapes, sizes, and ranges. Some really large units are frequently seen. Six- and 10-inch sizes make great bench meters; how about an oversize S-meter for your next QRP rig? It may take a bit of patience, but even matching meters can be found if you keep your eye out for them. There are thousands of low-price, high-quality meters like the Weston 301 type available in junk boxes and flea markets.

How They Work

Meters measure current even when they are actually indicating voltage. Their needle deflection is nominally proportional to the flow of current through them. In the case of meters using D'Arsonval moving coil movements, the meter deflection is strictly proportional to the current through them. This is the most popular type of meter and will be the type primarily discussed in this article.

The only other type of meter that is normally seen by amateurs is the iron-vane type. This type is used frequently for ac measurements. It does not deflect strictly proportionally with current through its coil. Its major claim to fame (for amateur use) is its low cost. Unlike the D'Arsonval type, the current in an iron-vane meter flows through a fixed rather than a moving coil. The common, low-cost type is generally plagued with calibration problems caused by magnetic material (e.g., iron or steel) in its vicinity. D'Arsonval move-

ments are relatively but not entirely free of this sort of problem.

Meters deflect when current passes through them because the current creates a magnetic field that opposes a permanent magnetic field built into the meter. The vane in an iron-vane meter is a permanent magnet and is attached to the indicator needle. The metered current flows in a fixed coil that is wound around (but not on) the vane. The field created by the current in the coil opposes that of the vane, and the vane moves until force from its field balances the force from the field of the coil.

Flea marketeer with his meter display. Excellent sources of meters of all descriptions, flea markets and auctions offer the lowest prices. In most cases, meters work properly or do not work at all. Flea-market and auction prices are generally low enough to risk as-it-is purchasing. However, most sellers will honor your request for your money back.

D'Arsonval meters have moving coils that rotate within a permanent magnetic field. In this configuration, the fields can be properly arranged to cause the needle (attached to the rotating coil) to move in a manner that is strictly proportional to the current flowing in the coil. The proportionality of the D'Arsonval meter allows its scale to be divided into equal divisions for equal changes in current throughout its scale. The typical iron-vane meter provides more motion for a given current change at the low end of its scale than at the top end. The scale at the top end of a typical iron-vane meter is crowded and difficult to read.

Meter Resistance

The flow of current through a meter obeys Ohm's Law. The meter itself has resistance and, therefore, the current through it will be proportional to the voltage across it—see Fig. 1(a). If resistance is added in series with a meter—see Fig. 1(b), more voltage will be required to cause the original amount of meter current to flow. It will be shown later that this is the way to turn a sensitive current meter into a voltmeter. If a resistance is added in parallel with the meter—see Fig. 1(c), the input voltage still occurs across the meter, but a portion of the input current is bypassed (or shunted) through the parallel resistance. The parallel resistance is known as a shunt. This is the method for turning a sensitive current meter into a less sensitive (or higher) current meter.

If meters are to be modified with series or parallel resistance, it is obvious that the resistance of the meter must be known. Examination of meter characteristics, as given in manufacturers' catalogs, gives us the ranges shown in Table 1.

Full Scale Currant	Resistance (Typical)
100 microamps	1000-2000 Ohms
200 microamps	400-1000 Ohms
500 microamps	100-200 Ohms
1 milliamp	40-60 Ohms
3 milliamps	20-40 Ohms
5 milliamps	10-20 Ohms

Table 1. Typical sensitive current meter resistances (D'Arsonval type).

In no case should an ohmmeter be connected across a sensitive meter to determine its resistance. The current from the ohmmeter will overrange the meter and may destroy it. A convenient and safe method of determining the resistance of a meter is shown in Fig. 2. It consists of causing full-scale current to flow in the meter and then adding a variable resistance (shunt) across the meter and adjusting it until the meter reads half-scale. If the series resistance (R_{SE}) is much higher than the meter resis-

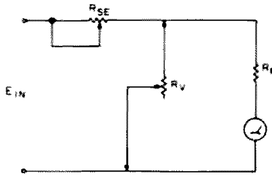

Fig. 2. Determining meter resistance. Set E_{IN} and/or R_{SE} for full scale with R_V disconnected. (R_{SE} should be at least 100 × R_M.) Connect R_V and adjust it until the meter reads one-half scale. Disconnect R_V and measure its resistance with an ohmmeter. R_V will equal R_M.

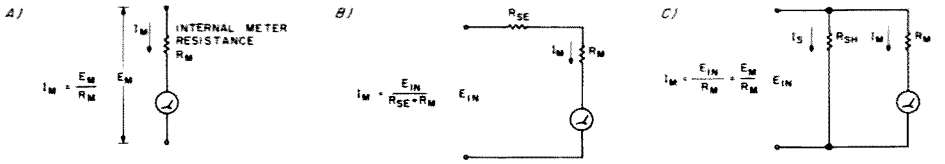

Fig. 1. Basic meter circuits. (a) Electrical characteristics of meter alone. (b) The meter with resistors in series. (c) The meter with resistance (R_{SH}) shunting current around it.

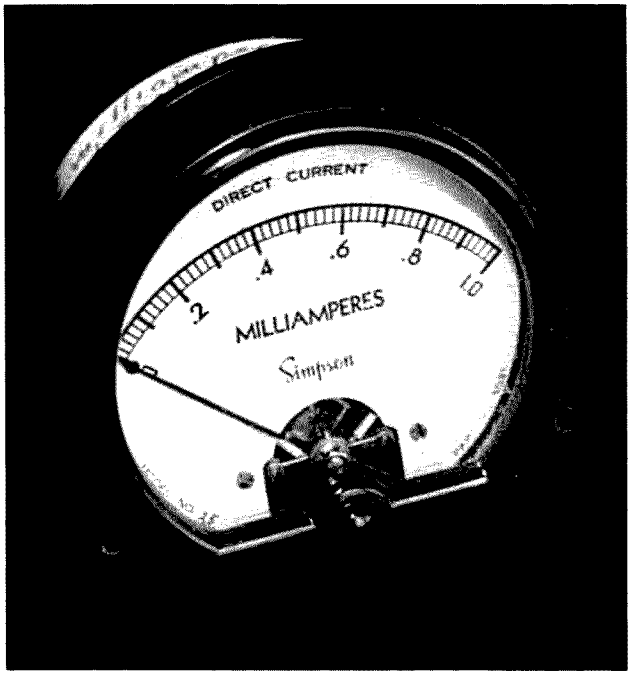

A typical D'Arsonval meter movement is shown above. Note the even (linear) scale. All of the divisions are the same size. This type of meter is the most used by amateurs. The ordinary variety balances the force resulting from a fixed magnet and a moving current coil against a pair of hair springs. Recently, a new type using taut-band springs has been introduced. Both types operate similarly and have linear needle motion with respect to current.

tance (use Table 1 as a guide), the total current will not vary significantly when the variable resistance is added. It can be shown that when the variable resistance is adjusted for half-scale current, the meter resistance is equal to the external shunting resistance. The external resistance can then be disconnected and (safely) measured with an ohmmeter.

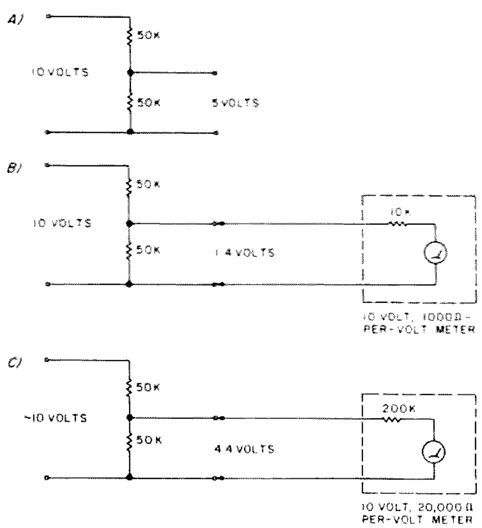

Fig. 3. Voltmeter circuit loading. (a) High-impedance voltage divider. (b) The result of a voltmeter loading down the circuit in 3(a). (c) Using a meter with higher internal resistance gives more accurate results.

Meter Resistance Problems

In the case of voltmeters, the resistance of the meter and its series resistors must be high with respect to the resistance of the circuit being measured. If it is not, the voltmeter will load down the circuit and the voltage measurement will be low. This is illustrated in Fig. 3. Note in Fig. 3(a) that the real divider voltage is five volts and that a 1,000-Ohms-per-volt meter, see Fig. 3(b), loads the circuit down to 1.4 volts (72% low). Even a 20,000-Ohms-per-volt meter as shown in Fig. 3(c) loads the circuit down to 4.4 volts (12% low). If an 11-megohm vacuum-tube voltmeter were used, the indicated voltage would be essentially correct, at about 4.99 volts (0.2% low). The moral here is very clear: Use the highest resistance voltmeter that you can if you want to avoid loading down the circuit being measured.

Voltmeters are rated for their resistance in Ohms-per-volt. Simply, this means that a 10-volt, 20,000-Ohms-per-volt meter will have a resistance of $10 \times 20{,}000 = 200{,}000$ Ohms. In a multi-range voltmeter, the resistance of the meter accordingly increases with the voltage range in use. Electronic voltmeters are frequently an exception to the foregoing statement. They have a fixed input resistance (frequently 11 megohms) regardless of the range they are set to.

However, do not write off the lowly 1,000-Ohms-per-volt meter (made from a 0-1 mA meter). In this day of solid state, circuit resistances (with certain exceptions such as FET circuits) tend to be quite low and quite tolerant of low-resistance voltmeters. Additionally, one should examine one's needs carefully. The 1,000-Ohms-per-volt meter is rugged, inexpensive, and is just the thing for an occasional check of power supply and battery voltages. If general servicing of tube and solid-state circuits is to be done, nothing short of a voltmeter with megohms of input resistance should be considered.

For the most part, insertion of a meter for current measurements does not cause significant circuit change. Milliammeters have resistances of less than 100 Ohms, which is small with respect to resistances (impedances) they are connected in series with. Consideration should be exercised with meters in the microampere ranges. A sensitive microammeter may have over 1,000 Ohms resistance and could add significant resistance to the circuit being measured.

Making Voltmeters from Milliammeters/Microammeters

Voltmeters with convenient scales can be made by adding series resistance to a milliammeter or microammeter, most often to a 0-1 milliammeter or more sensitive meter. It is most convenient to choose a meter range whose scale can be multiplied by a factor of 10, 100, and so on, to give the desired voltmeter scale. For example, say you want a 1,000-volt, full-scale meter. If a 0-1-milliamp meter is

Meter Range	Ohms to Produce One Volt Full Scale (Ohms-per-Volt)
0-1 mA	1,000
0-500 μa	2,000
0-200 μa	5,000
0-100 μa	10,000
0-50 μa	20,000

Table 2. Voltmeter series resistance ratings.

used, the scale is multiplied by 1,000 and a label can be added to the meter face saying: "1,000 volts." Half-scale (0.5 mA) will be 500 volts. Similarly, a 100-microamp meter could be used with a × 10 multiplier.

For most amateur purposes, the series resistors can be 5% tolerance and the meter resistance can be neglected. Table 2 can be used to select the series resistance required to obtain a one-volt full-scale meter from various basic meter movements. If the series resistance is increased by a factor, the full-scale reading will be increased by the same factor. Typically, if 1,000 Ohms is required for one-volt full scale, 2,000 Ohms will result in two-volts full scale and 10,000 Ohms will give 10 volts. The series resistance rating for a basic meter may be calculated by dividing one by the basic full-scale meter reading. Typically, a 0-3 milliammeter would require 1 ÷ 0.003 = 333 Ohms-per-volt.

The accuracy of a meter with added series resistance depends on the meter accuracy, the series resistor accuracy, and the meter's internal resistance. The latter effect is generally small for the accuracies needed by the amateur. For a 1-volt, 1,000-Ohms-per-volt meter that uses a basic 0-1 milliammeter with 50-Ohms internal resistance, the total series resistance is 1050 Ohms (assuming a 1000-Ohm external series resistor). Ohm's Law tells us that 1.05 volts will be required for a full-scale reading. This is a 5% error and could be corrected by using a 950-Ohm series resistor. For high voltage ranges, the error becomes proportionately less.

If you have a means of accurate calibration at hand, the series resistance can be trimmed to eliminate essentially all of the error at *one* scale reading. The remaining error will be the meter's inherent inaccuracy. For the best possible accuracy, the error at various scale values has to be plotted using a highly accurate calibration standard. This discussion of accuracy is included only to satisfy the reader who has special accuracy requirements.

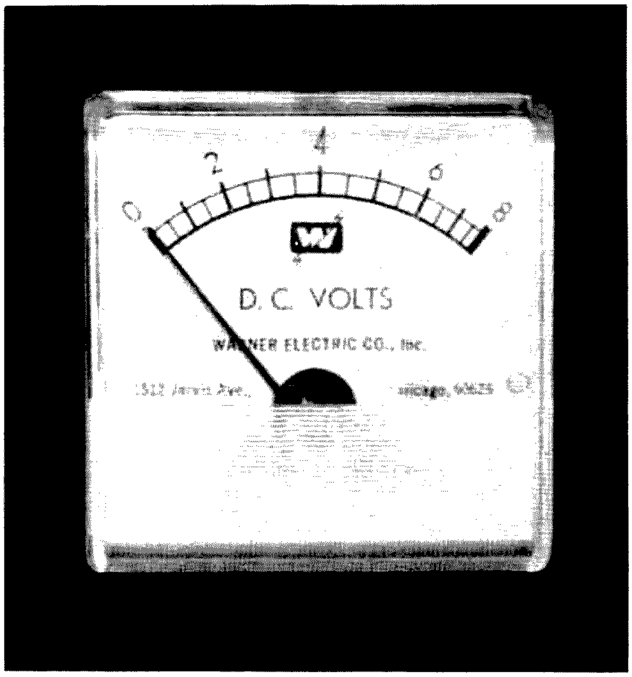
The average amateur can use series resistance values calculated from the basic values in Table 2. He can assume that his accuracy will be roughly that of the series resistance tolerance plus the meter's tolerance, i.e., on the order of ±10%, if ±5% series resistors are used.

Shunting to Obtain Higher Current Ranges

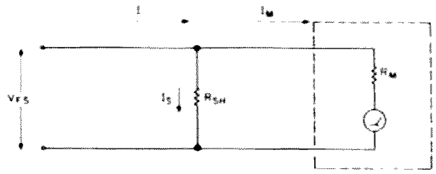
Shunting is just a bit more difficult than adding series resistances to obtain different voltage ranges. First, the resistance of the shunt must be calculated. Then, the shunt resistor must be obtained. Most often, the shunt resistor will have to be wound or otherwise fashioned. This is because the resistance values turn out to be quite low and most often of non-standard value.

The shunt resistance in parallel with the meter resistance must result in a voltage across the meter that will produce full-scale deflection for the desired full-scale current. This voltage is calculated using Ohm's Law as follows: $V_{FS} = I_{M(FS)} \times R_M$. (Here, V_{FS} is the voltage across the meter at full scale, $I_{M(FS)}$ is the basic meter's full-scale current, and R_M is the meter resistance (see Fig. 4). The method of determining R_M was previously discussed. It should be noted that meter resistances can sometimes be found by referring to catalog descriptions. By using the parallel resistance expression and Ohm's Law, it can be shown that the shunt resistance is: $R_S = R_M(V_{FS}/I_{FS})/(R_M - V_{FS}/I_{FS})$, where I_{FS} is the desired full-scale current and R_S is the corresponding value of resistance needed to shunt the meter.

For example, the shunt required to make a 10-milliamp meter from a 50-Ohm, 1-milliamp meter is calculated as follows: $V_{FS} = .001 \times 50 = 0.05$ volts, and $R_S = (.05/.01) \times 50/50 - .05/.01) = 5.56$ Ohms.



This photo shows the face of an iron-vane-type meter. Note that it has an irregular (non-linear) scale. For the same amount of current change, less motion occurs near full scale than at the low end of the scale. In some applications this may have advantages. Most meters of this sort are made for low-cost applications or for use in ac applications. They are frequently found in automotive equipment, both in car instrument panels and in devices such as battery chargers.



a $V_{FS} = I_{M(FS)} \times R_M$, FULL SCALE VOLTAGE

b $R_{PAR} = \dfrac{R_{SH} \times R_M}{R_{SH} + R_M}$, SHUNTED METER RESISTANCE

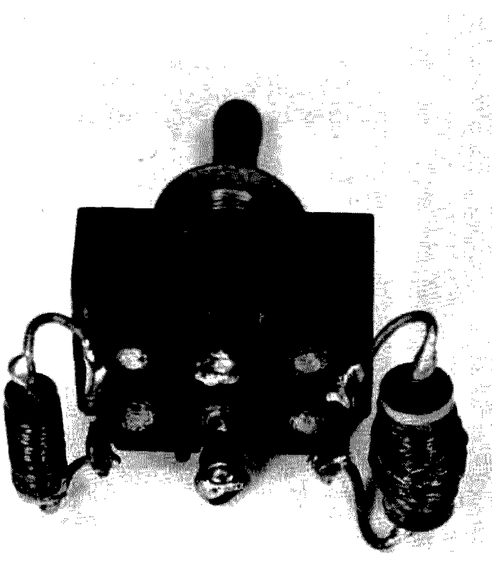
c $R_{PAR} = \dfrac{V_{FS}}{I_{FS}}$, SHUNTED METER RESISTANCE

REQUIRED FOR A DESIRED VALUE OF CURRENT AT FULL SCALE (I_{FS})

d $R_{SH} = \dfrac{R_{PAR} \times R_M}{R_M - R_{PAR}}$, SHUNT RESISTANCE

OR $R_{SH} = \dfrac{\frac{V_{FS}}{I_{FS}} \times R_M}{R_M - \frac{V_{FS}}{I_{FS}}}$

Fig. 4. Shunt value calculation.



Shunts may be wound using resistors as forms. The shunts above are those used in the 0-3, 0-30, and 0-300 milliamp meter described in the text. The resistors should be at least 100 times the resistance value of the shunt. Use a two-Watt resistor if you have room. This gives better cooling and makes construction easier.

If a 100-milliamp range were desired, the foregoing calculation would indicate that 0.505 Ohms was required. Note that in both cases the shunt resistor is in proportion to the amount of current that must bypass the meter. In the latter case, the shunt is about 1/100 of the basic meter resistance. As can be seen from these calculations, the resistances are low and (generally) non-standard.

However, shunt resistances can be constructed easily from copper wire. They also may be constructed from other less available wires such as nichrome if you have the materials available. By using the Standard Wire Tables found in the handbooks, the wire gauge and the length of this gauge wire necessary to construct a proper shunt can be determined easily. As in the case of series resistors for voltmeter applications, the shunts can be trimmed and adjusted if accurate calibration standards are available.

As in the case of voltmeters, the meter can be made truly accurate at one scale reading and must be error-noted at other readings because of the basic inaccuracies of the meter. For amateur use, this sort of accuracy is most often not necessary. Typically, in the 100-milliamp case cited above, a 0.5-Ohm, ±5% resistor will give overall accuracy on the order of ±10%. This would suffice in almost all amateur applications. A 5-Ohm, ±5% resistor would do for the 10-milliamp case.

To make low resistance shunts, choose a convenient wire size and determine what its resistance-per-unit length is. In most tables this is given in Ohms-per-thousand feet. Use the largest convenient wire size to ensure good current capacity, and try not to use very thin sizes (e.g., less then #30) to avoid variations in resistance because of stretching. Many choices may be made depending on the wire size(s) you have on hand. In the two cases calculated above, some of the choices are shown in Table 3.

	Wire Size	Ohms-per-1000 Feet	Ohms-per-Foot	Required Length
5.56 Ohms	30	105.2	0.105	52.4 ft.
5.56 Ohms	33	211.0	0.211	26.4 ft.
0.505 Ohms	28	66.17	.0662	7.63 ft.
0.505 Ohms	24	26.17	.0262	19.3 ft.

Table 3. Typical wire length for two values of resistance.

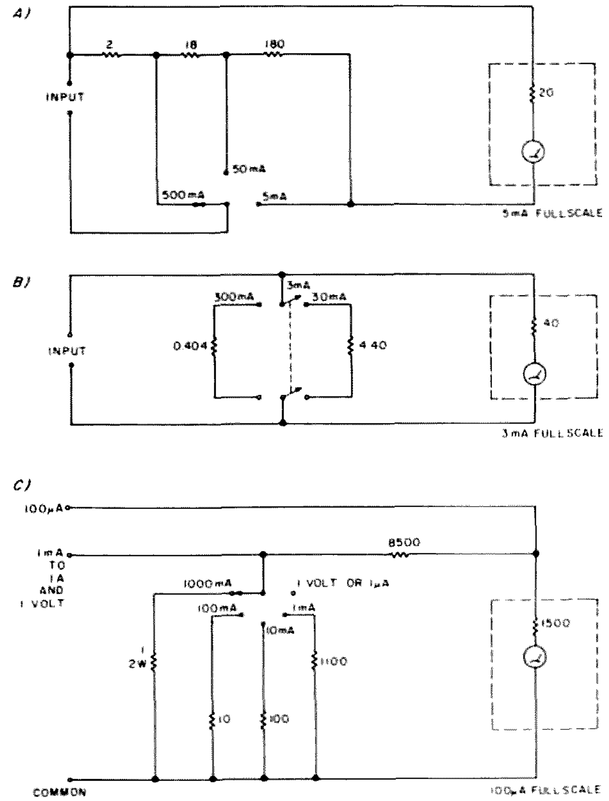


Fig. 5. (a) A multi-scaled milliammeter using an unusual series and parallel shunting scheme. (b) A multi-scaled milliammeter using standard shunting and a DPDT center-off switch. (c) A multi-scaled milliammeter/microammeter that produces less than one volt drop at full-scale current. Resistances are in Ohms.

The determination of the required wire length is made quite easily by dividing the required resistance value by the resistance of the wire in Ohms-per-foot. The latter is determined by dividing the Ohms-per-thousand-feet rating by 1000 (see Table 3 for illustrations). Some trial-and-error calculation is generally required to choose a size that results in a relatively small coil (or spool) of wire of a size you have on hand. Shunts should be wound on forms such as a relatively high-value resistor (100 times the shunt value) and should be coated with varnish or other strong coating that will prevent the turns from moving as a result of on/off current change.

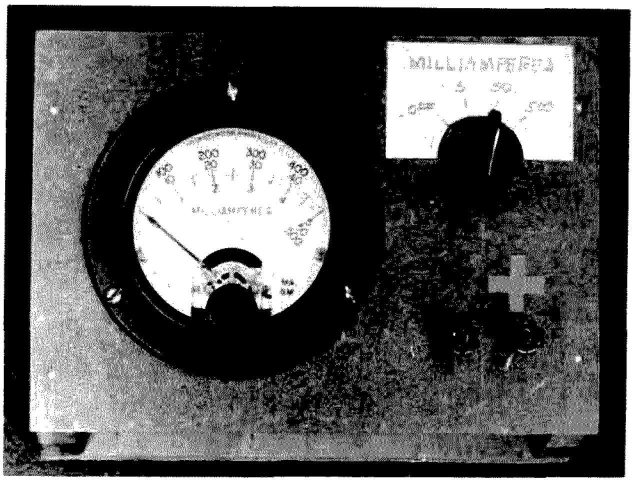
Shunts should be located as close to the meter ter-

minals as convenient. However, low-current shunts can be located "in-circuit" with their meters in remote positions. In these cases, the circuit resistance to and from the meter must be low with respect to the meter.

If you are clever with Ohm's Law, many special cases can be developed for shunts. Fig. 5 shows a neat way of building a multi-scaled milliammeter using a 5-milliamp, 20-Ohm meter. A more conventional multi-scale approach is shown in Fig. 5(b).

Fig. 5(c) makes a lot of use of a 100-microampere, 1,500-Ohm meter. (Incidentally, these appear to be readily available from surplus houses these days.) Ranges are provided from 100 microamperes to one Ampere, and a bonus scale of one volt is provided. A drawback to this circuit in at least the one-Ampere range is the fact that the drop across the meter circuit will be one volt for full scale on all current scales except the basic 100-microamp range.

Examination of the circuit will quickly show that it is a one-volt, 10,000-Ohms-per-volt voltmeter that measures the voltage across shunts that develop one volt for full scale. Note that the one-milliampere shunt is 1100 Ohms. This, in parallel with the meter resistance, gives an input resistance of roughly 1000 Ohms. Consequently, the accuracy on this range is improved. On the other ranges, the shunt resistances are low enough to make the parallel effect of the meter circuit insignificant.



Home-built multi-scaled meters can be housed in metal or wooden cabinets. The example above is a multi-scaled milliammeter built into a Masonite™ and wood enclosure. Care should be taken to protect terminals and circuitry that may carry dangerous voltages. Further, circuitry of this sort should always be protected to avoid accidental shorts that may burn out the circuit under test or the meter itself.

Conclusion

This article has only scratched the surface of the subject of meters and their applications. However, it can serve as a basic reference for the many newcomers to our hobby.

The kind assistance of Robert Foley and Julius Hoffer W1DL is acknowledged. They reviewed the draft of this article and made valuable suggestions.■

Save Money on Used Meters

Does it work or doesn't it? This simple tester spots real hamfest bargains.

Keats A. Pullen, Jr. W3QOM
2807 Jerusalem Road
Kingsville MD 21087

The prices seen on meters at hamfests these days as compared to list prices can easily make one's mouth water if one is interested in observing the operating characteristics of either transmitters or test gear. Nonetheless, one may shy away from purchases because an inoperative meter may not be worth anything at all.

Fortunately, there are several useful solutions to this problem, each of which has its particular advantages. Probably the more important meters to test, and among the more expensive, are microammeters and millivoltmeters. They are also among the more delicate. The techniques for testing these meters can be applied to many of the other types if changes noted later are taken.

The simplest test, although not necessarily the best, is to compare the pointer damping (sluggishness) with and without a short across the meter terminals. Since use of every bit of space available for the moving coil is essential with meters having full-scale ranges of 100 microamperes or less, the customary aluminum damping frame used for the moving coil in less sensitive meters is often not used. As a result, the movement turns easily when the body of the meter is rotated gently.

When the terminals are shorted on one of these meters, however, the movement of the coil typically becomes sluggish. One can then use a clip lead or a small screwdriver for making a continuity test. A substantial change in the damping characteristics will be noted with or without the short in place. And the test can in no way damage the meter under test.

In making this test, one holds the meter in one hand and rotates the case quickly along the coil axis. Inertia will cause the movement to lag behind the case, and the mass and spring will act like a resonant circuit. The amount of damping in the motion of the pointer will be a function of the effect of the coil frame and the external short.

The best technique I have found for testing current meters is by the use of a constant-current source like the LM-334. This source is used with a control resistance of magnitude (68/I) where the current, I, is in milliamperes, between the calibration terminals. A nine-volt transistor battery, a push-button, a small box, and test leads are required to complete the unit. The normal current range is from one microampere to ten milliamperes, for resistances from 68,000 Ohms to 6.8 Ohms.

The number of current steps you select will depend on your application. The unit I use has test currents of 1, 10, 100, 1000, and 10,000 microamperes. Better testing can be obtained through either ratios of 1:3:10 or 1:2:5:10. These test points will provide a more sensitive test for friction due to filings, etc.

In using this device, start at minimum current and observe the pointer as you change ranges. A rough check of calibration is available (±10 percent) and, more importantly, you will be able to detect mechanical problems as noted above. With a device like this, you can very quickly decide if a meter is suitable for your application.

This unit can also be used to test voltmeters up to its nine-volt maximum. Most voltmeters will deflect at least a little with nine volts, so you simply connect the current source and step the current up until the pointer moves. The nominal voltage will be between eight and nine volts.

If you are looking for either higher-current or higher-voltage test units, then a different approach is indicated. For higher current, the use of a D-cell, a push-button, and a few resistors (or perhaps a rheostat) should suffice. A current-limiting resistance set for approximately the maximum current is desirable, with the rheostat providing varying current values. The approximate maximum is first set, the unit connected to the meter, and the test initiated. The required minimum resistance is approximately 1.5/I, where I is the maximum current in Amperes and the 1.5 is the voltage from the D-cell used for the test.

For higher-voltage voltmeters, either a high-voltage battery or several nine-volt batteries may be used. Since, however, these meters are often designed for external multipliers, first tests should be made with the constant-current source. Up to a meter range of eight volts, the deflection will be current controlled; above, the voltage limitation takes over.

As is explained in my book, *Design of Transistor Circuits, with Experiments*, published by Sams, there are many ways of devising special test circuits that can help you both to understand how some of your circuits and devices are operating and to test them conveniently. ■

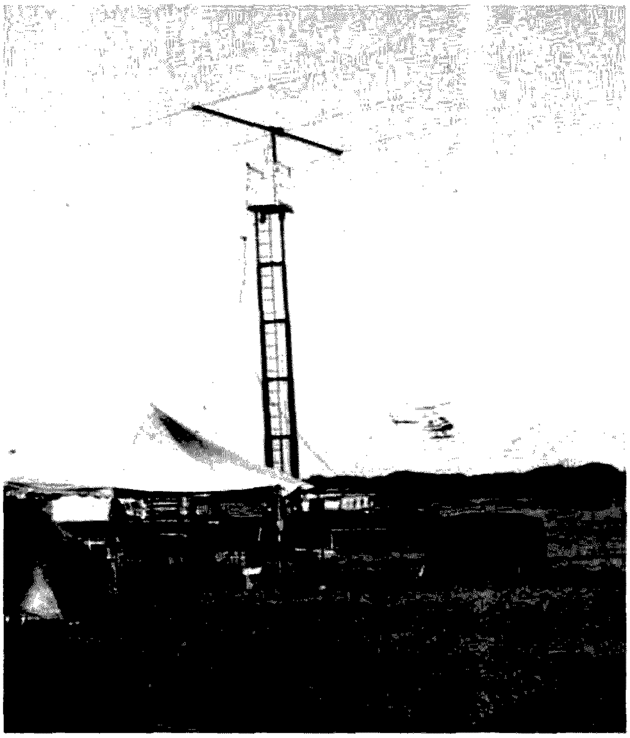
Live, From Across America—It's Field Day!

The Corpus Christi Amateur Radio Club had helicopter TV coverage of its activities. Club member WB4EMI unveils the secret behind their success.

During Field Day, most amateur groups and clubs are scurrying around looking for media coverage for their local Field-Day outing. For the Corpus Christi Amateur Radio Club in Corpus Christi, Texas, things are a little different. The news media literally brings the coverage to them. The amateur community is highly respected by many government and media organizations due to its past performances, and any request by the amateur group is seriously considered. This consideration is especially true of KRIS-TV, channel 6.

Photos by KA5GIA



The KRIS-TV helicopter while shooting live Field-Day coverage.

The founder of KRIS-TV, T. F. Smith, Sr. W5VA, was a pioneer in radio broadcasting and amateur radio in Texas. KRIS-TV still has the .34-.94 repeater on its tower that was installed many years ago. The present owner, T. F. Smith, Jr., though not an amateur, has kept the tradition of amateur radio alive at channel 6. The most outstanding example of this cooperation was use of the station's Jet Ranger helicopter for live coverage during this year's Field Day.

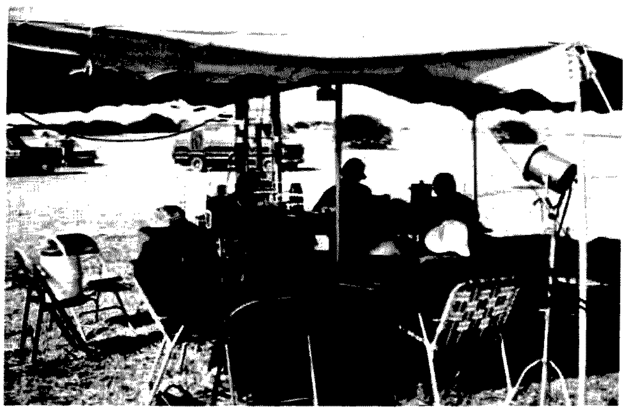
The station has a five-o'clock local newscast in addition to its more formal 6:00 pm newscast. At five on the Friday before Field Day, Bob Douglas W5GEL was interviewed for two minutes on the subject of radio and the upcoming Field Day. At the end of the interview, the newscaster announced that the Field-Day event was open to the public and that the station would do two live remotes from the site including one from Sky 6, the station's helicopter. Since the use of news helicopters is relatively new in this market, great interest is generated by the appearance of the copter.

Sky 6 arrived at about 5:00 pm and landed near the Field-Day site, with about a hundred people there to greet it. The station's mini-cam van had arrived earlier along with a reporter who spent an hour getting all the details correct. The newscast opened with a "bump shot" from the helicopter, promoting the story, followed by national and local lead stories. Then at 6:06 pm, the anchorman at the station introduced the story with special-effects shots of the site live from the helicopter. The next shot was of the same area from ground cameras, which then panned to the reporter and covered a 2½-minute interview with K5OG, the club president. Coverage was repeated at 10:00 pm without the helicopter.

So, for this Field Day, KRIS-TV provided more than 8 minutes of coverage, some of it from a very expensive helicopter.

KIII, channel 3, had sent a videotape crew and reporter during the setup, and they carried a 2½-minute package at 6:00 pm and a 90-second package at 10:00 pm.

The main Field-Day tent getting Sky 6 coverage.



Inside the tent. Note photoflood light for live TV coverage.

One needs to stop and think about what 12 minutes of air time really means in terms of publicity for a club. The combined ratings of both stations are in excess of 60% of the homes with television. In other words, more than 60,000 people saw some coverage of Field Day in Corpus Christi.

Some of the equipment on the helicopter may be of interest to amateurs. Sky 6 is a Bell Jet Ranger with an air speed of 120 mph and a range of 300 miles; it carries a payload of 900 pounds of people and equipment. The aircraft costs about $350,000 and the television equipment adds about $75,000 more. The operating cost to the station is approximately $450 per hour.

In addition to the usual navigation and communication equipment, the helicopter is equipped with a 12-Watt, 2-GHz microwave that is selectable to one of 15 channels in the 2-GHz band. The microwave transmits full-color video and two separate audio channels. One channel is for the program audio and the second is for the cameraman to tell the station director what he is planning to shoot, etc. This one is one way and feeds into the director's headset.

The antenna is a circular polarized beam with either 9-dB gain or 17-dB gain. It can be hand-held or mounted on the aircraft frame. It is usually hand-held in the 17-dB-gain position. An omnidirectional antenna is difficult to use in a coastal area due to multi-path problems over water. The directional antenna eliminated most of these problems.

The antenna is aimed visually from the aircraft to the receiving antenna for local operation and "talked on target" by the control room for longer shots out to 125 miles. The beamwidth of the antenna is such that once on target it is relatively easy to keep it there. Control room people watch the agc of the receiver and talk to the antenna operator, keeping him "peaked up." While this system may sound crude by some standards, it is very effective and removes multi-path problems. The receiving antenna consists of four 90-degree horn antennas which select which quadrant the copter is operating in and require no further attention.

In addition to the microwave equipment, there is a 10-Watt business-band FM radio for antenna positioning, time cues, etc. The three TV crew members listen to this in one half of a dual-headset system with program audio in the other ear. For safety reasons, the pilot can hear only aircraft radio traffic. During news operations with other helicopters in the area, all pilots use a second aircraft frequency to coordinate who will be over the news area. Stations take turns shooting the story then fly to a safe area while the competition takes its turn.

Another feature of Sky 6 is the inclusion of ham-radio equipment on board. Since 75% of the members of the engineering department of KRIS-TV are licensed amateurs and two of the four crew members are always engineers, there is always at least one ham on board. The helicopter has fixed antennas for 2 meters and 460 business-band radios, and there is a 444-MHz antenna available that can be mounted in a few seconds. The equipment is a Kenwood 2500 or an Icom IC-2AT and IC-4AT. One Watt is more than enough power from an aircraft. The rubber-ducky antennas work from the aircraft; however, we elected to use external antennas to avoid possible interference problems.

The full potential of this equipment has not been tested yet. It has, however, been used to assist amateurs on the ground during a parade. The amateur equipment is aboard every flight of Sky 6, and if it is ever needed, the hams of Corpus Christi will have a relay station in the sky.

I once heard a local NOAA weather meteorologist comment, "I just wouldn't want to have a hurricane without the hams here." There is a two-meter radio available at the weather service, and the local civil defense has operators ready almost at a moment's notice to assign to the weather center. One thing that impressed the weather service was the preparation of the hams assigned there during the last hurricane. This crew arrived with radio equipment, spare radio equipment, antennas, food, sleeping bags, emergency power, and fuel. They came to do a job and were prepared to hold out until that job was finished.

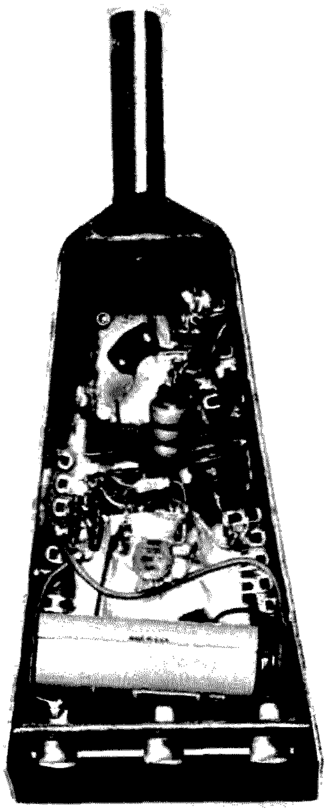
This is the kind of image that amateur radio needs in every community, and the way to get this image is to do a job and make sure the media know who you are and what you did. Tell them what you are going to do while you are preparing, as in a Field Day. Then tell them while you are doing it and make sure they get it right.

The Corpus Christi Amateur Radio Club enjoys a special relationship with members of the news media. This relationship is the result of hard work in times of stress and of knowing how the news media operate. Knowing the interworking of any news operation is the key to getting your story on the air. Some people call this press manipulation, others call it press relations—what term you use depends upon which side of the fence you are sitting on, but the result is the same.■

Construct the Cyclops Dip Meter

W4ATE's unique single-coil design captured an Honorable Mention in 73's Home-Brew II Contest. Now you can build this award-winning circuit for yourself.

Gene Brizendine W4ATE
600 Hummingbird Drive SE
Huntsville AL 35803



Component layout.

The dip meter is clearly one of the most versatile tools for anyone involved with antenna systems or rf-related equipment. Its myriad uses range from troubleshooting tuned rf circuits to locating power lines concealed inside a building wall.

The most evident shortcoming of present-day dippers is the inconvenience of constantly changing and storing a half-dozen plug-in coils. Especially frustrating is the experience of attempting to pinpoint the frequency of a resonant circuit which falls at either end of the dial range. When another coil is plugged in, the meter current requires readjustment, and one often wonders whether the new dip obtained is the same one as read with the previous coil.

Dip-Meter History

These problems have been endured for years and have been attacked from many directions. One commercial design utilized a coil of flexible wire which was reeled from one nonconducting coil form onto a metal shorting form as the dip meter was tuned through its continuous range. The product was cosmetically attractive, but not entirely practical, and appeared only briefly on the market.

I at one time built a prototype dip meter with all coils

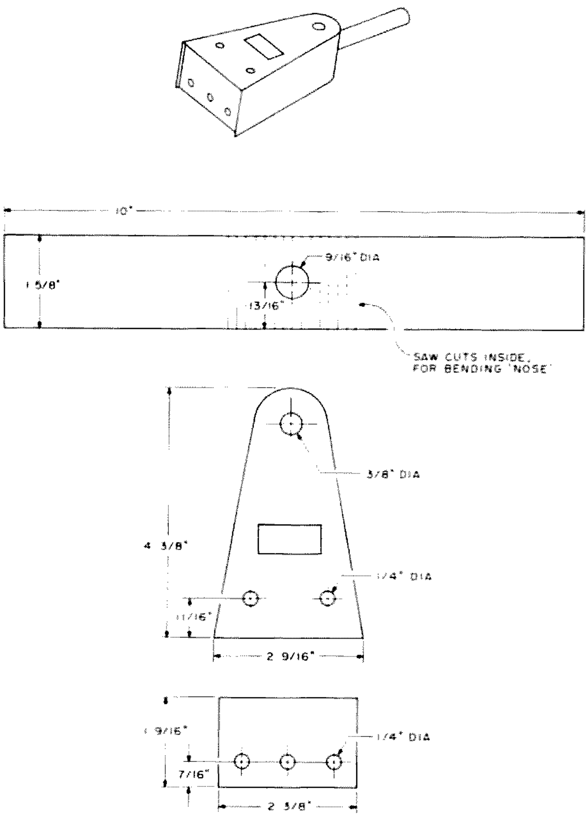


Fig. 1. Meter-case construction for the one-coil dip meter. Material is glass epoxy double-clad PC board.

Completed meter.

mounted on a turret and enclosed within a non-shielding case. The unit performed well, but was too bulky to reach tuned circuits located within high-density packages. Other wide tuning range tanks are possible, but may involve mechanical complexes which simultaneously tune a variable capacitor and move a ferrous coil slug. In the dip-meter application, the proximity of the slug would disturb the tuning of the measured tank; also, the arrangement becomes too large.

The Single-Coil Concept

Most "new" devices are the happy result of divorcing and remarrying existing arts into combinations not previously joined. So, a wide-range tank used in a previous design[1] was recalled and set up in prototype for study. The type of variable capacitor which utilizes plastic sheets between the plates provides maximum capacity per cubic centimeter. However, in this application, rf heating of the dielectric occurs, resulting in unacceptable frequency drift. Suitable compact air-dielectric units are listed in the parts data.

To provide the widest tuning range, a capacitor with the highest maximum-to-minimum tuning capacity ratio is required. For this reason, select one with the widest gap when adjusted to the wide-open plate setting. All parallel padders must be removed completely. To further ensure the widest tuning range, the lightest loading of the tank by the active device is necessary, which also points to the use of an FET. Reduction of loading by tapping down on the coil usually introduces false dips; therefore, a low-value gate coupling capacitor is used instead. The inductance of the coil between the source tap and ground resonates well above the design coverage and therefore causes no erroneous indications. The coil is shaped with a high length-to-diameter ratio to allow probing components located in close quarters.

The Circuit

The wide-range tank was joined to the vigorous Hartley oscillator in a simple one-

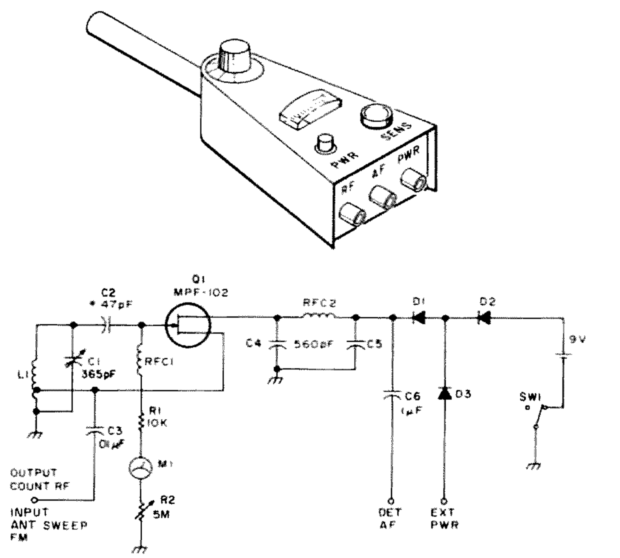

*Fig. 2. Circuit schematic and details of control mounting. *Polystyrene or silver mica. See Parts List.*

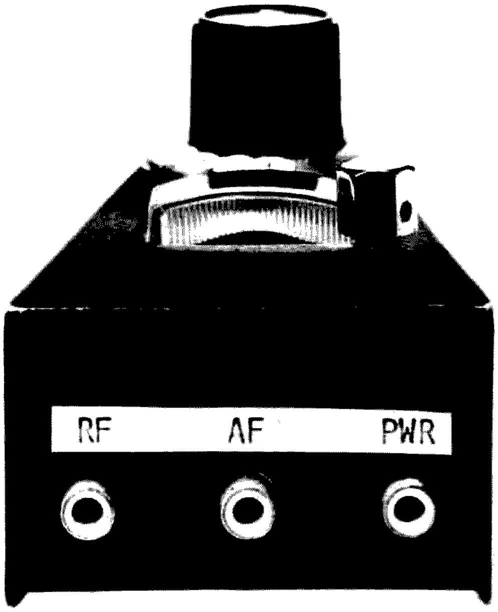

End view.

ring ceremony. The most critical items for minimizing minor spurious dips are the two rf chokes. The small 3-pi winding type has been found to be a good choice. Chokes with metallic cores are not recommended. To a minor degree, the gate resistor may cause ripples. Values between 3 and 10k Ohms are suitable. The gate-current potentiometer value of 5 megohms was chosen so that conditions of regeneration or near-oscillation may be easily controlled for use in the detector mode.

Construction

The case used for the one-coil dip meter is not critical. The LMB type 425 or Econobox type CU-124 enclosures are suitable and will permit a larger dial. The case I used was formed of glass epoxy printed circuit board with the copper stripped from the outside surfaces while applying heat. Copper is also removed from inside the "nose" area, which is also sawed halfway through for forming the curved portion. The forming should be done outdoors to avoid breathing fumes generated by heating the material. Apply heat from a propane torch and bend the curved portion around a suitable piece of pipe. The heated board should be held in the desired shape by a C-clamp and allowed to cool for 5 minutes.

The meter and tuning capacitor are epoxied in place for simplicity and to avoid screw heads showing on the finished exterior.

Wind the tank coil onto a suitable form such as the shank of a drill bit, after wrapping the bit with waxed paper. Coat the coil with epoxy cement and allow it to harden overnight. If carefully slid off, the coil will remain in one rigid unit. The coil protector may be a plastic pill box, dime coin holder, or the container in which semiconductors are shipped. This item is epoxied in a hole cut in the nose section of the dipper case and allowed to harden.

The dial (Radio Shack 274-391) may be calibrated using a receiver. Decal labels may be applied. Page numbers punched from a magazine were used in my dipper.

All small components are soldered to three 5-lug terminal strips which are located inside the case sides. Wiring requires two precautions: Locate the FET as near the tank terminals as possible and wire the rf chokes with the shortest leads possible to the FET. This care will minimize minor unwanted dips.

Additional Features

Three I/O ports are provided at the front panel. From left to right, these are labeled RF, AF, and PWR. The rf phono jack output may be used to drive a frequency counter, a mixer, or other equipment.

Conversely, an antenna may be fed in at this point or a sawtooth waveform may be applied to provide a wide-range, swept test signal from the dipper.

The af port may be used to monitor AM signals or to detect ripple on carriers.

The power jack permits the use of an external power source. Isolation diodes prevent conflict between battery and the ac power source and also protect against damage from accidentally applying incorrect polarities. Any of these features may be omitted if only a basic dip meter is desired.

Operation

With power on, set the dial to the highest frequency and adjust the meter indication to about 3/4 of full scale using the potentiometer. No further adjustment of the meter level will be required. It is normal for the meter indication to decrease as the frequency is decreased (due to the low value of the gate-coupling capacitor). This drop is of no consequence because generous dips are available across the full frequency range. Small meter fluctuations across the range also are not of significance.

Granted, tuning is sharp in the high-frequency portion of the coverage. But the chief usefulness of a dip meter is not in precise frequency measurement but in the rapid scanning of a wide range of frequencies.

Now it is a pleasure to quickly scan the 3.9-to-21-MHz range in one uninterrupted swing without all those loose coils, meter adjustments, and recoupling! ■

Be the First on Your Block with a 2-Meter Dipole

A few safety pins, some wire, and a little rod stock will make a portable antenna perfect for the traveling ham.

Paul L. Schmidt W9HD
PO Box 105
Bloomfield IN 47424

A dipole on two meters! You've got to be kidding. That is often the response I get when I explain that I use a dipole antenna on two meters.

Then I ask what kind of element excites a yagi beam. It is called the driven element, but it is a dipole, nevertheless. The number of dipoles on two meters is considerable.

Dipole antennas work fine on two. I have had one for at least five years, mounted in the vertical plane some two-thirds of the way up my fifty-foot TV mast. My dipole is made from two pieces of rod stock fastened into a chunk of cylindrical polystyrene. The center is firmly clamped to a five-foot angle-iron support attached at right angles to the mast. It is fed with RG-8/U coax. The pattern is quite circular. I regularly contact repeaters, full-quieting, fifty miles distant with 20 Watts. These repeaters are situated on the unfavorable side of the antenna, where the TV mast is between the antenna and the desired station.

For several years I had a traveling job and spent many nights in motels here and there in the midwest. My GTX-200, its power supply, and a portable dipole antenna all fit neatly into an attaché case. Thus, I spent many an evening in QSO with friends.

Due credit must be given the ground-plane antenna. It is every bit as good as a dipole. But I would not take a ground-plane-type along for portable work; in a motel room, those ground-plane rods can be dangerous. About the only place you can put a ground-plane antenna is on top of the TV set. Then two of the rods are pointing at the wall while the other one or two are pointing into the room to poke you in the nose, ribs, or whatever as you walk about the room.

My portable dipole might have been made from two pieces of rod stock fed at the center, but I had been experimenting at that time with inductive loaded elements. I decided to try an inductive-loaded dipole.

The two radiating elements of this dipole are formed from lengths of insulated #12 house-wiring wire, each approximately 23 inches long at the start. 3 inches from the center feedpoint, each wire is made into 5 turns of a coil wound on a 3/4" mandrel. Each coil is then stretched to approximately 4 inches long, evenly spaced, and epoxied to a cardboard tube or whatever light-

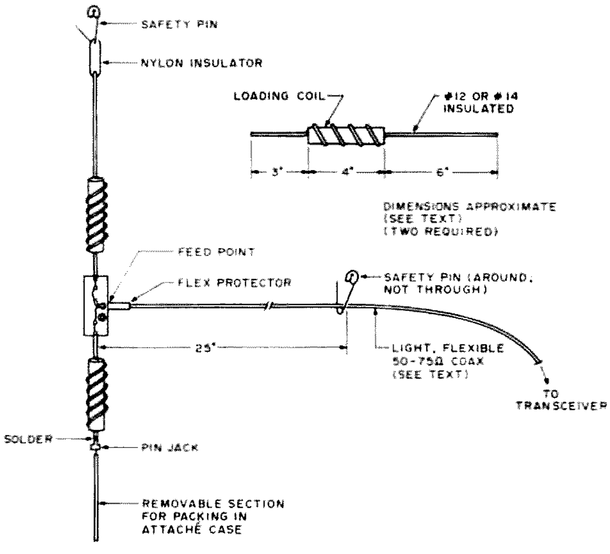

Fig. 1. The traveler's friend.

weight nonmetallic object can be found. See Fig. 1. Incidentally, modern house-wiring insulation exhibits good dielectric properties at 146 MHz, so leave the insulation on. Also, bear in mind that one must use a heavy 100-Watt, or better, soldering iron on wire this heavy.

A substantial insulating material block is used at the feedpoint to hold everything together. Each of the two radiating elements is securely bolted to the block. The coax center conductor is soldered to one of the elements, the shield to the other. Light, flexible 50- to 75-Ohm coax is recommended for feedline, unless you prefer to stuff 20 to 25 feet of RG-8/U into your attaché case day after day. Use a cable clamp to secure the coax to the block at the feedpoint. Maybe you can slide a few inches of protective tubing over the coax there under the cable clamp because frequent handling of your gear involves a lot of cable flexing. You don't want wear and tear to kill it before its time!

Find the dipole element connected to the center conductor of the coax. This is to be the top member of the dipole. Take about 1/2" of insulation off the very end. Form the bare end into a hook. Next, use scissors to make a strap 2" or 3" long by 1/2" wide cut from the top of a margarine container. Burn a small hole in each end of the strap using a pencil soldering iron (don't mind the smell). Then epoxy one end of the strap to the bare hook. Epoxy doesn't bond well to smooth nylon, so roughen up the surfaces a bit.

Remember, this dipole antenna is vertically polarized. This means that instead of hanging horizontally, it hangs vertically from one end.

Now put a diaper-type safety pin through the top hole of the insulator strap. This is to hold the antenna vertical while attached to the motel drapery. Some 25" away from the feedpoint, attach a safety pin to the coax, putting the pin around the coax, not through it. This is used to attach the coax to the drapery so that the antenna is fed 90° from its axis. Between this last pin and the transceiver, the routing of the coax is not critical.

As described so far, the antenna will not fit lengthwise into standard luggage. So, cut off the bottom element just below the loading coil and solder a pin jack at the recently cut coil end. Next, remove 1/2" of insulation from the piece cut off and insert it into the pin jack. Trim for symmetry.

Check the swr during construction, before the epoxy goes on. Hang the antenna from a rafter and, with tape, compress or expand the coils, searching for the lowest swr. If that doesn't work, house wire is plentiful; make another one. If you can improve this design, be my guest. Using it as described, I have had excellent results, so I did not try to improve it.

The best installation is where the drapes cover a picture window. You should try to place the antenna midway between the top and bottom, as well as midway between any vertical supports. Beware of windows with small panes. If metal-framed, these could upset your swr.

After your antenna is built and tested, don't be timid. On checking into motels, I would express my desire for an upper-floor room because I carried a two-way radio which reached out further from higher locations. No desk clerk ever gave me a hard time; their business is to fill the rooms with guests. ■

Two Meters for the Price of One

The oft-ignored shunt principle will turn an everyday junk-box meter into a surprising supermeter. The key is a piece of solder.

The philosopher William James was a champion of empiricism. Paraphrasing his definition of that awesome word: If I want to know if my pipe is lit, I will not perform endless rational operations examining cause and effect; instead, I will stick my finger in the bowl.

I became an empiricist recently (although not at such cost to my fingers) when confronted with the problem of using a 200-milliamp current meter to measure 2 Amperes of current. I knew there was a way, from years ago in tech school; it's called a shunt.

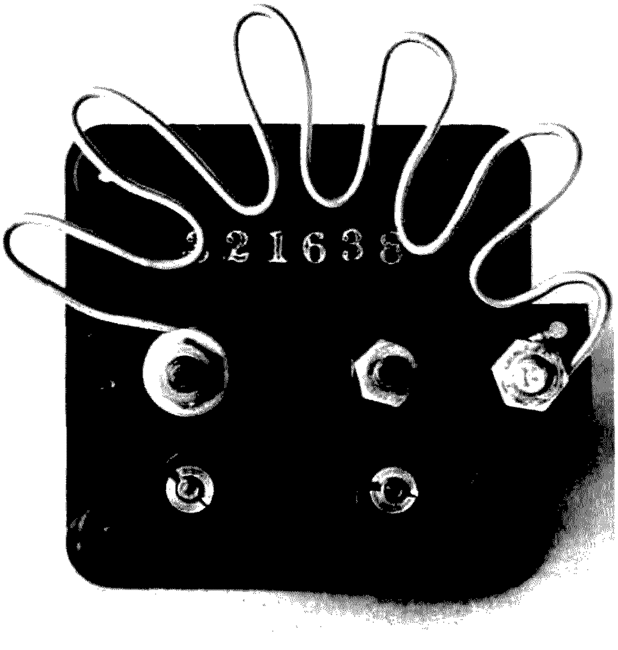
The shunt principle is nothing more than an expression of Ohm's Law. Current meters have a very low internal resistance, which we usually call negligible. It is some small fraction of an Ohm. Although current flowing through a resistance always generates heat, meter resistances are so small that the heat generated is carried away by the body of the meter.

If you place another resistance in parallel with the meter, current to the meter splits; part goes through the meter and part goes through the shunt. This split follows Ohm's Law faithfully. If the resistance of the shunt is precisely the same resistance as the meter, the current splits down the middle, and the meter indicates exactly one-half the true current flowing through it.

This sounds like a great way to make a meter tell lies. True, a 50-50 current shunt accomplishes little. The process gets interesting when the split becomes 90-10 with 90% of the current passing through the shunt and only 10% passing through the meter. In this arrangement, you multiply the apparent current reading on the meter by ten to get the true current. The numbers on the meter face still read true—all you have done is shifted the meter's decimal point! (I should point out that the various current ranges on VOMs force you to do exactly the same thing.)

Simple enough in concept—and very attractive since I had a good 200-mil meter in hand and a 2-Amp specimen would cost me six or eight bucks. Furthermore, by switching the shunt into and out of the circuit, I could have both current ranges with one meter. Since I was building a battery charger, I could indicate both fast charge current and the much smaller float charge current.

Fine—now, to build the shunt. My moth-eaten tech books had the theory, but the theory required that I know the resistance of the meter and be able to measure the resistance of the shunt. Since both values hovered down in the bottom quarter of an inch of the lowest resistance scale on my VOM, I realized that that method would not serve real-life needs. Rather than measuring or calculating at all, I decided to become an empiricist.



The empirical shunt, finished and in place.

The idea is disarmingly simple: Set up a shunt which is easily variable. Then pass the same current through the shunted meter and a VOM and vary the shunt until the reading is the same on both meters. At that point, the resistance of the shunt is correct because the results are correct, and calculation be damned! That's empiricism.

The setup I used is outlined in Fig. 1. An old-timer once told me of winding loops of solder around wooden spools for meter shunts. Solder is good shunt material because it has a relatively high resistance compared to copper. A copper shunt would be possible, but it would be much longer than a solder shunt.

I didn't even cut a length of solder off the roll. (You folks know what solder goes for! I wasn't going to waste a single inch.) I screwed the end of the solder roll under one meter terminal, pulled about a foot off the roll, and then pinched the solder under the other screw terminal leaving a loop of about ten inches in parallel with the meter movement.

Using clip-leads, I passed a current of two Amps through the two meters. The shunted meter went off the scale. This told me that not enough current was going through the solder. I reduced the resistance of the solder loop by shortening it by half. The next reading on the small meter was 110 mils. I had gone too far; now the solder loop was taking too much of the current. By pinching the solder loop off at different points under the terminal screw, I finally found a point at which the reading on both meters was exactly 2. The solder loop was about eight inches long. I cut the loop at that point and wasted no solder at all.

If you follow this process, the rules are simple. Shoot for full scale on the shunted meter. If your meter pins, shorten the shunt. If you fail to reach full scale, lengthen the shunt. This assumes, of course, that you have a current source adjustable to full scale on your meter. Full scale will give you the most accuracy, but if you can't rig just the right current, match readings and make the best of it.

Eight inches of solder seemed too little to wrap around a spool, so I compacted the loop by bending it back and forth into a number of smaller loops. I drilled two holes in a small piece of bakelite and clamped one end under the meter terminal. The other end of the loop I clamped through the other end of the bakelite with a small screw. I needn't mention the futility of trying to solder to a piece of solder. This arrangement allows me to switch the shunt out of the meter circuit to measure small currents.

The idea of having all those loops of bare conductor flapping around inside my charger bothered me, so I dipped the solder into the plastic insulation material normally used for dipping the handles of electrical pliers. You might also sandwich the solder loops between two pieces of thin plastic, which would also provide some mechanical support.

The solder I used was rosin core Kester 44, .062 inches in diameter. Smaller diameter solder could be used, but it is much flimsier and would have to be wound around something more substantial than thin air. Also, small solder melts more easily, so don't use it unless your total current through the shunt-meter combo is less than one Amp. Remember (and this is the only fly in the ointment) that if your shunt melts, full current will again flow through the meter, and unless you catch it quickly, you can kiss that meter good-bye.

Using this method, you can make a low-current meter read practically any larger current, within reason, all without calculation and the hair-tearing associated with all that sticky math stuff. You don't even have to stick your fingers in anything! ■

Strangle QRM with Your TS-830S

Simple filter modifications will help your Kenwood choke out interference. KA2R gives you the lowdown on how to do it.

The Kenwood TS-830S transceiver contains a fine receiver. It has numerous features and most of them work quite well. The two features that I find most useful in the TS-830S are the "VBT" and "IF Shift" controls. These two controls vary the i-f passband width and position respectively. When there is QRM on both sides of a desired signal, the VBT control can be used to move the skirts on both sides of the i-f passband inward, and when there is QRM on just one side of the desired signal, the IF Shift can be used to move the i-f passband away from the offending signal.

I found that these controls would perform their respective functions reasonably well but not as spectacularly as I had expected when I ordered the rig. I found that troublesome adjacent SSB signals could be moderately attenuated but not eliminated. I was especially disappointed to find that CW performance without optional CW filters installed was quite poor. The minimum practical passband setting was 500 Hz, and signals within 2 kHz of the desired signal were attenuated but not eliminated. This article describes a relatively straightforward modification to the TS-830S that significantly improves selectivity and increases the effectiveness of the VBT and IF Shift controls.

After owning the rig for several months, I went inside it to determine if I could improve the controls by optimizing the alignment. There was only one adjustment that would have any effect on VBT or IF Shift performance, and it wasn't far from its optimum setting (more on it later). I then studied the circuit diagram in detail to better understand the operation and the reason the controls were not performing as well as I had hoped they would.

VBT and IF Shift Circuit Details

The VBT operates by

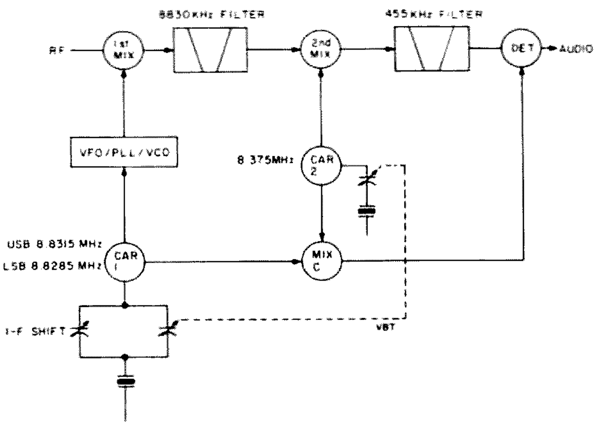

Fig. 1. IF Shift and VBT control details. Note that the IF Shift affects only the first mixer and the detector, thus shifting the i-f signal in both filters. The VBT increases the i-f signal frequency in one filter and reduces it in the other, effectively narrowing the i-f passband.

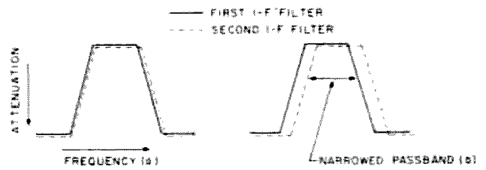

Fig. 2. The VBT control effect on overall i-f passband. The two filters are aligned as in (a) when the VBT is not in use. The VBT control effectively misaligns the two i-f filters, thus reducing the passband width as in (b).

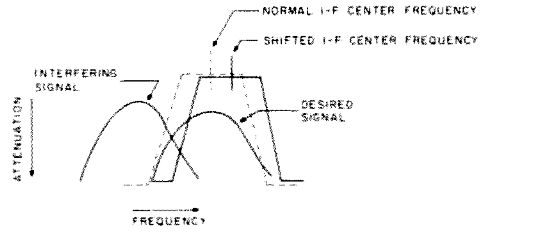

Fig. 3. Demonstration of IF Shift action in reducing QRM. Note that some of the desired signal is moved out of the passband along with the interfering signal.

shifting the frequency of the signal in the first i-f in one direction and the signal in the second i-f in the other direction. This is done by shifting the frequency of two of the oscillators that control the frequency of the signals in the i-f chain (see Fig. 1). The VBT control changes the frequency of an 8.83-MHz carrier oscillator and an 8.375-MHz i-f conversion oscillator (this oscillator converts an 8.83-MHz i-f signal to a 455-kHz i-f signal). Effectively, the two filters, normally in close alignment—Fig. 2(a)—are moved in opposite directions—Fig. 2(b). One filter provides the cutoff on one side of the passband while the other filter provides the cutoff on the other side. (For the purposes of Fig. 2, two identical, typical, filter characteristics are used. We will examine the actual filter characteristics provided in the TS-830S in a later figure.)

The IF Shift control changes only the carrier-oscillator frequency. This moves the signal the same direction in both i-f filters, cutting off the signal on one side or the other, as shown in Fig. 3. The VBT and IF Shift controls can be used simultaneously to select just one part of the incoming signal (the part that is not covered by QRM).

From the circuit details it would appear that, given ideal filters, the controls should work wonders at reducing QRM. Since their performance was less than spectacular, I examined the characteristics of the filters used in the TS-830S. I found the following:

- The 8.83-MHz i-f filter is a monolithic 8-pole crystal filter. Kenwood's specifications for it indicate a −6 dB passband width of greater than 2.7 kHz and a −60 dB passband width of less than 5.0 kHz. These specifications indicate a shape factor (−6 dB to −60 dB) of somewhat less than 1.85. The stopband attenuation of the filter is listed as 80 dB or more.

- The 455-kHz i-f filter is an 8-pole ceramic unit. It is specified to be 2.7 kHz or more at −6 dB and 4.5 kHz or less at −60 dB, for a shape factor somewhat less than 1.67. The "guaranteed" stopband attenuation is indicated to be 60 dB or more.

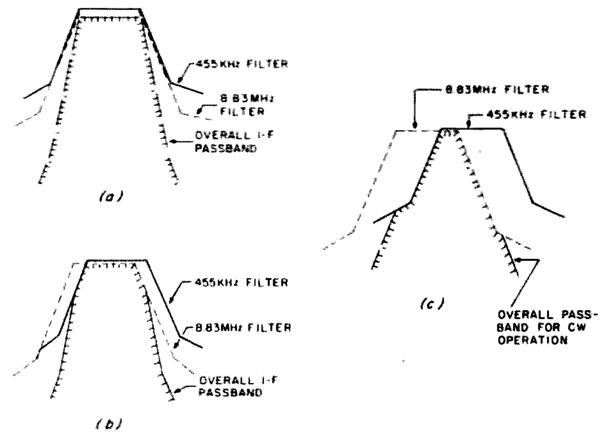

Fig. 4. At (a), the combination of the two filters provides a respectable overall i-f passband characteristic. At (b), the VBT is used to reduce −6-dB passband width; it only slightly reduces the −60-dB passband width. Use of the VBT and SSB filters for CW operation results in shoulders on the passband skirts as shown in (c).

Some tests on the TS-830S showed that the filters meet their specifications but that the 8.83-MHz i-f filter stopband attenuation is not achieved due to leakage past the filter on the i-f board. This, combined with the modest stopband attenuation of the 455-kHz ceramic filter, clearly explains why CW signals within 2 kHz of the desired signal are not fully attenuated when the VBT control is used to bring the passband width down to something suitable for CW operation.

The reason for the modest performance in both SSB and CW modes is demonstrated in Fig. 4. Fig. 4(a) shows the characteristics of the stock Kenwood filters in the TS-830S, along with the overall passband characteristic provided by the two filters when VBT is not in use. Fig. 4(b) shows how the passband skirt steepness is reduced when the VBT is used to bring the passband width down to about 2.0 kHz (my usual setting for operation on 20 meters). Note that the passband skirts are not nearly as steep as they are when the VBT is not in use. The shape of the passband in the region from −6 dB to −60 dB approaches that of a single filter as the VBT is cut in. Additionally, when the passband is narrowed by more than about 800 Hz, "shoulders" are formed on the passband skirts due to the limited stopband attenuation. This is shown in Fig. 4(c). The close-in stopband attenuation is limited to about 75 dB on one side (the 8.83-MHz filter side) and just over 60 dB on the other side (the 455-kHz filter side). Strong nearby CW signals are clearly audible if they fall within the region of limited stopband attenuation. And, of course, signals within the skirt area are going to be even louder than those in the shoulder area.

Improvement

From this analysis, it was clear that all I needed to make the TS-830S really perform well in the selectivity department were two ideal filters (i.e., filters with a 1.0 shape factor).

At this point, I recalled the successful "16-pole" modification I made to my TS-820S in 1979 (see the May, 1980, issue of the *Users International Radio Clubs Kenwood Newsletter*, published by N8RT). Even with VBT, the TS-830S was not providing the selectivity that my TS-820S provided after I added a second filter to it; since the TS-830S has two filters, it should be able to do at least as well as my old TS-820S. I decided that since the most significant difference between the modified TS-820S and the stock TS-830S was in the filters, upgrading of the TS-830S filters would surely be the key to improving its performance.

In previous similar projects, I have used filters purchased from the Fox Tango Corporation (Box 15944, W. Palm Beach FL 33406). This firm offers 8-pole, 2.1-kHz discrete-crystal filters in both 8.83-MHz and 455-kHz center frequencies. I have found their filters to have steeper passband skirts and higher stopband attenuation than the original equipment filters they are designed to replace. Since the TS-830S i-f skirt steepness and stopband attenuation are maximized when the two i-f filters are aligned (VBT not in use), I felt that the narrower passband width available in this line of filters would be particularly advantageous. Since I was operating the TS-830S with the VBT set for about 2.0 kHz most of the time anyway, I felt I might as well have filters that would provide that passband without the skirt steepness degradation that results from use of the VBT.

The original 2.7-kHz SSB filters in the TS-830S provide a −6-dB passband width of just over 2.4 kHz (VBT out) and are largely responsible for the reputation Kenwood has for excellent audio qual-

NEW TS830S for $150?

Yes indeed! Just add a Matched Pair of top-quality 2.1KHz BW (bandwidth) Fox Tango Filters. Here are a few quotes from users:

"... Makes a new rig out of my old TS830S! ..."
"...VBT now works the way I dreamed it should..."
"...Spectacular improvement in SSB selectivity..."
"...Completely eliminates my need for a CW filter..."
"...Simple installation - excellent instructions..."

The Fox Tango filters are notably superior to both original 2.7KHz BW units but especially the modest ceramic 2nd IF; our substitutes are 8-pole discrete-crystal construction. The comparative FT vs Kenwood results? VBT OFF — RX BW: 2.0 vs 2.4; Shape Factor: 1.19 vs 1.34; 80dB BW: 2.48 vs 3.41; Ultimate Rejection: 110dB vs 80. VBT SET FOR CW at 300Hz BW — SF 2.9 vs 3.33; Insertion Loss: 1dB vs 10dB.

AND NOW A NEW TS 930S!
Tests prove that the same filters improve the '930 even more than our '830. Don't buy CW filters—not even ours. You probably won't need them!

INTRODUCTORY PRICE: (Complete Kit)...$150

ity. I knew that two 2.1-kHz filters would reduce the −6-dB passband width to about 2 kHz and recognized that the audio quality would be affected. However, Heath, Collins, and others have long used 2.1-kHz SSB filters without owner complaint. Further, I applied cascaded 2.1-kHz filters in a Heath SB-102 transceiver some years ago and never regretted it for a minute.

Results

I installed the two Fox Tango filters in the TS-830S and found the results very gratifying. The following summary of my conclusions is taken from an earlier report published in the April, 1982, issue of the *UIRC Kenwood Newsletter*.

- The effect of the modification on audio quality is noticeable in a side-by-side comparison but is not bothersome in day-to-day use.
- The audio quality is far better than that provided by the optional 1.8-kHz filter offered by Kenwood and several other transceiver manufacturers.
- The VBT is now used less often and to a lesser degree when it is needed because the basic passband is closer to the ideal for today's crowded bands. The shape factor (−6/−60 dB) of the modified rig is 1.19 compared with 1.45 for the stock rig set for a comparable passband width.
- The VBT control, when used to combat QRM during SSB operation, is now generally used to bring the passband down only 200 or 300 Hz, leaving the shape factor quite high (i.e., the skirts remain relatively steep and shoulders are not formed on the skirts).
- The IF Shift is significantly more effective because of the steep, deep skirts provided by the two 2.1-kHz filters.
- The VBT can be used to bring the passband down to about 300 Hz, making CW operation with only SSB filters installed quite practical. With the VBT set at 300 Hz, the CW passband shape approaches that of the optional Kenwood 8.83-MHz, 250-Hz CW filter.
- With the VBT set at 500 Hz, the passband shape factor is considerably better than that of the optional Kenwood 500-Hz, 8.83-MHz CW filter.
- With the two 2.1-kHz filters installed, I found I could run the rf clipping higher without complaints of audio quality degradation.
- In most on-the-air tests I have been told that the combination of the new filters and a Shure 444 mike provides impressive punch. No one has yet observed any unusual quality in my transmit audio when I am using a Kenwood MC-50 mike.

Replacing the 8.83-MHz i-f filter with an improved unit does not eliminate the 8.83-MHz i-f board leakage but significantly reduces its effect on SSB operation since less VBT must be used to fight QRM. In CW operation, the limited stopband attenuation in the 8.83 i-f is still sometimes noticeable. However, the stopband attenuation of the new 455-kHz filter appears to be greater than −100 dB and provides nearly this level of attenuation when installed in the Kenwood 455-kHz i-f circuit, reducing the effect of the more troublesome of the two shoulders.

Installation

Both replacement filters are larger than the original filters (the 455-kHz filter is about 10 times larger than the small ceramic filter it replaces), but there is plenty of room for mounting them above the i-f board in the TS-830S. The discrete-crystal filters have built-in isolating transformers and thus, unlike the monolithic crystal and ceramic filters used by Kenwood, require isolating capacitors. These can be mounted right on the new filters. Short pieces of RG-174 coax can be used to bridge between the i-f board and the new filters.

I will not go into detail on the physical installation of these filters here; the manufacturer now offers the two required filters in a kit complete with coax, capacitors, and instructions. The kit instructions detail several installation options. Those who have no CW filters installed can have automatic or manual switch selection between the original filters and the new 2.1-kHz filters and can select the desired filters independently for receive and transmit operating modes. Incidentally, the 455-kHz crystal filter is a rather expensive item at $125. However, I understand that the kit will continue to be offered for some time at its current introductory price of $150.00 plus $3.00 shipping.

The minimal alignment required during the modification is readily facilitated by the built-in calibrator oscillator and the S-meter. For those who have a frequency counter handy or can borrow one, the 8.375-MHz oscillator can be trimmed to put the two 2.1-kHz-filter center frequencies in perfect alignment. This step maximizes the −6-dB passband, bringing it up to about 2050 kHz. It also maximizes the steepness of the passband skirts.

Conclusions

I have been living with the modified TS-830S for over 6 months now and still get a kick out of foiling the QRM in a way I couldn't before making the modification. I've talked with several others who have made the modification, and all have been very pleased with the results. I will be happy to respond to anyone with questions on this modification. Please ensure my reply by sending me an SASE! ■

Smart Meters: The New Movement

Turn your passive meters into active error-correction systems. W4RNL's innovative circuits make it a snap.

The housewife doing laundry and the ham have much in common. Both depend upon indicators to tell them when their equipment is doing a good job, and their indicators often fail them. The housewife does not see the light on the clothes dryer go out, and the wash-and-wear sits in a wrinkled pile for an hour. The ham does not notice the current climb on his plate meter, and finally a fuse blows—or the final does.

Both cases illustrate a limitation in our thinking about monitoring the operation of our equipment. For the most part when we think about monitoring our gear, we picture meters or other indicators that tell us the current status of things. Then it is up to us to make the proper moves to resolve any problems. Too often, however, we fail to keep an eye on the indicator and the problem gets out of hand before we can step in with corrective action.

There is a solution to this difficulty. The first step is to change our thinking about monitoring. The second step is to put together a few handy circuits which will both reflect our new way of thinking and take some corrective action for us. Although there are many ways to control conditions that are straying, we will limit ourselves to some variations on circuits using just a few components. The heart of the circuits will be two common ICs: the 555 timer and the 339 voltage comparator. Both are very simple to use and subject to nearly limitless variations in the functions we can get them to perform. But first, a few words about thinking.

Monitoring—Detect and Control

The solution to the housewife's problem is simple: To the clothes dryer we add a buzzer which sounds off at the end of the drying cycle. Then she can come promptly to remove the clothes before they wrinkle. What has been added to the situation is a method to ensure that the harmful condition—namely, the clothes sitting and wrinkling—will not proceed unchecked for very long. The control system is not perfect, of course, but few things are. The lady may leave the house or be out of earshot of the buzzer. But to a large measure, we have brought the undesirable situation under control.

Household appliance manufacturers have long recognized the problem and built buzzers into appliances (and added bells, whistles, lights, and other control signals). Hams have not been nearly so up to date in their methods. We continue to think of monitoring our equipment almost solely in terms of a few meters to provide us with status reports—if we are in a position to see them or take the trouble to look. But meters and other indicators are only one half of the job of monitoring. Monitoring consists of two parts: detection and control.

Once we understand this fact, it is easy to see why meters can do only half the work. They provide an indication of both normal and abnormal operation, but they do nothing to control the abnormal condition. They sit there happily indicating that our equipment is going to pot without lifting a finger to help.

Unless we have unlimited time and money, developing a perfect control system to correct any and all undesirable conditions is not a practical solution to the second part of the monitoring problem. Neither does the housewife have a dryer that will remove and hang the wash-and-wear clothing when the cycle is complete. She depends on the monitoring device—the buzzer—to ensure that something appropriate gets done. And that is the task we should have in mind when we try to design effective monitors for our ham equipment. We may not be able to have every circuit self-adjust, but we can take steps to make sure that when the gear acts up the monitoring system will

take an action that will protect the equipment.

There are several types of control actions at our disposal. Let's list them by categories as a convenient way to decide for each case we run into what the best system may be.

1. *Self-adjustment.* Although this step is not practical for every monitor, it is relevant to many and much more common than we might believe. Automatic gain control and automatic frequency control are just two of the many self-correcting control actions that occur in ham gear. But in most of the places around the shack that call for detection and control, automatic adjustment would be too complex and costly, and often simply unnecessary.

2. *Automatic Switching.* In some cases, an out-of-spec condition can be controlled by switching to a safe mode of operation—perhaps a lower power setting. We can go so far as to switch the equipment off, but let's save this possibility for a special category.

3. *Warning.* If we can detect a harmful condition while it is on the borderline of trouble, we can take preventive action manually. However, we need to catch the problem promptly, which requires a warning method that we cannot ignore. Bells, buzzers, lights, and sirens are all quite effective in waking most of us. These are some of the easiest and most important systems to design.

4. *Shutdown.* Ultimately, the final safety measure is to have *our monitor* shut down the equipment before a problem has the time to cause a catastrophe. In most instances we would prefer to keep the equipment going if we can, but some conditions call for total removal of power. Thus we have a new way to look at the common fuse: It monitors current and, in the event of serious overload, it protects the equipment by sacrificing itself—poor fellow. Nonetheless, the fuse is a clue to when we should think about shutdown as *our* control step. We pull the plug when the condition is dangerous or destructive.

These four categories cover almost all the types of detection and control systems you will encounter or develop. Translating these general ideas into practical ham designs may seem to be a complex task. However, with just two or three ICs, we can make a good start toward effective monitoring.

Some Basic Methods for Monitoring

Since we need both a method of detection and a method of control, let's start with separate devices for each job. For our detector, we can use the LM339 voltage comparator. Our basic controller will be the ubiquitous NE555 timer. We may add a few chips along the way, but together these two inexpensive ICs will allow us to design a large number of useful monitoring systems for both the ham shack and the home.

The LM339 voltage comparator is but one of a vast array of op amps that could perform the detection role well. I chose the 339 for several reasons. First, unlike some op amps, it requires only a single power supply and it operates in the 5-to-15-volt range of the 555 timer. This is also the range of voltages we may need for other devices we add to the system, and it is also the range we are likely to find or can derive from existing power sources in the equipment to which we add the monitor. Second, the 339 comes four comparators to a DIP for a low cost per section. Fig. 1 shows the pinout. Finally, for basic comparator work, the chip is easy to use.

Fig. 1 also shows the basic circuit for voltage comparison work. The 339 will drive

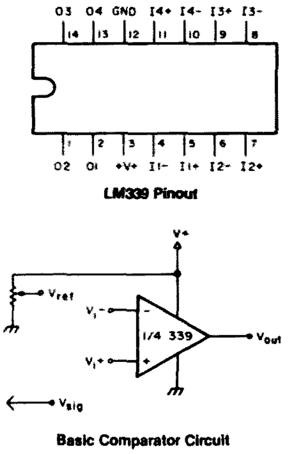

Fig. 1. Pinout and basic comparator circuit of the LM339.

either CMOS or TTL chips. For a non-inverting comparator, that is, one that changes its output from low to high as the input voltage rises, connect the reference voltage to the inverting input (Vi−) and the signal voltage to the non-inverting input (Vi+). To make an inverting comparator, reverse the input connections and the output will drop from a high to a low as the signal voltage rises above the reference level.

Fig. 2 shows more practical circuits recommended by National Semiconductor. Each adds feedback for hysteresis in order to prevent oscillation and chatter. Since many of the applications of the comparator as a detector for monitoring will be faced with noisy or slowly-changing voltages, the

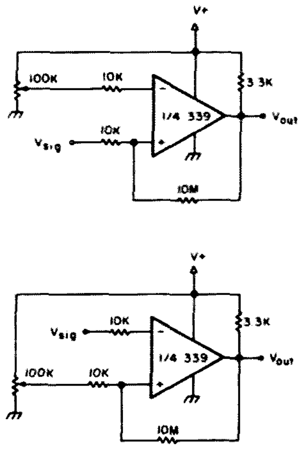

Fig 2. Two practical comparator circuits for the 339. Inverting and non-inverting (bottom) comparators.

feedback is wise and inexpensive. Too, the exact values are not critical.

Although the input voltage should not exceed the supply voltage by much (as a general rule of thumb, not at all), we are not limited only to monitoring voltages from 0 to the chip's supply voltage. We can drop high dc voltages through a series-resistance voltage divider, using high-value resistors to minimize the current load on the monitored circuit. Fig. 3 shows a sample case (a) lowering the nominal 1000-volt supply to 10 volts. The voltage at the op amp input will proportionally track the changes in the 1000-volt line.

As long as the input voltage to the comparator is

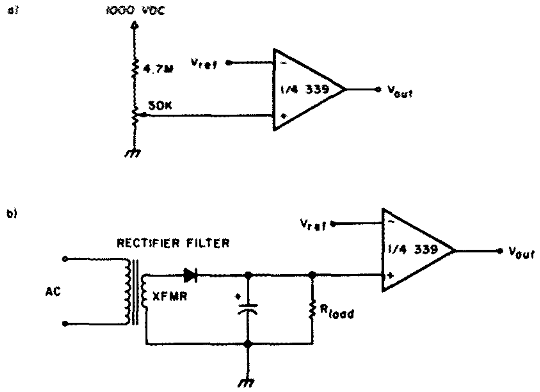

Fig. 3. Deriving input voltages from high ac and dc sources. (a) Using high dc sources. (b) Using high ac sources.

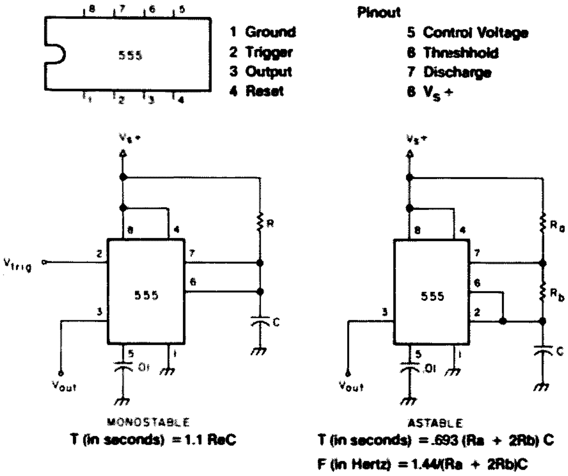

Fig. 4. The basic 555 configurations.

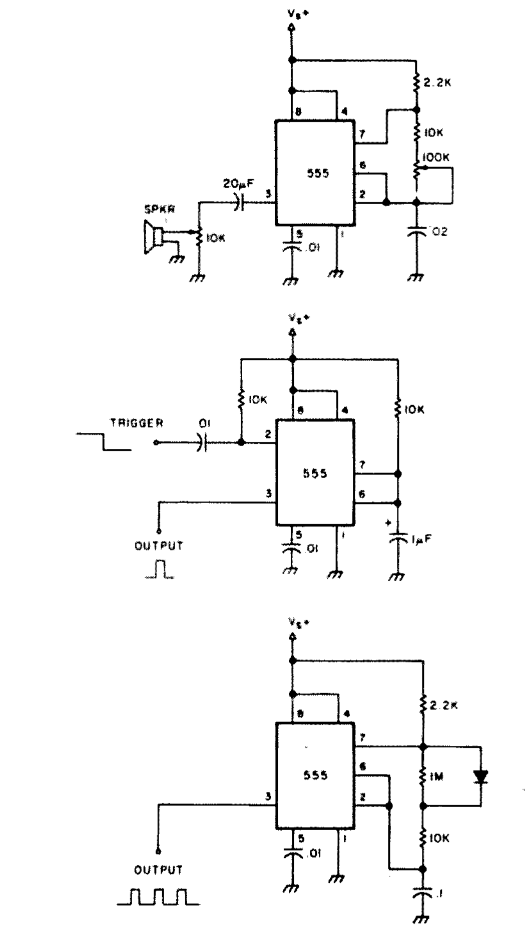

Fig. 5. Three typical 555 circuits. Top to bottom: audio oscillator, one-shot pulser, pulse generator.

within safe limits and tracks the line it samples, we need not be too concerned in these applications with the exact voltage. In each case we will set the reference voltage for the other input to cause the comparator to change its output state at the proper level of the line we are monitoring.

Similarly, by converting ac voltages to a safe level of dc, as shown in (b), we can use the comparator to monitor ac levels. The only precautions in this case are these: First, have a steady minimum load on the transformer so that it will track correctly, and second, the more sensitively you want to track, the more filtering you will need in the ac-to-dc conversion.

The 339 detector portion of our system is most applicable to the last three categories of monitoring. For cases in which we need automatic adjustment, the comparator is not often the best way to achieve our goal. However, for automatic switching, warning, and shutdown, the definite change of state of the comparator is ideal to trigger control devices such as the 555 timer. Moreover, since changes in voltage, current, resistance, and power can all usually be converted into changes of voltage, we can effectively monitor most of the important functions within our equipment.

The 555 timer has become an instant legend as a versatile timing and control device. Fig. 4 shows the pinout, the basic monostable and astable circuits, and the timing formulas for the IC. Since the output stage will supply up to 100 mA of current, it is ideal for driving lamps, relays, small buzzers, sirens, and a host of other units. By chaining 555 stages, we can build delays into the control system to allow for self-correction or other factors. Too, the 555 makes a excellent square-wave oscillator for audible warnings, and it can be used to generate pulses for various applications. Fig. 5 shows an audio oscillator, a one-shot pulser, and a continuous-pulse generator as samples of what the 555 can do.

With all these tools at hand, we are now ready to look at some practical circuits. In one form or another, all of them are at work in pieces of equipment around the shack and house here. A few have actually prevented some expensive disasters, and one is at work keeping my wash-and-wear shirts from being wrinkled in the dryer.

Some Practical Circuits

Let's begin with a pure ham application. On occasion, the plate current to my final amplifier has risen to dangerous levels—at least to levels which threaten to shorten the lifetime of the tubes. This has occurred as the tubes aged and lost their perfect balance, as well as in the case of a number of careless retunings. Noting that the high voltage dropped with the rise in current, I added the circuit in Fig. 6 to warn me of excessive current. The resistor divider samples less than 4/10 of a percent of the high voltage. When the voltage drops due to excessive current, the 339 triggers the oscillator and a transistor switch for the warning lamp. The 100-μF capacitor in the signal-voltage line counteracts brief voltage drops caused by normal peak demands of speech or CW keying. You may have to experiment with this value for your system. The object is to have the monitor respond only to the relatively slower changes of current. I set the reference threshhold of the comparator by monitoring the current levels at which the comparator triggered the system.

The circuit is placed well away from heavy rf fields, with only the low-voltage signal line emerging from the amplifier. The line is shielded and well filtered to keep rf out of the monitor itself. The unit is in a small box of its own behind a panel directly in front of me, so that I cannot miss the warning light—or sound. Perhaps the most significant event in the life of this little monitor was when it sounded off to

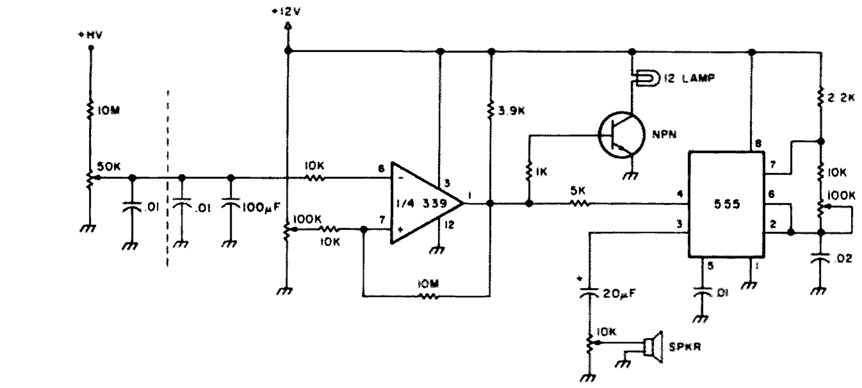

Fig. 6. An excess-current-warning monitor.

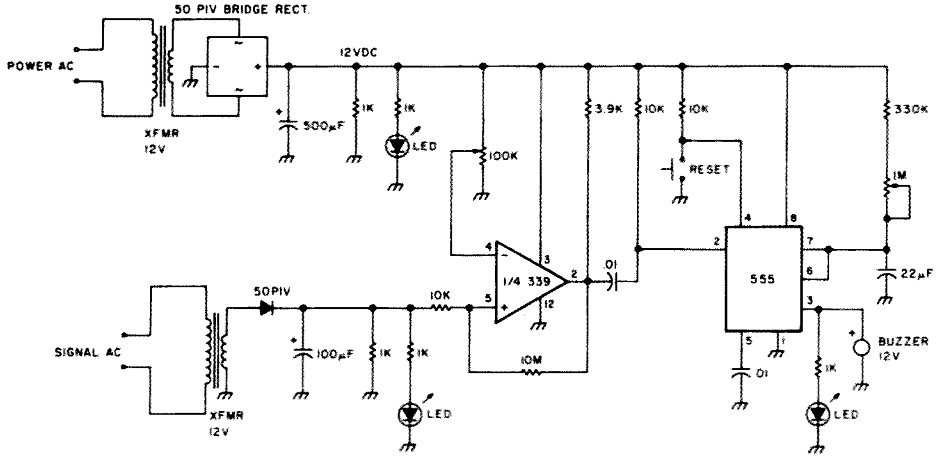

Fig. 7. An end-of-cycle monitor for ac equipment.

warn me of an over-current condition, and the fuse in the high-voltage line refused to blow. What that might have cost me had the monitor not been in place, I shudder to think about.

In case you may be wondering about my shirts, an old but perfect clothes dryer lacked a warning buzzer to signal the end of its cycle, although a light in the timing wheel did go off. Fig. 7 shows the answer to the problems created when someone did not see the light go dark: Another 339 responding to the shutdown triggers a 555 monostable, which in turn lights a light and sounds a buzzer that can be heard throughout the house. The monostable has a variable duration of 10 to 40 seconds (it calculates at 8 to 32 seconds, but most electrolytics are a bit leaky and extend the time period). A reset button allows one to cut the sound if nearby. The input circuit uses the smallest 12-volt transformer I could find, since the current requirements are minimal, most going to the 1k bleeder resistor and to the LED. The reference potentiometer setting is non-critical: about midrange does well. The goal is to convert the slowly decaying voltage from the ac-to-dc converter to something sharp enough to trigger the 555 reliably. By setting the reference low enough, the circuit will not falsely respond to line-voltage drops occasioned by the central air conditioner compressor when it starts to compress.

Fig. 8 shows a variation in the dryer theme. Comparator #1 senses a drop in voltage and triggers the first 555. This timer acts as a delay so that the condition has time to correct itself before the second 555 begins a control cycle. If the condition does correct itself, comparator #2 cancels the control action by bringing the reset line of the second 555 to ground. For ac applications, the second comparator might be set at about 50 volts so that a generator will not start with even some of the power company's voltage on the line. The second 555 output can be tied to the starting circuitry of the generator through a relay. Other applications of this circuit for both ac and dc conditions can readily be imagined.

As a variation on this two-level circuit, Fig. 9 shows a 339 coupled to a 7400 NAND latch. Section #1 of the 339 pulls the latch output high as its input voltage drops below the threshhold, while section #2 pulls the output low as the voltage climbs again. For reverse action, take the output from the other NAND gate. The input to the two comparators can be ac- or dc-derived, with the two sections having any desired differential. The NAND gates are separated from the comparator so that they respond to pulses created by the capacitor discharges; hence, the latch never faces dual low inputs. The output of the latch, unlike the 555 timers,

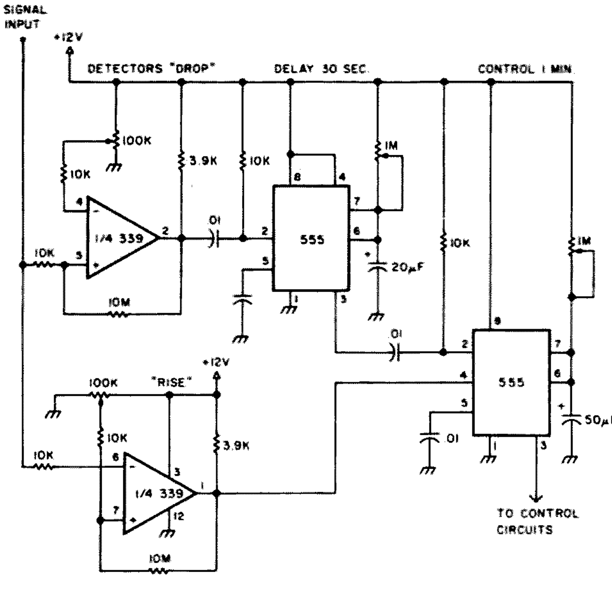

Fig. 8. A monitor with delay and cancel features.

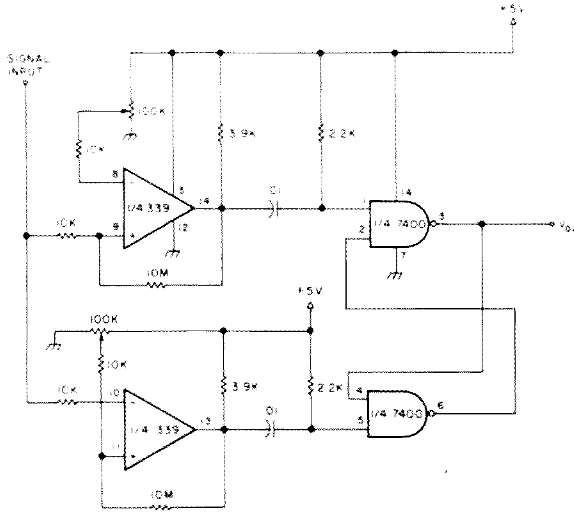

Fig. 9. A monitor with a latched output.

remains high as long as the low- or 0-voltage condition persists.

By reversing the positions of the inverting and non-inverting comparators, we can use essentially the same circuit to detect and control voltages which exceed safe levels. As an alternative, we can keep the comparators in the same order but use NOR gates for the latch. Any IC handbook will provide a number of circuits that the voltage comparators can trigger for various types of control or warning purposes.

For instance, adding a simple counter to the latch shown in Fig. 9 will reveal the number of times each day that the power company drops its ac part or all the way out.

These few samples should provide you with ideas of your own for monitoring circuits to use around the shack and house. (I add "the house" because putting my ham experience to work in the laundry room earned me several points toward the new rig I wanted.) There is little magic in the 339 that some other comparator (or a more general op amp pressed into comparator service) could not provide. However, to the extent possible in today's morass of proliferating ICs, I try to master a few chips well and use them extensively. Hence, the faithful 555 serves many purposes in my shack.

More important than the particular circuits and components we use for our systems is the general conception of monitoring. The presence of meters and even of lights may not suffice to protect our equipment from dangerous or harmful conditions. Monitoring must have a control function as well as a detection function. It is not always necessary for our control systems to correct the situation as long as they at least protect the equipment from its effects. And if the system requires action on our parts, the warning must be undeniable in its effort to capture and direct our attention to exactly the right place to make adjustments.

Hopefully, these circuits and ideas will bring us a few steps beyond mere metering (as important as that may be) toward more effective monitoring. What we save in the long run just might be more than money. ■

80M IN 24 FT!

Put a broad bandwidth 80M dipole in 24 ft with the SLINKY DIPOLE® antenna. Comparable low SWR, space savings and performance on ALL HF bands, including SWL and WARC. Complete kit: 2 special 4" coils, 50' RG-58/U coax, balun kit, mounting hardware and instructions. Great for apartments, condominiums, motels and vacation use. Easy set up and adjustment.

A QSL Assembly Line of Your Very Own

The problem: a stack of QSL cards as high as Mt. Everest. The solution: a program that will make your TRS-80 climb the mountain.

After a recent contest, I got started on the job of filling in the QSL cards for all the contacts with foreign stations that I had worked, as is my policy. As soon as I started, I knew that there was something wrong—I was slaving away filling in the QSL cards and the TRS-80 was only watching.

Instead of giving Wayne all my money for QSL cards, why don't I use the TRS-80 and the line printer to print my own QSL cards and have the computer fill them in while it is printing them?

It seemed like a good idea to me, so I set out to write a program to do it. Sometime later, the program was finished in Level II BASIC and I happily began printing QSL cards.

After I had finished the

contest logs, there seemed to be two improvements needed. One was that it took 45 seconds to print each card, which meant that I had to wait for the printer to finish so that I could enter the data for another QSO. The second was that the date, band, mode, and report were quite often the same for each QSO, in which case I wanted to hit only the Enter key instead of having to type in all of that info for each QSO when it was the same as for the previous one. The first problem was solved by using arrays in the input statements, and the second was done with line 143 in the program listing.

Let's go through the program so that you can modify it according to the amount of RAM and graphics ability of your printer. On power-up of your TRS-80 you are allowed 50 spaces for strings. This will not be enough for this program. In line 40 I have increased to 30000. This line will have to be adjusted according to the amount of RAM that you have available. It will be very easy to see when you have made the number too high—you will see "overflow in line 40" when you try to run the program. If this happens, just reenter line 40 using a lower number. In line 45 I have set the dimensions of the array to enter 100 QSL cards to be printed at one time. However, I would not suggest printing that many at one time, as the more you enter into memory, the longer it takes for the callsign prompt to return. What I do is enter one page from the log book at a time, then print the QSL cards before going on to the next page.

Lines 50 through 140 input the log data for each QSO. After the info for the first QSO is entered, you will see a number in the top right-hand corner of the screen. This is the amount of string space left. Do not take this number down to zero unless you want to crash the program. Under the amount of string space available is the number of QSOs that you have entered into memory. This number will be needed later.

After you have the string memory available and the number of QSOs entered, you are prompted for the next QSO's callsign, then GMT. On the next line you will see a number which represents the date on the previous QSO logged and the date prompt. If the date is the same for this QSO as for the previous one, then all that is necessary to do is to hit the Enter bar. If the date is different, type in the new date before hitting the Enter bar. Use the same procedure for band, RST, and mode.

After you have entered the log data for all the QSLs you want to be printed or the number in the top left-hand corner approaches zero, it is time to print the QSL cards for the QSOs in memory. This is done when you have the callsign prompt by entering "End." You will then get a prompt asking for the number of QSLs to be printed. This number is available from the top right-hand corner of the screen. Just enter that number and the printer takes over, and you can go back to the receiver while the printer is busy printing.

If your printer does not have graphics or elongated or condensed print, you will want to make the following changes in the printing routine. Omit lines 260 and 331. Delete the CHR$(31) in line 190. Next take out all of the CHR$(255) in lines 270, 290, and 310 and delete the CHR$(29) in line 350. If your printer does have graphics and elongated and condensed print, it is possible that the software command, CHR$(N), is different

than mine. I suggest you check your printer manual to be sure.

At first I bought 3" × 5" tractor-feed forms to print my cards on, but I soon learned that they were too large and bulky. Most of my cards go via the ARRL Outgoing Bureau, and they now charge by the pound, so I am using the lightest weight paper that I have and using the scissors to trim after the printing is done.

This program was written by a novice programmer. I am sure that many of you more experienced programmers can make vast improvements on it. The purpose was to get the seed planted, in hopes that you experienced programmers might come up with some real exotic cards (how about a computer-generated QSL contest, Wayne?), and also to show other novice programmers that perhaps they might be able to come up with a useful program.

This program should be convertible to the BASIC used in other computers. ■

Get Accurate with the Digital-Grid Power Meter

Your final input power is instantly accessible with this easy add-on.

FCC regulations still require measurement of the input power to a rig. This is normally accomplished by multiplying the plate voltage times the plate current and adding to it a few Watts for screen power and drive power if these are applicable.

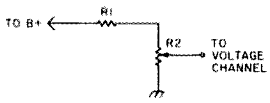
The LED power meter, whose faceplate is shown in Fig. 1, provides a direct readout of the plate or collector input power not only in the tune or key-down position, but also as you either talk on SSB or key the rig in CW. I would not go so far as to claim that it shows peak envelope power—PEP—on SSB, but it comes very close!

The meter operates in a single simple mode. After connection and calibration, simply find the highest LED energized in both columns, trace to the intersection, and read the input power directly. For example, if LED 8A (on the voltage scale) and LED 5B (on the current scale) are the two highest LEDs energized, their intersection tells you that the input power is 400 Watts.

A block diagram of the meter is shown in Fig. 2. Two similar LED voltmeter channels are used, one to measure plate current (or collector current) and the other to measure plate or supply voltage. Each channel is independently calibrated so that the maximum voltage or current it will see corresponds to the highest LED shown. The unit pictured here had the highest LEDs corresponding to 1000 volts and 1000 mA.

The LED voltmeter connected to the voltage-monitoring channel consists of a simple zero-to-1.2-volt sensor. An adjustable voltage divider is used to scale the plate or collector supply voltage to the 1.2-volt range. A similar circuit is used for the current channel, but the LED voltmeter sensitivity is increased so that the approximately ¼ volt (250 millivolts) is the full-scale sensitivity.

A schematic of the meter is shown in Fig. 3. Resistors R1 and R2 are selected according to Table 1 for various supply voltages. Note that R1 is shown mounted in the rig. In this way if the lead from the rig connecting R1 with R2 accidentally shorts



R \ B+	1000V	50V	20V
R1	1 MEG 2W	5K 1/2W	300Ω 1/2W
R2	10K 1/2W	500Ω 1/2W	100Ω 1/2W

Table 1. Voltage channel divider and calibration resistors.

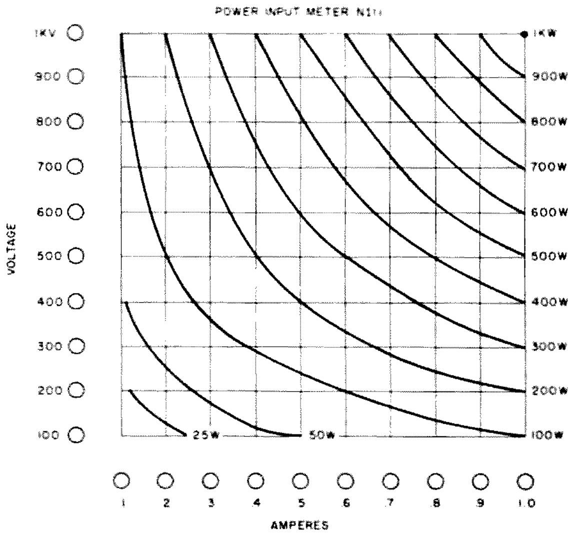


Fig. 1. Faceplate of power input meter.

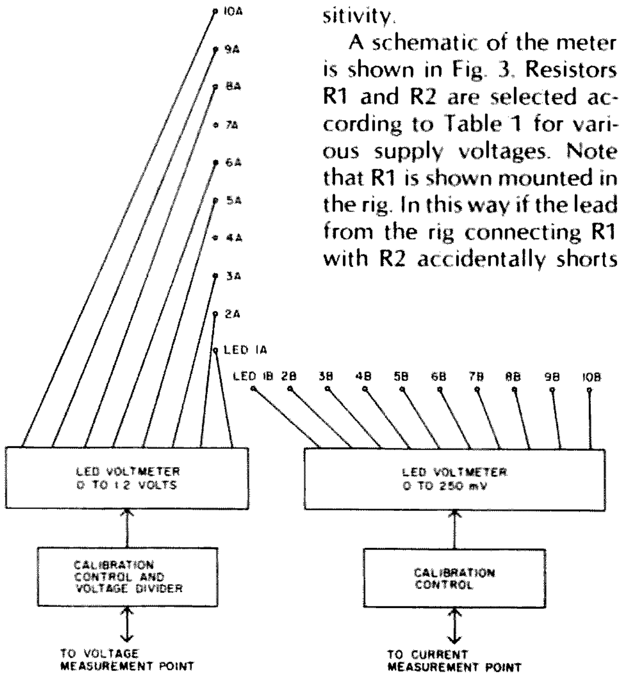

Fig. 2. Block diagram.

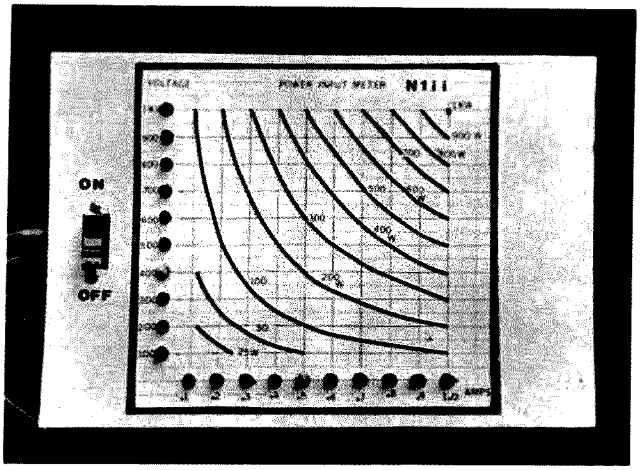

Front panel of the LED power input meter. (Photo by Jerry Goldman K1NPE)

to ground, the current drawn will be limited by the value of R1. If you are using a tube transmitter: *CAUTION—HIGH VOLTAGE!*

You will have to look at the schematic of your rig to figure out where to connect the current channel. Most rigs, tube or transmitter, use a meter with one side connected to ground, in which case the current connection lead probably goes to the top (non-grounded) side of the meter. A typical connection is shown in Fig. 4. To check that the connection point you have selected will work, connect a voltmeter between the point and ground. No current should correspond to zero volts and maximum current to at least ¼ volt (250 millivolts).

Construction of the meter is not critical. A 6½" × 6½" plastic panel was used as the faceplate with the two sets of LEDs mounted on ½-inch centers (Fig. 5). To avoid the use of a custom PC board, a general-purpose board such as Radio Shack 276-170 provides a good chassis for construction. As usual, sockets for the two ICs are recommended to aid in troubleshooting, if necessary. The layout used for the breadboard of this meter is shown in Fig 6.

After drilling the holes for the LEDs on the front panel, a piece of graph paper marked with half-inch intervals (such as K & E 10 × 10 to the half inch) is glued onto the plastic for the scales. A clear plastic spray or drawing fixative can be applied to protect the writing.

You can scale the meter to match your rig. As an example, for a typical vacuum-tube rig using 800 volts and around 250 mA, the voltage scale should be left at 1000 volts maximum but the current scale changed to 500 mA maximum. To do this, simply relabel the current scale so that LED 1B corresponds to 50 mA, 2B to 100 mA, 3B to 150 mA, and so on until 100 corresponds to 500 mA.

When you divide the current scale by 2, you must divide the power curve labels by 2. Therefore, the 100-Watt curve is now labeled 50 Watts, the 200-Watt curve relabeled 100 Watts, and so on. If you reduce both current and voltage scales by 2, the power curves go down by 4 (i.e., 400 Watts is relabeled 100 Watts).

After construction, the checkout and calibration should take only a few minutes. Double-check your wiring and look for extra solder splashes, especially around the IC sockets. Disconnect (unsolder) the wires at points X and Y (Fig. 3) and connect both TP1 and TP2

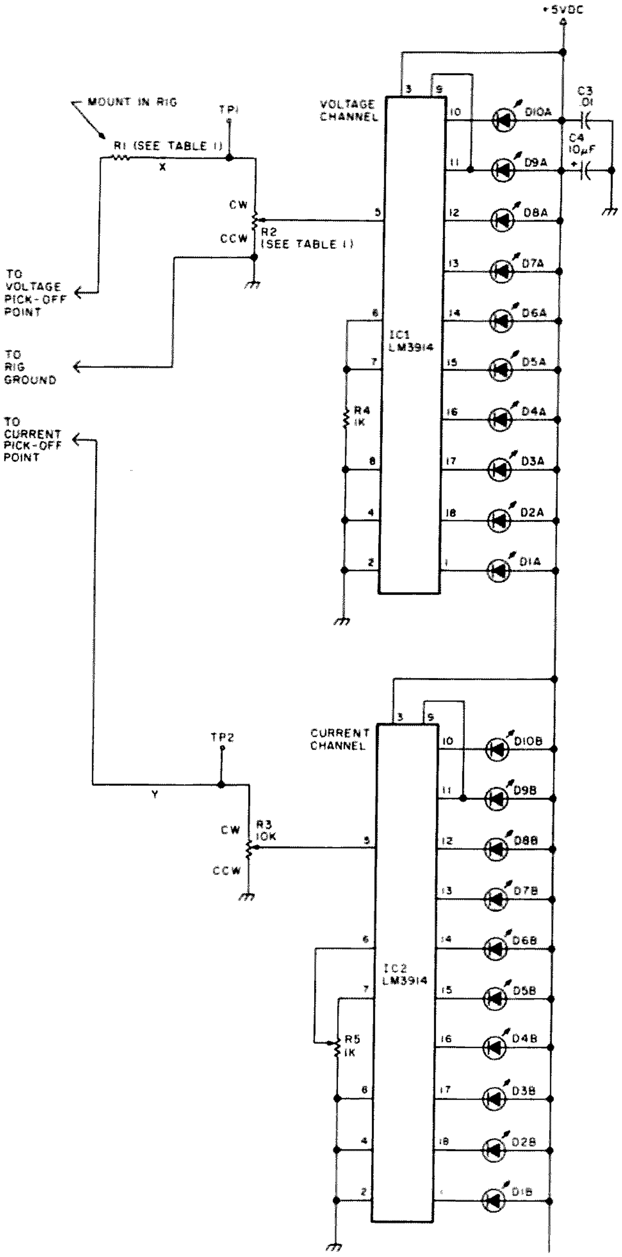

Fig. 3. Schematic. IC1, IC2—LM 3914 (Radio Shack 276-1707). All other resistors ½ Watt. All capacitors 50 V dc.

to the 5-volt supply. Set R5 to its midpoint.

Now apply the 5-volt supply and check that you can sequentially light each of the LEDs in each of the channels by turning R2 and R3. Assuming that you can, it means that each channel works and you are ready to calibrate the system.

To calibrate the voltage channel, turn off the 5-volt supply, disconnect the jumper from TP1 to the 5 volts, and reconnect the lead at point X which you previously disconnected.

With the rig off, attach both the ground lead and the B+ end of R1 to either the high voltage of your rig or any other similar high-voltage supply. Take a standard voltmeter and also connect to the same high-voltage supply. Next, turn on the high-voltage and +5 supplies and adjust R2 so that the proper LED is ener-

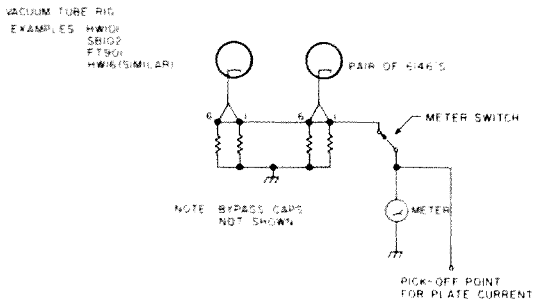

Fig. 4. Typical connections for current pick-off.

gized. As an example, if you use an 800-volt supply, LED 8A (for the scale shown in

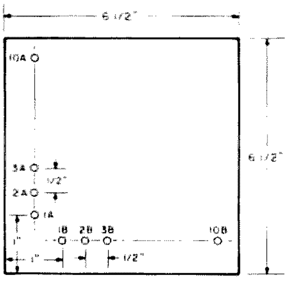

Fig. 5. Front panel layout.

Fig. 1) should be on. Finally, turn off the rig and the 5-volt supply. The voltage channel is now calibrated.

Calibration of the current channel is very similar, but first the sensitivity must be set since the current channel is a 250-millivolt unit rather than the basic 1.2-volt sensitivity of the voltage channel.

Remove the jumper you previously connected from TP2 to the 5-volt supply and jumper TP2 to ¼ volt by building the circuit in Fig. 7 and adjusting the 1k pot so that the voltmeter reads the needed ¼ volt. Turn R3 full clockwise and adjust R5 so that the last LED (10B) is energized.

Finally, turn off the 5 volts from TP2, reconnect the lead at point Y, and connect the current input to the meter on the rig or wherever you are going to measure current.

The final step is identical to the one you already did for the voltage channel. Turn on both the rig and the 5 volts. Key the rig and measure the plate current using the existing plate-current meter. Set R3 so that the LED corresponding to the current is energized. As an example, if the meter reads around 300 mA, then LED 3B (for the scale shown in Fig. 1) should be on.

Checkout, installation, and calibration are now complete. Simply talk or key the rig, look for the highest LEDs lit, and read input power directly.

If you insist on being very precise, this meter does not account for drive power and uses the plate voltage instead of the screen voltage in measuring the tiny contribution of the screen-input power. However, in most cases you will be within a few percent for vacuum-tube rigs and within 10 percent for transistor finals.

On some rigs the voltage regulation is very poor and you might notice the energized voltage-channel LED changes under current peaks. In this case, the lower of the voltage LEDs shows actual voltage under load corresponding to the power input. Use the highest current LED and the lowest voltage LED to determine the intersection on the scale.

This write-up almost never got finished. The integrated circuits used (LM 3914) are much more fun to play with than to write about! As examples, they can be "chained" or put in series so that 20 or more instead of 10 LEDs can be used to better show the current or voltage. Expanded scales are also possible. If your rig uses about 500 volts, the LED voltmeter in the voltage channel can be set to show 10 or 20 points between 450 and 550 volts for better measurement resolution.

The display can be blinked or can trigger an alarm for over-voltage or over-current; black displays are possible, and either bar- or dot-display modes are available. For further information, you can look at the manufacturer's data sheets from National Semiconductor, and possibly others. ■

Diary of a Partially-Sighted Ham

Eyesight is not a black and white issue.
Here are some tips for hams in the grey area.

"Stand by a second; let me get my nose down to my S-meter and I'll give you a signal report."

As a partially-sighted ham, I've said this and several other standard phrases many times as I've gone to special lengths to operate my gear. Just for reference, my vision is rather limited. I am totally blind in my left eye and have about 20/400 vision in my right (that's with glasses; without them, forget it).

In amateur radio, as in everyday life, most people think of eyesight in a binary way: either a person has it or he doesn't. The issue of eyesight, however, is not black and white. It is, in fact, a continuum of greys. Partial vision can range from slight nearsightedness to resolution loss so severe that the person can read only foot-high letters at eight inches. Much has been written for the blind ham, and that is as it should be. I write here for the partially-sighted ham, the one who, even with glasses, cannot read easily, cannot drive, or cannot recognize people at any distance.

The partially-sighted, as a rule, do not like to be treated as though they were totally blind, because they are not. At the same time, they cannot function as a fully-sighted person, because they are not. Being an amateur with partial vision has presented some rather unique problems and some rather intriguing solutions.

There are five basic areas where the partially-sighted ham needs assistance: reading meters, reading frequencies, reading controls, logging, and QSLing. There are two methods for making these easier to deal with for the amateur with partial vision: Make it larger or make it brighter. Let's look at each of the areas of difficulty with these solutions in mind.

Reading Meters

It seems as though the entire hobby revolves around what any one of several meters reads. There are antenna-rotor meters, S-meters, swr meters, etc. With few exceptions, one must be able to read them to practice the hobby successfully. To read the meters on my Yaesu FT-101B and my rotor, I use a large five-cell flashlight, a police model equipped with a very bright beam. That extra illumination is enough for me to judge the relative position of the needles. If, however, I need an exact reading, I use magnification. At the Rand Corporation, about twelve years ago, Dr. Samuel Genensky developed a simple method for the partially-sighted person to get a lot of magnification at distances from six inches to many feet. This is useful if you cannot or don't want to get your nose right next to something. The idea is to take a small hand-held telescope or pair of binoculars and bring the focus much closer than it normally is. To do this, you simply place a positive lens over the objective end of the instrument. What I have done is take a Bushnell Minocular telescope, which is an 8×20, only four inches long, and mount a positive three diopter lens at the end.

I took the supplied lens cap and cut the entire top of it out, leaving just the sides and a one-eighth-inch lip at the top. I obtained a lens of the proper size from Edmund Scientific Co., glued it on the cap, and slid it over the end of the telescope. Now I have an eight-power telescope that is in sharp focus at seven inches. Exactly what the optometrist ordered. As you vary the power of the lens you place over the end of the scope, you change the distance where it comes into focus. I have another telescope that fits the same purpose; however, it is a ten-power and manufactured especially for the partially-sighted. This instrument focuses from nine inches to infinity with a very long-range focuser. It is available from Sam Walters Optical, 412 West Sixth Street, Los Angeles, California 90014, and costs about $75.

Back to meters. Using my scope I can read any meter as accurately as I need to. There is another way to read a meter—bring it closer. An swr meter with a remotable head is particularly useful.

Reading Frequencies

On my rig, with no digital readout, I use my flashlight or telescope. The newer digital rigs are of special advantage to the partially-sighted ham. With these there is no guesswork as to your frequency. The transceivers with green displays are more visible than ones with red digits. Green is much easier to see. Some of the digital rigs are also broadbanded; it

is wonderful because tuning up a radio is one of the more difficult tasks for the partially-sighted operator.

If your vision is bad and, like me, you are stuck with an older non-digital rig, you can use either more light or more magnification. Calibrating the radio accurately is a bit tricky, but with the telescope it is easily accomplished. I cannot emphasize enough the value the telescope with the add-on lens has been to me and many other visually-handicapped people I know. I strongly urge hams with visual difficulties to get one.

Reading Controls

Here the partially-sighted ham can come into his own. Any person with limited eyesight has had to memorize many different things that a normally-sighted person never thinks about. For instance, I have memorized the touchtone™ pad on my telephone. No big deal, you say. Well, I am the only person I know who can dial one without looking at the phone. If you have vision problems, you have probably already memorized all the controls on your radios. It's easy and a little operating time will let them into your mind. Again, the telescope or magnifying glass will make them large enough to see and memorize.

If you want to know the position of a rotary control, simply place a small piece of tape on the mark on the knob. This will allow you to feel the control's position without having to strain and look.

Logging

Thanks to the FCC's relaxed logging requirements, logging is not too difficult. You must always log all third-party traffic, though. What I did was get a printer to prepare me a pad of paper with very heavy lines that were spaced about three-quarters of an inch apart. They are ruled the long way on fourteen-inch paper. You may be able to use a regular log book, but if not, try this alternative.

This brings up reading and writing. There are a number of ways a partially-sighted amateur can write and read books and QSLs. The most inexpensive and easiest is to use a magnifying glass of some sort. I wear glasses, so I found a small jeweler's magnifier that fits over my glasses. It is eighteen power and allows me to read anything I want or need. Magnifiers come in a plethora of sizes and powers. The Jensen Tool Company of Mesa, Arizona, and US Business Specialties, 34848 Yucaipa Blvd., Yucaipa, California 92399, both carry a large line of jewelers' loupes for use with and without glasses.

Another key to logging and writing in general for the partially-sighted amateur is to use a writing instrument which produces writing you can see. I cannot see pencil writing at all and cannot see ball-point very well. The new generation of broad-line pens is just the item for us. Pens like the Flair, Pentel, and Pilot are heavy-lined and easy to see. If you still have difficulty, use a marking pen and have the printer make even wider lines on your log forms. It's nice to have the printer make up some forms for traffic handling, too. I cannot use the standard ARRL traffic forms, so I had one blown up four times as big. They are a bit cumbersome, but they get the job done.

QSLing

The problem a partially-sighted ham is most likely to run into with a QSL card is size. Most of the cards are just too small for you to write your information on the back if you write with large letters or use a heavy-lined pen. My solution was to get my local printer (he gets a lot of business from me, as you can guess) to make me some cards with large enough spaces to write in. The maximum size a card can be and go through the US Mail is 4.25" by 6". That's a pretty good sized card.

If you have a computer, you might get creative and have the computer place all the information on your card, leaving no writing for you. By the way, the telescope I mentioned earlier is perfect for reading a CRT or computer printout.

VHF and UHF

For the partially-sighted ham, VHF and UHF are a virtual snap. It is now rare to find a rig for these bands that doesn't have a digital readout. Beware, though, for some radios have automatic dimmers; if you get too close and cast a shadow over the display, it will dim, making it even harder to read. I've found that the best radios for two meters are those with separate controls for megahertz and hundreds and tens of kilohertz. With these you don't even have to see the display—just count the clicks! The radios with one-knob frequency control aren't as easy, but they still have clicks to count for the person who cannot easily see the display.

For the visually-handicapped ham, the hand-helds are a boon. Since we, for the most part, cannot drive, we don't have mobile rigs. Don't hesitate to use your HT in others' cars and on buses.

Speaking of HTs, some of the new synthesized ones are wonderful for the partially-sighted ham and others are a real pain. The ones with the LCD and LED displays are fine rigs (many features, etc.), but they are hard to read if you have low vision. Much easier, although with fewer functions, are the synthesized hand-helds with thumbwheel switches. Even though I cannot see the numbers on my Tempo S-5, I have no trouble dialing up frequencies by counting clicks (as long as I remember where I was when I started clicking).

Construction

I have only ventured into the areas of construction a little. There are some drawbacks to using a soldering iron an inch from your nose. I have found, however, that wire-wrap methods are quite useful and can be handled by someone with low vision. Dealing with high voltages can be a problem; if you are careful, *very careful*, you can handle the problem. The new digital multimeters are great for the partially-sighted ham. One other thing: Keep especially good tabs on polarities; if you mix up plus and minus with several hundred volts dc, you've got problems.

When it comes to construction, I have little real advice. I do very little but I know totally-blind *and* severely-handicapped hams who do a large amount of building. You must judge your own vision limits and act accordingly.

Conclusions

The world of amateur radio is particularly suited to the partially-sighted and blind. They cannot participate in other forms of entertainment as readily as those with normal vision. There is nothing wrong with their ears or voices, however. From AM to SSTV, the entire spectrum of ham radio is open to the partially-sighted ham. In emergency work, ARES, RACES, and with Red Cross, we make wonderful base stations. If you are partially-sighted and have been limiting yourself, stop it! Your only limit is what you make it.

If you know someone who has low vision, interest them in amateur radio; they will discover an entire world that they don't have to strain to see. ■

Hot-Spot Metering–Automatically!

Here are money-saving designs that will let one meter do the work of several. Keep in control and keep your change, too.

L. B. Cebik W4RNL
5015 Holston Hills Road
Knoxville TN 37914

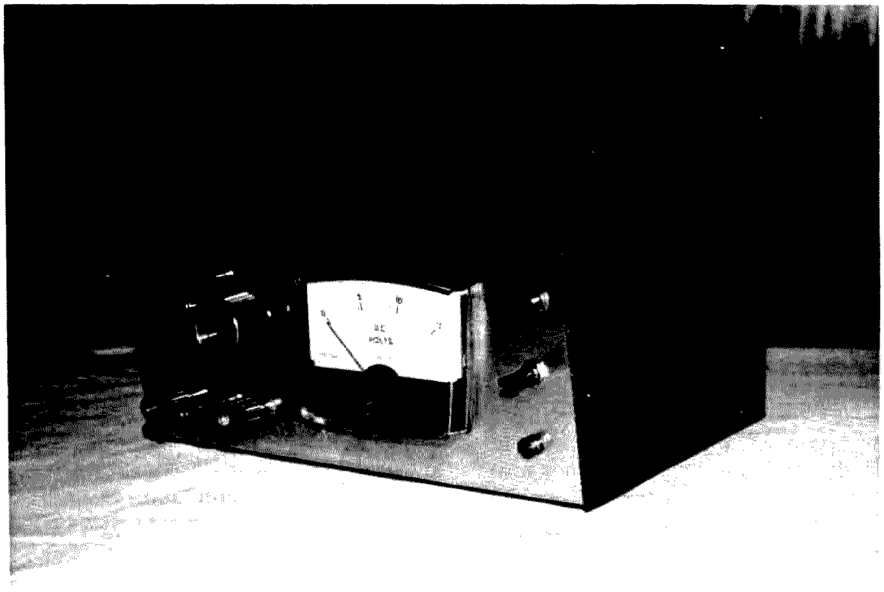
Metering is one of the best ways to monitor the operation of almost any piece of equipment in the shack. However, meters have two faults which have suppressed their use in home-brew ham gear: They are expensive and they are large. Even the least expensive panel meters cost eight to ten dollars each, and surplus meters in the correct range and size run as much or more. If that were not enough to cut down our use of them (and it is enough), meters also take up large areas of panel space. In this age of miniature electronics, we often do not want to waste space for just a few meters. There are a few lines of tiny meters, but they are hard to read.

There are compromises. We can, as do most equipment manufacturers, use one meter and manually switch functions. However, this option also has drawbacks. Ordinarily, we leave the meter set to register the most important value—relative output or plate current, for example—and we hardly ever look at the remaining values. Something can go very wrong inside a piece of equipment, and we might not know it until much too late.

If only we had a meter which could switch itself automatically from function to function, we could keep track of all parameters without raising a finger. We might also add a switch to lock the meter on a single reading in order to make adjustments. Ideally, when we returned the switch to Auto, the cycle would pick up where it left off. The circuit for accomplishing this trick should be fairly simple, or at least straightforward, so that we can adapt it to any number of devices we might build. But, alas, this is probably too much to ask of a circuit.

Automatic Meter Switching

In fact, the trick is easy to perform. With a combination of ICs—CMOS digital, linear, and op amp—and transistor switches, we can develop any number of switching schemes for meters. Fig. 1 shows in block form what we need. First, there is a clock to control the cycling period. Since we want to allow the meter needle to settle down so



An external view of the dual-voltage power supply shown in Fig. 2. The meter alternately reads the positive and negative voltages, while the LEDs to the right indicate which reading is on the meter scale. The switch between the LEDs permits the user to lock the meter onto the desired voltage.

that we can read the value clearly, something around 3 to 4 seconds per reading is desirable. We will need a pulse output to control the selector stage. On the whole, this looks like a job for the old reliable 555.

The second step is to select the metering circuit which will be read by the moving needle. Some form of a 1-of-N selection device or circuit will do the job. If we have only two values to monitor, a flip-flop would do. For more than two, there are selector chips such as the CMOS 4017 and 4022. I doubt that we would need more than 8 or 10 readings from one meter. In addition to selecting the circuit for the meter to read, this circuit should present the proper pulse to the next stage.

The next stage is a trigger for the transistor switches. At this point, we should be able to stop the cycle at any time for manually selected readings and then return to the automatic mode. These extra features may require one or two more chips, but the circuit design should not be difficult.

If we want to select voltages of opposite polarity, then the problems call for a slightly different technique. We will need to trigger switches that respond to different polarity voltages, and thus the standard high and low of digital ICs will not be the easiest route to follow. However, a digital output can drive an op amp to both positive and negative limits, and we can then use these pulses for our switches.

The final step is a series of transistor switches to connect the meter to the right metering circuit at the right time. The switches must be able to handle the voltages and currents involved, but there are techniques to keep these to a minimum so that a 1-milliamp meter can read almost anything we want to monitor. Also, we must ensure that one switch goes off before the next goes on, so that the meter sees one value at a time. Depending upon what we are monitoring, if the meter sees two values at once, we might end up with a bent needle, a fried meter, a blown fuse, or equipment destruction. Care in selecting our meter-switching circuits can overcome this potential problem. In some cases, we may also have to design some compensation into the circuit to cover slight losses in the transistors or in some other components. In most instances, these compensatory measures are simple.

In order to see these prin-

An interior view of the dual-voltage power supply. The power components are in the background, while the double strip of perfboard in the foreground contains the metering circuit. The forward board holds the ICs, while the second board contains the transistor switches. Construction is noncritical, and any convenient layout will work.

ciples at work, let's look at some actual circuits. Each has been tried and found useful in the shack.

One Meter for a Positive and Negative Bench Supply

Every ham workbench needs a dual power supply for testing or experimenting with op amps. The marketplace offers any number of matching positive and negative voltage regulators. A number of inexpensive kits (without meters) and partial kits are available. Thus, it makes sense to build this essential shack item. The problem is to find a way to meter both voltages to permit continuous monitoring and easy adjustment. Fig. 2 shows a way.

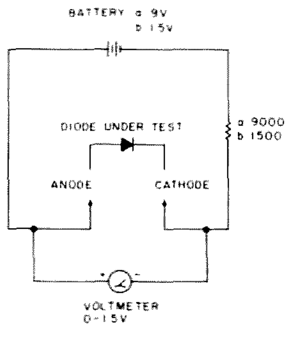

Fig. 3. A test circuit for matching diode forward-voltage drops.

The power-supply portion of the circuit, top, is a modified Jameco JE-215 semi-kit. It comes with a printed circuit board and most of the components we need for a bench supply. Switches, fuses, a case, and front-panel components are not included. The addition of the fuse and power switch are simple. Adding an off-board dual potentiometer was a bit more work.

The supply will provide 2 to 15 volts, positive and negative. The LM317T (positive) and LM337T (negative) adjustable regulators have a wider range, but the transformer (12.6 volts rms) limits the upper voltage to about 15, and then loading must be lighter than at lower voltages. For my purposes, the load capacities were correct, but I needed only a 5-to-15-volt range. The values for the labeled resistors, R1 through R9, were selected so that the dual pot tracks within a couple of tenths of a volt across the desired range. As a convenience for other builders, the method of combining calculations with test readings to obtain final values is described at the end of this article.

The metering circuit appears at the bottom of Fig. 2. It consists of a clock, a selector flip-flop, an op-amp switch trigger, a pair of two transistor switches, and the meter itself. As predicted, the clock is a 555, timed to give a brief positive pulse every 3.5 seconds. The diode across the 470k resistor allows the 15k resistor to control the positive pulse, while the off time is dependent upon discharging the 10-uF capacitor through the high-value resistor in this astable circuit.

The pulses clock the CD4013 D-type flip-flop, causing the Q and $\bar{Q}$ outputs to alternate, because the $\bar{Q}$ output is also connected back to the D input. Since there are two flip-flops per 4013 package, the unused section simply drives a pair of LEDs which flash according to whether the positive or negative voltage is being displayed on the meter. Normally, this circuit would ground the Set and Reset inputs of the selector flip-flop. However, we can use them to manually lock the meter on either the positive or negative voltage since they override clock pulses. Set drives the Q output high, while Reset drives $\bar{Q}$ high. Since CMOS can be grounded through fairly high value resistors, the 20k values shown keep the circuit in its automatic cycle until the SPDT center-off switch is flipped to one or the other of the lock positions. The LEDs will follow the manual readout as well as the automatic. When the switch is returned to center, the next pulse from the clock selects the other voltage and the cycle continues as if nothing had happened.

The op amp, a common 741, operates as a voltage comparator. Whichever input has the high drives the op-amp output to its full positive or negative value. The zeners in the input leads of the op amp limit the voltage, since only a distinct difference is needed to flip the op amp. The high-low contrast between the outputs of the 4013 more than suffices, and since they change together, proper comparator action would be guaranteed even if the difference were much less.

The op-amp output simultaneously feeds two switching circuits which are mirror images of each other. The 1N914 diodes at the first transistor bases eliminate opposite polarity excursions, hence the need for the 10k input resistors to the transistor switches. In fact, the switching circuits have been optimized on a breadboard to use the least current while still permitting clean switching with almost any replacement transistor. The transistors shown are available from numerous sources, but any 40-volt, 100-mA transistors will work. If there is a significant voltage drop across the output transistor for either circuit, decrease the base resistor of the output transistor (10k), then reduce the collector resistor of the input transistor (33k), or try another output transistor.

Using a two-transistor switch for each of the voltages is necessary. First, op-amp output voltages often do not rise to the level of the supply voltage. However, if the output transistors are to be cut off, the base voltage must be very close to the supply voltage. Using an input transistor switch solves this problem. Second, the meter must be isolated from the line by the switch, and one switch must be off before the other comes on. This circuit achieves both results with relative simplicity.

The meter itself appears to be connected across the collectors of the output transistors. However, the diodes to ground complete

the voltage-reading circuit for each of the supplies. Thus, you can think of the meter as being in two separate circuits which do not interact. The 1N4001 diodes do introduce between .5 and .6 volts error in the meter reading. To correct this, we might design a complex compensating circuit. In this case, simplicity is serendipity. The 1N4001 diodes in the power-supply output, forward-biased, lower the voltage by just the same amount so that the meter is accurate with respect to the voltage reaching the outside world. Since small power diodes (anything with a 50 piv rating will do) are available at many for a dollar, matching four within a tenth of a volt is easy. Fig. 3 shows a test circuit for doing this job, although many new DVMs have a special resistance position that will reveal the forward drop of diodes.

The circuit is adaptable to many other applications. The ICs will all operate with supply voltages from 5 to 15 volts (positive and negative for the op amp only). Fig. 4 shows three different ways to power the circuit. The scheme labeled (a) was used in this supply, its only negative aspect being that the brightness of the tracking LEDs changes with the supply voltage. For voltages higher than 15 or lower than 5, (b) and (c) show ways to tap unregulated voltage and use zeners to supply the ICs. For voltage limits between 15 and 18, (b) is convenient, requiring one less zener diode. All the ICs in this application draw negligible current, allowing fairly high values for the zener dropping resistors. Since only the switches need to see the actual supply voltage, you can run the ICs at any value recommended in the spec sheets. If the op-amp output voltage runs too far above the supply voltage to the input

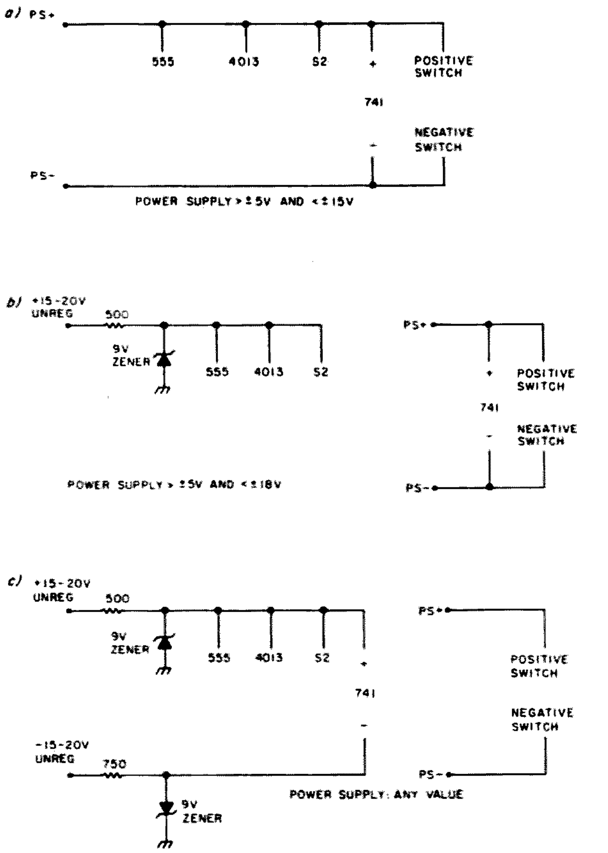

Fig. 4. Three methods of supplying power to the meter-switching circuit.

transistor in each switch, a zener at that point will limit the voltage and hence the base current.

Construction is noncritical. The photograph of the supply shows the use of two strips of perfboard—one for the ICs, the other for the transistors. T46 vector pins hold the boards together, with insulation material between. Besides its compactness and the fact that I was able to use up some scraps of perfboard, there is nothing in particular to recommend this form of construction. However, note that not only are the ICs in sockets, but so too are the transistors. Eight-pin IC sockets work very well for low-current pairs of switching transistors.

One Meter for Many Readings

In order to switch more than two voltages, we need to change techniques somewhat. Fig. 5 shows a circuit for handling up to eight voltage readings on one meter. Despite appearances to the contrary, the circuit is similar to the earlier one. We begin with a 555 clock to provide counting pulses at 3.5-second intervals. Instead of using a flip-flop as our selector, we insert a CD4022 one-of-eight selector. This counter is simply a string of flip-flops, the output of each coming on in turn and going off as the next one comes on. If we need fewer than eight readings, then we cut the count short. Suppose, as in the schematic, we need 4 readings. We use outputs 0 to 3 to turn on the switches. Output 4 is coupled to the Reset pin via a capacitor. The very brief pulse returns the counter to output 0 (our first reading) without any significant delay or meter needle lag. For some other interesting switching possibilities, see WA2FPT's "No More Rotary Switches" (*73*, September, 1979, p. 118).

Between the 4022 and the switches, we insert a hex buffer, the CD4503. We need this device in order to be able to lock the meter manually in case we wish to make adjustments. The 4503 is a tri-state device; that is, it acts as a normal buffer when the Enable pin is low. When the pin is high, the buffer outputs are effectively open circuits (more correctly, very high impedance circuits), unaffected by and not affecting anything else on the output lines. This is ideal for manual switching. We place a high on the Enable pin and simultaneously turn on the desired switch so that the meter reads the desired voltage. At the same time, we also place a high on the clock Enable pin of the 4022, which locks its output wherever it last was. Then, when we return the switch to the Auto position, the readout cycle picks up just where it left off.

Note that the clock pulse is guided to the 4503 Enable pin through a diode (and is isolated from the 4022 Enable pin by another diode). The function of this system is to ensure that one switch goes off before the next comes on. The delay is of the order of .1 second, so that the meter needle drops about a third of the scale before rising to the next measurement. By reducing the 15k resistor in the 555 clock circuit (about 2k minimum), we can reduce the pause almost to the point where the needle will not react to it. However, we do preserve meter isolation as we move from voltage to voltage.

Because there are no usable leftover IC sections, we have to add a hex buff-

YOUR SICK RADIO NEEDS US!

We're the High Technology Service Center and we specialize in 2-Meter FM transceiver repair. We have the expertise, trained staff, and equipment for this because we have been the national authorized warranty and non-warranty Azden service center for many years now. But now, for the first time ever, our service facilities are open to other brands of 2-Meter FM transceivers. Our expert staff of trained technicians have been trained to service the models specified below, and all major replacement parts for these models are now in stock. So don't hesitate to make your sick radio better. Send it to the specialists - High Technology Service Center.

Models we are now accepting

Kenwood	Yeasu
TR7400	FT-227R
TR7730	
ICOM	KDK
IC-2	FM2016
IC-25A	FM2025
IC-255A	

Service Rates

First hour is $39.00. Each additional hour is $29.00. Shipping and parts are additional. Radios with common component failure will not exceed one hour. Radios that we cannot find a problem with will be subject to a ten dollar charge to cover the extensive testing we will perform to try to make the problem show up. All repairs will receive a 90 day warranty on work performed. We reserve the right to refuse any repair for any reason at no charge to you.

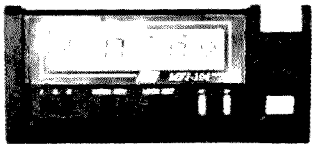
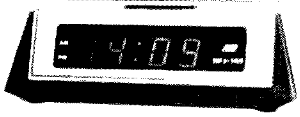
MFJ 24 HOUR CLOCKS

Your choice: dual 24 hour LCD display, or 24/12 hour with ID timor, or 12 inch quartz analog.



$39.95 DUAL 24 HOUR LCD MFJ-104

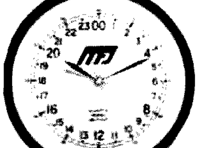
Two independant 24 hour LCD displays! Read both GMT and local times at a glance.
Six digit main display has seconds readout. Four digit auxiliary. Switch reverses main/aux.
Alarm plays 4 selectable melodies. Alarm "ON" indicator. Snooze button.
Quartz timing. Synchronizable to WWV.
Flip-top cover serves as stand.
Night light. Forward/reverse, fast/slow set buttons. Lock function prevents mis-setting. Display main time only, main/auxiliary or main/alarm time. Includes battery. 4x2x1/2 inches.



24/12 HOUR, ID TIMER MFJ-102 **$32.95**

Switchable 24 hour GMT or 12 hour format.
ID timer sounds every 9 minutes after reset.
Switchable seconds readout.
Observed timer. Just start clock from zero and note time of event up to 24 hours.
Bright blue 0.6" vacuum fluorescent digits.
Alarm with snooze function. Synchronizable with WWV. Fast/slow set buttons. Lock function prevents mis-setting. Power out, alarm "ON" indicators. 110 VAC, 60 Hz (50 Hz with simple modification). UL approved.
Black, brushed aluminum top/front. 6x2x3".

24 HOUR QUARTZ MFJ-105 **$49.95**



True 24 hour quartz wall clock has huge 12 inch diameter face. Gives excellent visability across computer /radio room.
Fifteen seconds per month accuracy.
Single "AA" battery provides over one year operation, immunity from power line failure and eliminates power cord.
Sweep second hand. Brown hi-impact case. Glass front. 24 hour military time format.

The four-meter switching circuit of Fig. 5 is shown in a test configuration prior to installation. For initial testing, the four transistor switches along the bottom of the board are all connected to the test supply line, and temporarily mounted LEDs in the upper right corner (later to go on the front panel) indicate which parameter is being measured. T46 pins provide convenient points for final assembly.

er, the CD4049, to drive indicator LEDs. The inputs can be connected to the 4503 output lines since the input requirements do not appreciably load the sources. However, if the supply voltage is at or above 10 volts, add a current-limiting resistor to the LED line, scaling it from 500 to 1k for voltages from 10 to 15. For voltages under 10, the IC provides sufficient current-limiting. In this circuit, all voltages between 5 and 15 will provide equal performance, so that any convenient tap with an isolating resistor and a zener diode (say about 9 volts) will power everything. The switches, of course, will be powered by the voltage being read.

The switching circuits for each line are the same. If the voltages vary widely, you may wish to optimize the resistor values on a breadboard before building a final unit. If the voltages vary by as much as 10 to 1 or more, then you may want to add multiplier resistors to the meter. Most voltmeters are simple microammeters or milliammeters with a series resistor to limit the current to the full-scale meter value at the highest value of voltage to be read. Since they are more common and cheaper, let's assume we start with a 1-mA meter. If our basic voltage range is 10 volts, then we would add a 10k resistor in series with the meter according to the formula R=Ef/Af, where Ef is the desired full-scale voltage and Af is the full-scale limit of the meter, all in basic units. Thus, our desired 10 volts divided by 1 mA (.001 A) yields 10,000 Ohms.

Suppose one of our readings requires a 100-volt scale. To calculate the required multiplier to insert at any of the "x" points in Fig. 5, we can use the formula Rm=(Ef/Af)−R, where Ef is our new full-scale voltage, Af is the current full-scale reading, R is the series resistor we just put in place, and Rm is the new multiplier. If we divide 100 volts by 1 mA, we get 100,000 Ohms. However, we already have 10k in the circuit, so the extra multiplier in the collector circuit will be 990,000 Ohms, or the closest catalog value we can find. The closer the tolerance resistor we can obtain, the better. One-percent resistors are used in VOMs; for our purposes, a close value culled with an accurate resistance meter from a batch of 5% resistors will usually be good enough. If the multiplier is a variable PC board trimmer, then the value can be set to compensate for any voltage drop across the transistor, and the basic resistor in the voltmeter circuit can also be made variable. Some quick tests with a well-calibrated VTVM will permit you to optimize the circuit readily.

In this all-positive circuit, there is no need for guiding diodes to complete the meter circuit. Since the switching output transistors isolate the meter from the voltages except when one is conducting, the meter will see no more than a single voltage at a time. The circuit can be modified further for current readings; however, this requires switching isolation at both terminals of the meter, which adds complexity to the circuit. Identical switches controlled by the single selector or trigger IC will function with appropriate shunts to bypass the operating current. In fact, we can make the circuit about as fancy as we wish. How cost-effective this technique is will be a function of how many panel meters we save in the process.

Multiple Positive and Negative Readings

The selection system used in Fig. 5 can be adapted to a mixture of positive

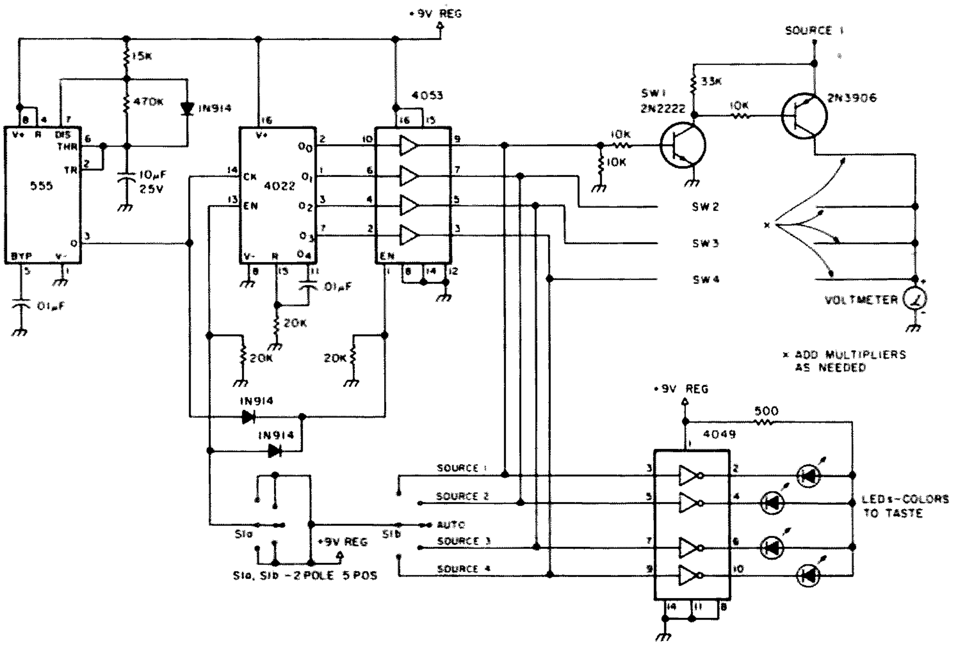

Fig. 5. Circuit for switching several meter readings automatically.

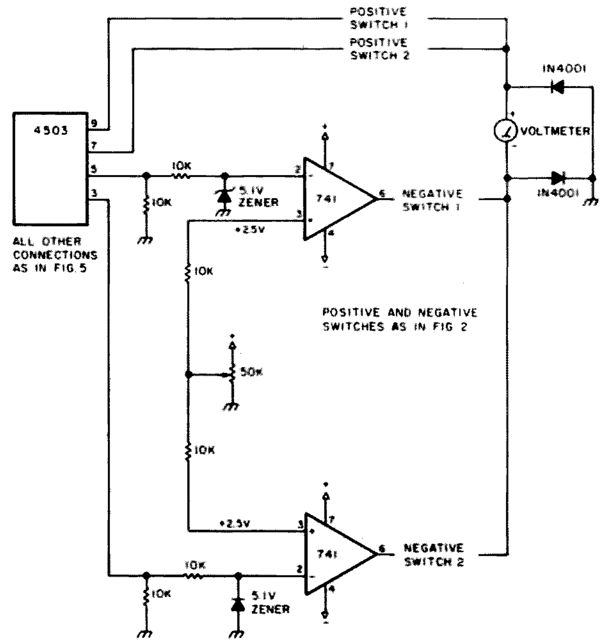

Fig. 6. Revisions to Fig. 5 for multiple positive and negative readings.

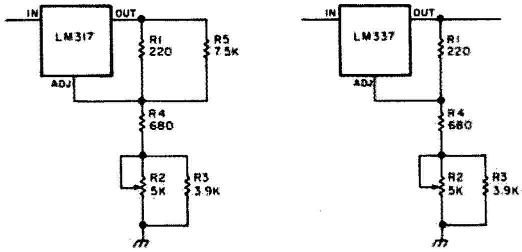

Fig. 8. LM317/LM337 control circuits with range limit and tracking adjustments.

and negative readings by the addition of op amps and guiding diodes. Fig. 6 provides the details of what we need to add. Assume that we have two negative readings to take in addition to a couple of positive ones. A pair of 741s solves the problem. Since we do not have a flip-flop to provide automatic output reversal, we provide the positive input of the op amp with a reference voltage. It should be about half the supply voltage, although 2.5 volts positive will handle almost any supply voltage. When the 4503 output goes positive, driving the inverting input, the op amp swings negative. It drives a negative switch identical to the one in the power-supply circuit, with a 1N914 at the transistor base to limit the positive swing at that point. Of course, we provide the op amp with positive and negative supplies, tapped and regulated from some convenient circuit point. The only other addition to the circuit is the diodes at the meter to provide isolated completion to the meter circuit.

Since, once again, there is a definite diode voltage drop to make readings inaccurate by that amount, we need compensation. If the trick in the power supply is not applicable (for example, if we are metering the voltage in circuits within a piece of equipment), then variable multipliers may be the best means to make readings accurate over the region of the scale of most concern to us.

A Note On Tracking Power-Supply Voltages

As promised earlier in the article, here are some notes on getting positive and negative supplies to track with common components available from sources such as Radio Shack. Fixed resistors are rarely a problem because we can find matched pairs with an ohmmeter. The problem lies with dual potentiometers that may be readily available. They may vary by up to 10 percent from section to section. But we can compensate. Fig. 7 shows the positive and negative control circuits recommended for the LM317 and LM337 regulators. The values shown for R1 and R2 in each case call for either a 1k or a 2k pot in the variable part of the circuit. Dual 1k pots do exist, and if you have one, then your problem is solved, assuming you wish the regulator voltage to go down below 5 volts.

Fig. 8 shows the requisite circuit in my case, which called for R3 to limit the low voltage and R4 to parallel the potentiometer. Here is how to proceed through the problem, calculating and measuring your way to final values. The manual covering the regulators provides this formula for determining output voltage: $V_o = 1.25\,(1 + R2/R1)$, where R1 and R2 are the components shown in Fig. 7. If we assume that R1 will be 240 Ohms (we will calculate an actual value shortly), then we can solve for R2 at the 5-volt lower limit of the supply. $R2 = R1(V_o - 1.25)/1.25$, or 720 Ohms. At 15 volts, the upper limit of my supply, R2 would be 2640 Ohms. A slight compromise of using a 680-Ohm resistor at R3 would permit use of a 2k pot to vary the voltage from just under 5 volts to just over 15 volts.

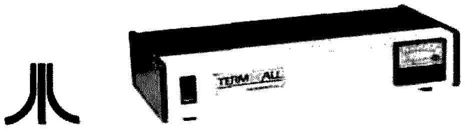
To find a 2k dual pot is nearly impossible when you are in a hurry. However, dual 5k audio pots are common, and a parallel resistor will bring them to 2k without spreading or contracting the ends of the scale too radically. Since manuals always print the parallel resistor formula in terms of Rt and never in terms of the resistor you need to put with what you have to achieve a desired value, here it is: $R_p = (R_t \times R_g)/(R_g - R_t)$, where Rg is the resistor you have, Rt is the total parallel resistance desired, and Rp is the value to be placed in parallel with Rg. The value we need to convert the 5k pot into a 2k pot is 3.3k.

Remember, however, that the pot sections will not be very accurate. Measurements forced me to use 3.9k resistors. The two sections of series-parallel combinations had ranges of 688 to 2756 Ohms and 699 to 2819 Ohms respectively. Using 688 Ohms as the lowest value with 5 volts output, the next calculation was R1.

$R1 = 1.25\ R2/(V_o - 1.25)$, or 229 Ohms, with the values given. 220-Ohm resistors for R1 were the obvious trial choices. In measuring values on hand, a slightly low value was used with the

TERMINALL

NOW FOR ATARI* 400/800



SEND & RECEIVE CW & RTTY

TERMINALL T4 is a hardware and software system which converts your Atari Computer into a state of the art communications terminal.

- TERMINALL is easy to use. Plug into your receiver headphone jack and copy Morse code or radioteletype. Plug into your CW key jack and send Morse code. Attach a microphone connector and send Baudot or ASCII using audio tones (AFSK). That's all there is to hooking it up.
- Fantastic Morse reception. No adjustments are necessary to receive Morse code. It's fully automatic! Six stage active filter demodulator and auto adaptive Morse algorithm copies the weak and sloppy ones.
- Separate RTTY and CW demodulators, built in crystal controlled AFSK, CW and PTT keying, 60 mil loop interconnect, RS232 IN and OUT, hand key input and side tone output.
- Cursor Editing - use cursor control keys to insert, delete and write over any text in all buffers (break, message and history).
- Save to Disk - full save to disk or cassette capabilities. TERMINALL files are compatible with many word processors including Text Wizard*
- Built in parallel printer driver software
- Multiple user defined WRU functions. You select initiate sequence, terminate sequence, what to transmit back and whether to save on tape or disk.
- Word wrapping, word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, auto adaptive transmit delay, break mode and more.
- Complete with software on diskette, and cassette, assembled and tested hardware, and extensive instruction manual.
- 15 day money back trial period on factory direct orders. One year limited parts and labor warranty.

Call or write for details.

688-Ohm circuit and a slightly high value was used with the 699-Ohm circuit. Since the output voltage is a function of the ratio of R1 and R2 in Fig. 8, this move tended to stabilize the ratio.

Upon wiring the circuit, one voltage was slightly above the other. Resistors with values in the 5k to 10k range were soldered in parallel with R1 in the lower voltage circuit, increasing its output. The 7.5k value provided tracking within a couple of tenths of a volt across the range.

Although the procedure sounds difficult, a hand calculator makes the calculations simple. Breadboard resistance measurements are quick with an accurate ohmmeter. Only the final parallel resistor was added after construction and testing. The entire procedure took about an hour, and some of that time was devoted to converting the formulas and to scrounging in the parts bins. A little extrapolation will permit you to design for any range you wish (within limits of the regulators, of course). Since most regulators have formulas similar in form, although different in detail, to the ones used here, these notes may help you custom design your own supply rather than accepting only what is offered on the market.

Combined with the meter-switching circuits, the article may help save you some money and space, since together these ideas provide a foundation for a compact bench supply that still offers complete control and monitoring. The circuits, of course, have a wide potential for application to other projects. They fit about anywhere you need to know several voltages, whether high or low, positive or negative, or all of the above. ■

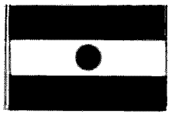
73 INTERNATIONAL

Each month, 73 brings you amateur radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73: Amateur Radio's Technical Journal, *Pine Street, Peterborough NH 03458, USA, Attn: Avery L. Jenkins WB8JLG.*



INDIA

DX George tunes in the 40-meter ham band—he hears a local SSB rag-chew in progress. The next moment he hears a QSL in AM followed by a CW ham happily thumping through the progressive conversations. The round-robin mixed-mode net goes on merrily for hours. This must be VU2-land. Nowhere else on Earth will you find such an accommodative ham spirit of coexistence with World War II surplus equipment alongside the latest ham gear of Kenwood, Yaesu, Icom, and home-brew QRP transistor transmitters with modified broadcast transistor receivers—ham spirit to the core! Hi!

The latest Indian callbook accounts for 1,300 callsigns including 45 club stations. Considering a population of 700 million, each callsign holder represents over half a million people. Seventy-five percent of the hams are in the cities like Bangalore, Bombay, Calcutta, Delhi, Hyderabad, and Madras. The remaining hams are spread over the country. Of these, only about 300 have multiband equipment, and it is mostly for CW operation. A few have been able to acquire modern transceiver rigs providing SSB operation—and those are the stations that are heard overseas on SSB.

The CW stations use the surplus and disposal equipment or use home-brew rigs made out of components of disposal equipment. The receivers will be of the type AR-88 (RCA), SX-28, BC-779, HRO, R-1155, etc. The aircraft receivers of the BC-348 series also are used, suitably modified for mains operation. The transmitter is invariably home brew, using an 807/1625 final. The power is limited to 100 Watts.

These surplus bargains are no longer available, so the younger generation of hams has to look for transistors and ICs for home brewing. While technical know-how is available for home brewing, poor availability of suitable components and cost are the limiting factors. Club stations and many of the old-timers help SWLs get started with licenses and rigs.

There are two types of licenses—Grade I and Grade II. The Grade I license requires a 12-wpm Morse speed as against 4 wpm for Grade II. Both grades must also pass a theory test. Initially, only CW operation is allowed. The license-issuing authority is "Wireless Adviser to Government of India, Ministry of Communication," located at New Delhi. The examination fee is Rs. 15/—($2.00) and license fee for two years is Rs. 40/—($5.00).

There are two major organizations which look after hams' interests: the Amateur Radio Society of India (ARSI) and the Federation of Amateur Radio Societies of India (FARSI). The only ham magazine, *Radio*, is published by FARSI and contains articles of interest reprinted from ham magazines elsewhere in the world, like *QST*, *73*, *CQ*, etc., in addition to covering local news.

Gaining experience and equipment, Indian hams are breaking new ground in national service. They handled emergency communications during the Morvi disaster in Gujarat State. They provide base station and mobile communications for the 4000-km Himalayan rally and the Mysore Safari every year during November/December. They take part in the International Scout Jamboree, which spreads ham activities to the younger generations. They carry their stations to schools and enable children to speak and listen on the ham net all over the world; they create awareness and interest that may germinate and grow in the future.

The Andhra Pradesh Amateur Radio Society (APARS) is the only organization which has received government support. The state of Andhra Pradesh has a large coastline in the east similar to the US Florida coast, subject to heavy cyclonic weather every year. To provide information and communications in emergencies, the AP government has joined hands with the hams and they are in the process of establishing a number of communications networks long the east coast of India. This is a pioneering venture of a state government which may prove fruitful and can pay itself off during a single bout of cyclonic weather.

In spite of many hurdles and limitations, the meager ham population proudly includes veterans who were licensed before 1920—and also stations communicating through OSCAR and tracking other satellites. It is a wide contrast and a difficult point for overseas hams to understand—that with few facilities and finances, these hams are propagating the ham spirit as well as sustaining ham activities.

ADVENTURE AND QSOING FROM BY-LAND

It goes without saying that the BY call is in one of the rare DX areas! But to be able to make the trip into China and have the BY next to our own call as a portable or mobile seems almost too good to be true. It was not, however, for Robin Maule VS6HH (formerly G3OEF and 9V1RR), who last February realized this dream. He is probably the first and only foreign ham operator since 1949 to have an authorized portable/mobile BY attached to his call.

Maule works in Hong Kong as sales manager for East Asia, with Motorola, Inc., and worked with the Hong Kong Motor Association which sponsored and was chiefly responsible for the international car rally from Hong Kong, going all the way to Peking, China. This event took place early last month. There were a lot of taxing preparations for this "first" in China, and one was desperately-needed radio communications. Robin was able to lend a helping hand on more than one occasion.

One such time was 8:00 am (local time) Sunday, February 20, 1983, at the New World Hotel in Kowloon, Hong Kong. Here, the caravan of one mini-bus and two cars led by Phil Taylor of the H. K. Automobile Assocation, with Robin and a team of eleven others, began the dry-run trip to Peking.

The Radio Sports Federation of China and the China Ministry of Tele-Communications approved the granting of the BY portable/mobile call to Robin. Four frequencies were requested on SSB, two on 40 meters, two on 20 meters, and one VHF frequency. Although this was not a DXpedition but a final route trial for the rally, VS6HH was able to operate. As Robin said when I interviewed him, "It was not within our mandate to work DX." So only traffic related to the rally or greetings to families of the rally team and members in H.K. were allowed. The correspondents from Japan likewise sent some greetings home.

At 10:00 am, the group crossed into China. They missed their first radio schedule since they were going through customs and immigration. They were met by the Deputy of the Chinese Police, officials from Chinese Public Security, many interpreters, several press agencies, and a Chinese TV crew which made video recordings.

They had to take along their own fuel and other supplies. Robin said that the speed limit in China was 40 mph, but the police escort sailed down the highway with red lights flashing, flags waving, and sirens sounding at a jaunty 60 mph!

The next schedule was with Ed Nance VS6DX and Phil Weaver VS6CT at 3:00 pm local time. Robin had a Motorola (of course) Micom S, 100-Watt synthesized SSB, and used a mobile antenna. Contact was made on both 7075 and 14.160 MHz. You are right! There were two very jubilant DXers in Hong Kong as well as one very happy VS6HH/BY in China.

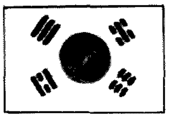
At times, the road was dark with mud up to the axles, but the scenery along the way was incredible. Robin said it was a unique experience to find oneself at night, in a strange place, in the rain, at an unknown QTH, hanging up a dipole antenna! L. S. Drakeford VS6EK, as well as JH1UGN and JH1IED, likewise made contact and had a good QSO with this rare call station!

Robin accompanied the trial-run group as far as the city of Wu Han. On February 25th, he flew back to Hong Kong. However, the remainder of the team continued to drive to Peking. This was probably only the second time a group of Westerners had been permitted to drive that route. (First time was last year.) At each village, the group passed by several hundred people lining the road who surrounded the vehicles when they stopped.

Robin declared, "The scenery was fantastic with gorges—cliffs below and high mountains above as we made the journey through Canton, Hunan, and Hubei provinces, with Hubei province being the most spectacular."

Another first in the episode, besides the rally, was Westerners traveling by car with the authorization to use SSB for the first time since the "liberation" in 1949.

Crossing into Hunan from Guangzhou Province, escorts hand over the caravan (VS6HH/BY in center).



KOREA

Michael Wengert KH2AC/HL
CPO Box 2961
Seoul, Korea

Thirty years after the cessation of hostilities on the Korean peninsula, the United States military still maintains upwards of 75,000 troops, civilians, and dependents in South Korea. Although the Republic of Korea has no reciprocal amateur radio licensing agreement with any country, certain foreign personnel are allowed to operate their ham stations here. The Korean government has allocated a fixed number of amateur radio sta-

tions to US military personnel stationed here, and, although it is not published, the number is believed to be 55. Licensing of the HL9-prefix stations is handled by the J-6 Office at the Frequency Coordination Office at the Eighth US Army garrison at Yongsan, in Seoul.

Unfortunately, as 1983 opened we found an actual decrease in ham activity in Korea amoung HL9 stations. The reason: Due to the increase in the number of military personnel stationed in Korea, roughly 90 percent of them must live off base, in housing in the Korean civilian community. So due to the recent enforcement of a long-ignored qualification by the J-6 Office that HL9 operation must take place from inside a US base, most of the hams, especially in the Seoul area, have found themselves involuntarily QRT. Since I neither live in a military compound nor am connected directly with the military, I am also off the air.

A recent check with the Korean Amateur Radio League indicated that they were not particularly interested in pursuing reciprocal licensing at this time. This would seem the best way to solve the licensing problems in Korea, but it seems to be impossible to hurry things in the East. Perhaps when a larger number of Koreans are permitted to visit foreign countries and the percentage of hams among them becomes greater, we might find some interest on the Korean side for reciprocal licensing.

The main theme of the column this month, then, might be a warning not to expect to hear too much from HL9 stations in the near future. But activities by HL1-5 stations is on the upswing. The Korean government seems positively behind the expansion of amateur radio in Korea as a sort of PR operation in light of the Asian Games to be held in Seoul in 1986 and the Olympics in 1988.

More on these and other topics next month. 73 from the Land of the Morning Calm.

TAIWAN

Tim Chen BV2A/BV2B
PO Box 30-547
Taipei, Taiwan
Republic of China

Some hams who have frequently visited Taipei and BV2A/BV2B are W9ZNY, N5RM, G4KLP, KA8LGX, JA1AN, JA1EBM, W6PN, VS6DD, N9BBQ, and W2NSD. All of them have business and personal connections in Taiwan and have an eyeball QSO with Tim Chen upon almost every arrival. K7UGA also was greeted by BV2A four times in the past few years.

By statistics, I have so far met ham friends from the US mainland, Canada, Panama, Venezuela, Colombia, Peru, Brazil, New Zealand, Australia, Vanuato (Solomon Island), Guam, Hawaii, Saipan, the Philippines, Singapore, Indonesia, Malaysia, Hong Kong, Macao, Thailand, India, Israel, Nepal, Jordan, Korea, Japan, France, Italy, England, Switzerland, Germany, Belgium, and South Africa.

W6BIP, K6IR, K4XH, K2CM, W2AMS, WA3HUP, W2IYX, JA2MTO, JG1QGT, 9V1RH/VK3QV, and JM1UXU have had frequent exchanges of letters with me to discuss RFI, QSLing, OT stories, and regional matters.

W7PHO, W6RGQ, WA7ZTL, VS6CT, and AH2G are met on the air from time to time, but the currently poor propagation is causing me to miss all the fellows who used to check in with the Family Hours Net maintained by Bill W7PHO and his associates. I occasionally check in on the SEANET hour at 1200Z Wednesdays on 14320.

Bob Mitchell N5RM and his XYL visited Taipei before the Chinese Lunar New Year holiday and dined with the Chens at the Grand Hotel, one of the ten best in the world. We exchanged personal gifts to mark the special occasion. Besides them, the president of Air Asia was also present; he was very delighted to know about the unique friendship and activities of the world's radio amateurs.

Since my retirement, I have been able to make more schedules on the air. Those who want my QSL for DXCC will have more chances. But owing to construction of iron work on my roof, I am suffering from surrounding obstacles, especially toward the direction of the States.

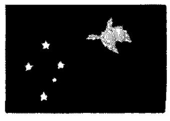
Frank W9ZNY is now in Taipei and is going to lend a hand in this matter, hopefully, to raise my present antennas higher for better radiation. Long-path QSOs with the US east coast are frequently open at around 1130-1330Z. I have just received an award from the South Florida DX Association. Also, try for possible US QSOs 0000-0200Z, Sundays, on 21030 or 28530.

Many enquiries are being received questioning the possibility of obtaining a temporary license and TTY operation, etc., on Taiwan. There is nothing happening with these concerns until local hams have been granted more station and operator licenses.

Regretfully, someone claimed a lost QSL via a post office box, and the International Lions Club lost a trophy which had been sent by air parcel. I have contacted the Postmaster and learned that some mail has been misrouted but sent back later.

Only Japanese IRCs are exchangable at the Chinese post office. Occasionally other IRCs are exchanged with some philatelics—who do not accept old ones exceeding two years. CRA BV QSL Bureau is to answer QSLs; it used to return 2 IRCs as reciprocal upon receiving a green stamp. If obtainable, Chinese mint stamps seem more convenient.

Noticing that the 1983 *Callbook* has deleted the BV Bureau from the QSL Bureau page, may I ask that all direct QSLs (except via QSL managers) be forwarded to my address (above) for handling, please.



PAPUA NEW GUINEA

Siegi Freymadl P29NSF
PO Box 165
Rabaul
Papua New Guinea

Hello there and greetings to everyone from Papua New Guinea, and especially from the Island of New Britain. The 10m band appears to have recovered and I have had a great time working into the United States. It is amazing how many hams tell me that they know my QTH as they were here during the campaign in the Pacific in World War II. In those days, communications played a very important role, as the coastwatchers maintained observation over occupied areas and passed the information to Allied Headquarters for action. Rabaul was the Headquarters of the Japanese Navy then.

I have just received updated information on the number of licensed amateurs in PNG. There are 93 full calls, 22 limited calls, and 36 Novice calls, giving a total of 151. About 10 of these would be YL operators. The ranks of hams may be swelled when new callsigns are allocated as a result of the AOCP exams held in February—we can expect to hear several new operators from the North Solomons Province.

As of January, 1983, all full-call amateurs in P29 can operate the new 10-MHz band in line with VK. The Papua New Guinea Amateur Radio Society (PNGARS) has written to Radio Branch concerning allocation of the 10- and 24-MHz bands for full-call operators; these also are available to VK amateurs.

VHF activity: P29ZUK, P29QA, P29ZSS, P29ZTD, and P29ZFD are active on 6m. P29SS hopes to be active soon on 6m, SSB, and CW, upon completion of a beam. P29ZUK, P29ZTD, P29ZSS, and P29LW operate on 2m and 70cm, and P29ZSS is also on 1296 MHz.

There are two beacons in Port Moresby, a 6m beacon (P29SIX on 52.013 MHz) and a 2m beacon (P29TWO on 144.030 MHz).

On the repeater scene, the Port Moresby repeater is operational. The planned repeater on the border of the Northern and the Central Province will be ready for testing in Port Moresby before you read this. When finally installed on site, on the eastern dome of Mt. Albert Edward at an altitude of 13,000 feet, it will be the highest repeater in the southern hemisphere and possibly the highest in the world. Equipment is Philips FM-828; the transmit frequency is 146.650 MHz and the receive frequency is 146.050 MHz. Power source: three Solarex 2-Amp, 12-V solar panels, two 105-Amp/hour batteries. Antenna: AEA Isopole, 5-dB gain.

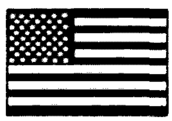
The planned North Solomons repeater (P29RBI) is being tested at Arawa. Transmit frequency, 147.0 MHz; receive, 146.400 MHz. The equipment is a modified Philips FM-828. There are three possible sites under review, two of the sites being on the coast and one high up in the mountains. The latter would bring the repeater in line-of-sight with Mt. Albert Edward (about 900 km away), but there are fears that the repeater could be vandalized at this location.

Information has come to hand about the North Solomons Amateur Radio Society. North Solomons Province, on the island of Bougainville, is one of the most active provinces in P29, amateur-wise. Most of the operators there are employed at the giant copper mine, Bougainville Copper Limited. Gatherings of the North Solomons Amateur Radio Society are held every 4 to 5 weeks at the Panguna Mine site. Bougainville Copper Limited obliges with luncheon provided in the mess, and OMs P29BG, P29QA, P29TE, P29NJW (P29ZSO), P29NML, P29NES, and YL P29NJF get together with other interested people.

Also at Panguna is Jenny VK4NIY who hopes to upgrade and receive a P29 full call, and VK4VAU, a 12-year-old student who is too young to receive a P29 license. It appears that one has to be at least 15 years old to receive an amateur license in P29!

The Radio Society also holds social outings every two months or so. The North Solomons Amateur Radio Society is in the process of affiliating with the PNGARS. A very active group, that! John P29JM from Panguna is also one of the net controllers of the Inter Island Net which operates every day on 14.315 MHz at 0800Z. Other net controllers are Tom KX6QU on Kwajalein, Bud KN6GJN and Gus AH6DR on Hawaii, and Mel KG6JHH on Guam. The net handles 2nd- and 3rd-party traffic, emergency traffic, and marine traffic, and thereby fills an important need.

Another province with a fairly large amateur population is the Eastern Highlands Province. As previously mentioned, the Highlands provinces even have their own net on 80m. At Ukarumpa in the Eastern Highlands, we have the Summer Institute of Linguistics with about 500 members, and in their ranks are a number of active hams: P29AX, P29CB, P29NPM, and XYLs P29SM, P29DI, and P29RM. It is the aim of the Institute to translate the Bible into native languages; translations into 24 languages have been completed so far. There are 150 language groups in the field—that is, family groups living with the people in villages and studying their languages. A gigantic undertaking in a country of 700 different languages amongst a population of 3 million!

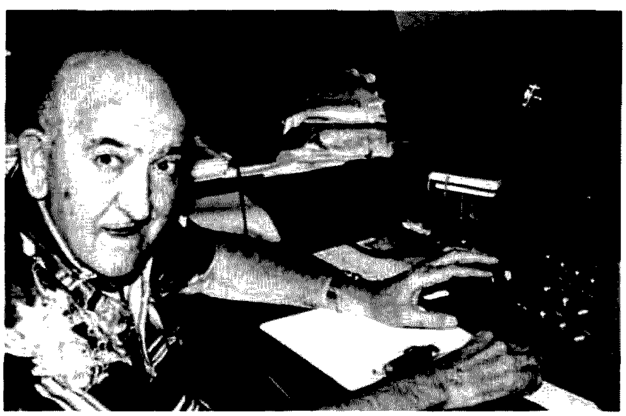


GUAM

James T. Pogue KH2AR
68 Banyan Circle
FPO San Francisco 96630

THE VIEW FROM GUAM

If you have sent or received a QSL card through the Guam Bureau during the last 10 years, then you can thank Joe Frekot



Guam's Joe Frekot AH2G.

AH2G. Fondly known on our island as "Oscar the Grouch," Joe traces his ham-radio roots back many years.

Using a UX201A as the heart for his first receiver as well as his first transmitter, Joe was first licensed and went on the air in 1931. Signing W3CHH from Philadelphia, Joe managed on more than one occasion to work California with just over 3 Watts.

Prior to WWII, he worked for the Ballistics Lab at the Frankford Arsenal in Philadelphia. In 1944, he went to work for Western Electric as a field engineer. When WWII ended, Joe signed on with Philco as a tech rep and started traveling. His new duties made the entire Pacific his backyard and took him to Guam, Iwo Jima, Eniwetok, the Philippines, Okinawa, Japan, Hawaii, Vietnam, and Thailand, to mention just a few destinations. During this time he held the calls KX6BT, KR6FT, and KG6JAR in addition to the two callsigns already mentioned.

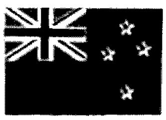
Today, Joe is in many ways like the avid angler who has plenty of fish stories to tell. "I've worked over 300 countries and never used a beam," he says. The only difference between Joe and the fisherman whose catch got away is that Joe has a huge pile of QSL cards to prove his stories.

When asked about what constitutes a rare DX station, Joe says, "A DX station is any station that I haven't worked yet." Judging from the towering stack of filled log books next to his operating table, there can't be too many stations left in that category.

Retired since 1977, Joe is the exclusive dealer for Kenwood gear on Guam, along with several other lines of antennas and accessories. This, along with the QSL Bureau, contesting, and just plain rag chewing keep him occupied most of the time.

Along with his many accomplishments over the years, Joe is listed as an "A-1 Op," a member of the "First Class CW Operator's Club," and is a life member of the IEEE.

When asked about the future of ham radio and whether he thought it was a dying hobby, Joe just smiled and pointed at the brand new "930" on his desk. It looks as though Joe and ham radio will both be around for a long time.



NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

The New Zealand Association of Radio Transmitters (NZART) is the New Zealand equivalent of the ARRL and represents ZL amateurs within New Zealand and internationally.

NZART is controlled by a president and 17 councillors, all elected by the members every two years. The councillors represent the four Districts on a proportionate basis as follows: 1st District, 6; 2nd District, 6; 3rd District, 3; 4th District, 2. The vice-president is appointed from amongst the elected councillors. There is one salaried officer of the NZART, the general secretary, and our headquarters are in Astral House, Upper Hutt, near Wellington. All other NZART departmental managers and officers are honorary positions carried out in conjunction with the members' normal vocational or professional duties.

The business of NZART is conducted during the year between Annual Conferences by the Executive Council, a Secretarial Committee, and the various departmental managers. The NZART Council has at least two meetings during our Annual Conference, which is held the first weekend in June every year. At these meetings, members consider policy and domestic matters before and after the conference and receive reports from the various departmental managers and officers. The Council also meets every month on the air on 80 meters, where members discuss and decide on matters relevant to the day-to-day running of the organization.

The Annual Conference, our association's annual general meeting, is held in different towns and cities, and each of the 80 branches may send a delegate. Individual members may attend the conference and speak and vote on any motion discussed on the business agenda of the conference if they so desire.

The business conducted consists of the Annual Report and Accounts, reports from departmental managers, and remits. Remits (submissions for conference consideration) may come from the Executive Council, any branch, or any five members; subjects covered are association policies, domestic matters, and regulatory matters, and if carried by the vote of conference are (with the exception of regulatory matters) actioned by the Executive Council. Remits on regulatory matters carried by conference vote can only be sent forward to the regulatory body, the New Zealand Post Office, with a suitable recommendation. The New Zealand association is probable unique in that its members control its policies through the annual general meeting.

NZART publishes a monthly magazine, *Break-In*, operates the ZL QSL Bureau, ZL Contests and Awards, a Radio Training Scheme, the Amateur Radio Emergency Corps (AREC), and an Intruder Watch, has a liaison officer to deal directly with our regulatory body, and has three overseas liaison officers who represent New Zealand at IARU and other overseas conferences such as WARC.

BITS 'N' PIECES

IARU Region 3 Monitoring Service Coordinator, Alf Chandler VK3LC, has been forced to retire for personal reasons, after many years of Monitoring Service and Intruder Watches. He has been replaced by Bob Knowles ZL1BAD/ZL6IW, who has been New Zealand Intruder Watch Coordinator for the last four years. He has applied to the IFRB for "direct access" on behalf of the Region 3 Monitoring Service which, if granted, will enable that service to submit reports of "harmful interference" to the Amateur Service without going through the National Administration concerned. In the past, National Administrations, with a few exceptons, have been noticeably reluctant to act as provided for in ITU Radio Regulations. An approach along similar lines has been made also to the New Zealand Administration, and these moves to obtain direct access to the administrations concerned should make it possible to achieve better results in the future.

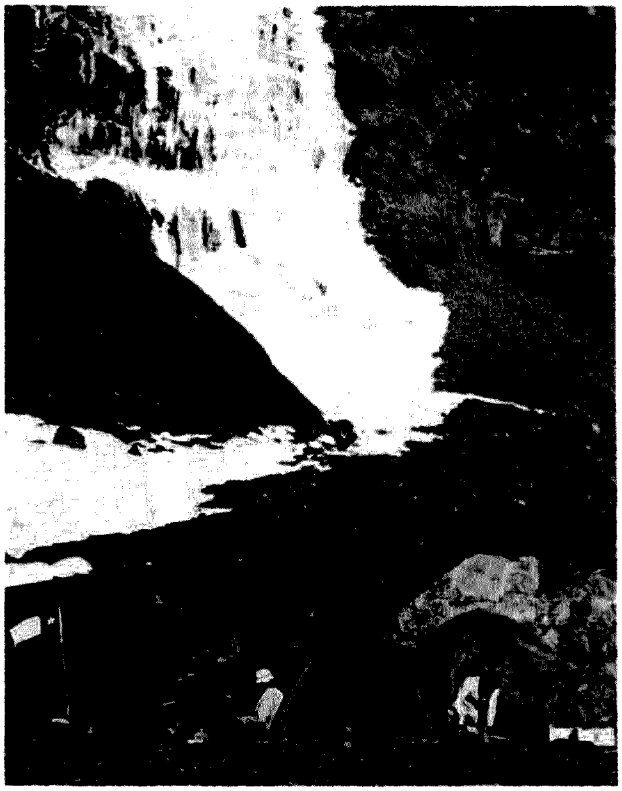
A point of interest regarding Bob's ZL6IW callsign: The New Zealand Post Office recognizes the value of NZART's Intruder Watch, and in what could be a world first, issued the special callsign for Intruder Watch business. It is not permitted for amateur QSOs, but is to be used expressly for transmissions, mainly on CW, to non-amateur stations intruding into the exclusively amateur portions of our various bands.

ZL HAPPENINGS

WCY Activity Day in ZL, 0000 GMT to 2400 GMT, May 21, 1983: special callsigns on all bands, all modes, during the 24-hour period. Remember, commemorative QSL cards for contacts with these special callsigned stations will be sent via the Bureau, but if you want a direct QSL, send an SAE plus 3 IRCs, with details of the QSO, to the ZL WCY station worked, c/o NZART QSL Bureau, PO Box 40-212, Upper Hutt, New Zealand. No QSL cards necessary—only the details of the QSO.

NZART Annual Conference and Convention, Dunedin, June 3-6 in the heart of ZL4-land. Overseas visitors welcome; enquiries to PO Box 6050, Dunedin, New Zealand.

Remember, if you have any queries, don't hesitate to write me at my ZL address; include 2 IRCs for airmail postage for my reply.



Base camp at 9,100 feet with a frozen waterfall in the background.

CHILE

Patricio Fernandez H. CE3GN
PO Box 14781
Santiago de Chile

Chile is an extremely long, narrow, and mountainous country, all of which means, of course, difficult communications.

With the advent of the mass-produced Japanese 2-meter transceivers in the early 70s, Chilean hams began to discover the wonderful possibilities of this band, and it was not too long until the first repeater was installed at the Radio Club de Chile headquarters, on an 80-foot tower, in downtown Santiago.

Experimenters soon discovered that although this repeater had a very nice coverage for normal purposes around the city, the mountains that surround Santiago presented a barrier which made any contact over 20 or 30 miles completely impossible.

In addition to the Andean range, which is a natural borderline between Chile and Argentina, the country has another coastal range which runs parallel to the Andes and is situated very near the coast. These mountains were the cause of the problem in trying to establish 2-meter contacts from the capital to various cities situated along the coastline, such as Valparaiso, Vina del Mar, and San Antonio.

After much investigation and tests from various spots, other repeaters were installed by the Radio Club de Chile during the late 70s. Of these, the most successful have been La Cantillana at 7,500 feet, La Dormida at 4,700 feet, and San Ramon at 3,900 feet. Some firsts have been established via La Cantillana. The most important was the commencement of mobile communications between the continent and Robinson Crusoe Island (Juan Fernandez Arch. CE0Z) some 480 miles from the coast; contacts between Chile and Argentina across the Andes, which are, of course, a formidable natural barrier, were also made.

Back in July, 1982, Radio Club de Chile, which is the largest amateur radio organization in the country, decided to study the possibility of placing a repeater on a very high spot in the Andes. This repeater would have to be high enough to permit reliable communications between Santiago and all the coastline and south of Santiago. This repeater would be the first of a series of linked repeater systems north and south of the capital.

The project was assigned to Ricardo CE3XJ and Saul CE3ZI, who, in addition to being hams, are also experienced elec-

tronics technicians actually working for the Chilean TV net, which covers over 1,500 miles using over 100 repeaters.

As the project involved mountain-climbing knowledge, they contacted Flavio CE3CHH, an experienced climber, and did some research work studying most of the high peaks of the Andes near Santiago.

They finally came to the conclusion that it would be possible to install a solar-powered repeater on top of Cerro El Plomo, which has an altitude of 18,000 feet.

During the next months, both Saul and Ricardo, assisted by other hams, designed, built, and tested a double repeater (15 W on 146.7 less 600, and as a backup repeater, 1.5 W on 146.73) using factory and custom-made parts. An automatic system was included in order to disconnect the batteries if their charge level falls beyond tolerable limits. The same circuit connects them again after 70-percent charge has been regained.

The system was installed on top of Cerro San Cristobal, a hill situated practically at the side of Santiago, and was given a test run of over two months.

In the meantime, CE3CHH had organized the mountain climb to El Plomo with five friends, all members of the Rama de Andinismo of the University of Chile. They had studied the route and had come to the conclusion that the project was feasible, although the biggest problem would be to carry almost 900 pounds of electronic equipment, food, and other gear up to 18,000 feet and then spend at least one day at that altitude in order to assemble everything and make it work.

At that height, even in summer, temperatures can easily reach 20 degrees C below zero, and the oxygen available is about 50 percent less than normal at sea level.

A helicopter would have to transport most of the gear up to at least 13,000 feet, and then mules would have to be used as much as possible above that altitude.

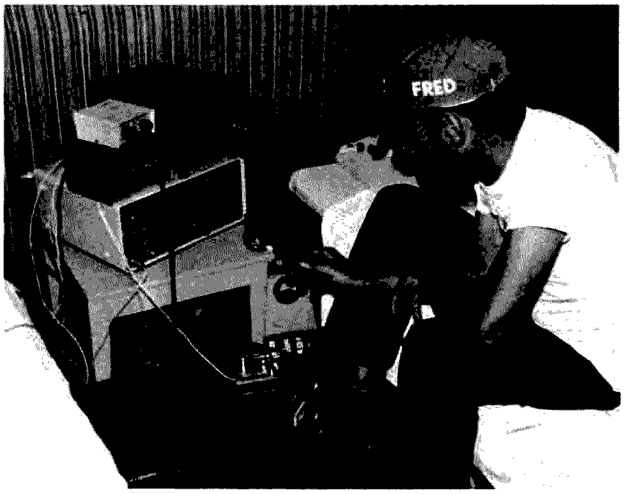
The operation started on January 25. On that date, Flavio and the rest of the team and gear were transported to Farellones by car. Farellones is a skiing resort village about 30 miles from Santiago and has an altitude of about 6,200 feet.

The next morning at 6:30 am, the helicopter from Santiago arrived, piloted by Maj. Pulgar, a most experienced flyer from the Chilean Highway Patrol Police. Two climbers boarded the BO-105 with the mission of getting as far up as possible on the slopes of El Plomo.

Unfortunately, flying at those altitudes is extremely difficult and dangerous, as downdrafts are common—and that day was no exception. Several attempts were made to reach a flat spot at about 13,000 feet, and on the last attempt, the craft was caught by a vicious downdraft which carried them down for about 2,000 feet, almost scraping the rocks on the mountain slope.

After that experience, it was decided to carry the gear to another spot located at about 9,100 feet at the base of El Plomo. Seven flights were made from Farellones to that spot, carrying all the gear and men. On a final successful attempt, the helicopter loaded the batteries, each of which weighed 80 pounds, and landed safely at 10,500 feet. From then on, the climbers had to hand-carry most of the gear up to 15,700 feet in successive trips; this took 3 days.

On the fourth day, they had to bear a heavy storm with hail and snow which kept them under their tents for over a day. On January 29, the mules that had been requested some days before finally arrived, so the batteries and other heavy gear were loaded on the animals. After two days of very difficult climbing, they reached 17,000 feet with all of their gear.



Fred PYØZZ operates from Fernando de Noronha.

At this height, the mules were so exhausted and the terrain so rugged that it became impossible to use them any more, and they had to be left aside. The route from this point to the top of the mountain goes through a very steep glacier over one mile in width, very difficult and dangerous to cross.

It took the climbers another three days to reach the top with all of the gear on their backs. At this altitude, and without the mules, the task was almost unbearable. Finally, on February 2, after ten days of climbing, they reached the top and the repeater and two antennas were assembled, placed into position, and the first contacts were made that afternoon with Santiago.

The group then returned to the night camp at 17,000 feet and Flavio waited until the next day to climb to the top again and further check all the system. At 10:30 they started their way down, arriving at Farellones that night, where they were greeted by various hams from Radio Club de Chile.

The system has been working very nicely since, and there is reason to believe that it will survive many winters. The coverage is enormous, and the sensitivity is such that hams situated on the coast can work through the repeater using only hand-held gear. After all, it's the world's highest repeater.

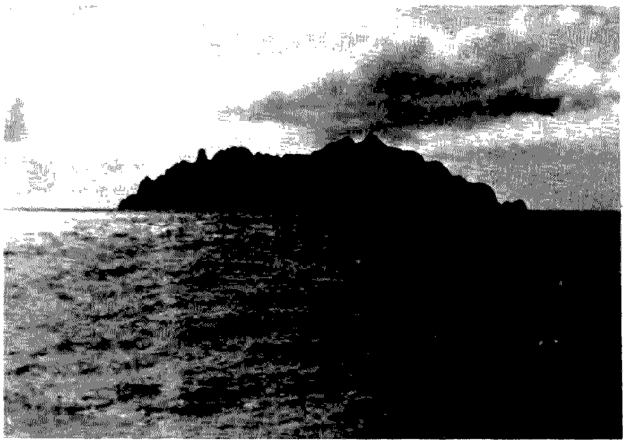
FERNANDO DE NORONHA ISLAND EXPEDITION

Last October, PYØZZ and PYØCW were again on the air from Fernando de Noronha Island. Fred PYØZZ operated from October 9 to 10 and Andre PYØCW operated from October 9 to 26. They operated on all bands in spite of the heavy noise, especially on 80 meters, produced by the generator located in front of the hotel. Fred made about 8,000 QSOs and Andre 3,000. Andre took advantage of the trip to work on the island, so he did not have too much time to operate.

They used a Yaesu FT-201, which burned out the fourth day of operation, and a Delta 500, a Brazilian transceiver. After this accident, they could not be on the air at the same time. The antennas were a dipole for 40 and 15 meters and a Hy-Gain 18 AVT.



Trindade Island.

Fernando de Noronha Archipelago lies in the South Atlantic, 300 miles northeast of Natal. Its geographic coordinates are 30°50'27"S, and 32°24'52"W. It is composed of twenty islands among which Fernando de Noronha, Rata, and Rasa are the main ones. Its area is only 10,422 square miles. Its average temperature is 77° F.

Fernando de Noronha is called The Emerald of the Atlantic by Brazilian and foreign tourists. It has a population of about 1,500 and is the smallest unit and the only military territory in the Federation of Brazil. It is under the direct control of the Ministry of Army. There are Army troops as well as Air Force people working there. Civilians living on these islands have several activities—fishing being the main one.

AWARDS

ABCW Award: Sponsored by the ABC Group of CW, the ABCW Award is available to all licensed amateurs for confirmed contacts with 5 (five) different ABCW members. Contacts must have been made after March 29, 1980, on any amateur band. Only two-way CW mode. No QSLs. Send GCR log of stations worked (call, date, time, band, mode, and report), your personal QSL, and 10 IRCs for mailing expenses to: ABCW, PO Box 285, 09700 Sao Bernardo do Campo, SP, Brazil.

Endorsements: For confirmed contacts with 10, 20, 30, and 40 PY2 stations.

SWL: Same rules.

ABCW Members: PY2AAW, PY2AFG, PY2AMU, PY2ASI, PY2CQM, PY2DEH, PY2DMY, PY2EJX, PY2FKD, PY2FWZ, PY2FXK, PY2FXR, PY2HAB, PY2IAP, PY2IAT, PY2IBE, PY2ITA, PY2JM, PY2RAN, PY2SHC, PY2SHI, PY2THM, PY2TNG, PY2USC, PY2VHW, PY2VIW, PY2VTJ, PY2XA, PY2XR, PY2YDD, PY1AEE, PY1AJK, PY4AUB, PY4BNL, and PY4SS.

TRINDADE ISLAND

One of the Brazilian ocean islands with DXCC status, and 620 miles from Victoria City on the coast of Brazil's Espirito Santo state, Trindade is a savage volcanic island rising from 5,500 meters depth to form a surface of 8.2 square kilometers.

Abruptly steep and covered by low grass and herbs, with trees five and six meters high and giant samambaias, Trindade Island seems to be a lost paleozoic forest in the middle of the Atlantic Ocean.

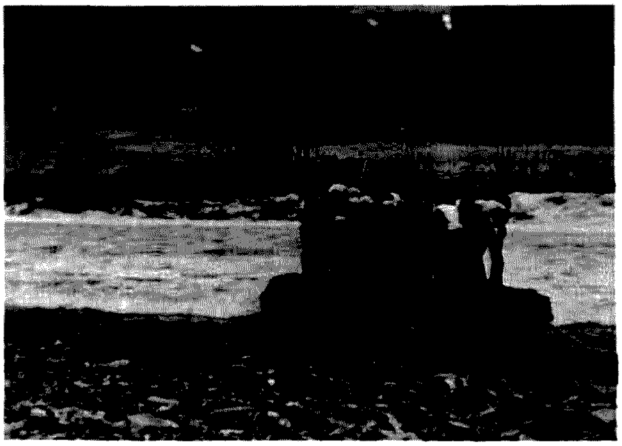
Giant sea tortoises look for Trindade as an ideal place to lay their eggs, and year after year they come by the hundreds. Wild goats and pigs brought to the island many years ago are inhabitants. Crabs by the thousands live there, and so do sea birds—the newborn tortoise's worst enemy in nature's struggle for life.

A five-minute daily rain was named Pirajá (Peer-ar-jar) by Marines who have a 4-month stay at Trindade, joining a Navy detachment for weather-prediction programs.

Fishing is the main hobby, and it sure is fun there—a paradise of the finest fishes you can imagine, lobsters and barracudas, and also little black fish who are such fools that you can catch them barehanded. "Fish me, please," is what the men call them.

Fresh drinking water comes from the tops of the sloped volcanic hills of this impressive 600-meter-high mountain, with its lava flows and volcanic sand all around. The mountain was discovered in 1501 by a Spanish captain who was serving the Portugese king at the time.

Every two months, a Navy supply boat lands for a few days, bringing 50 percent of the island's crew and returning home with another 50 percent who have fulfilled their 4-month tour of duty. This is the chance for radio amateurs to get ashore



After a four-month stay on Trindade, it's back to the continent.

and put Trindade on the air: a sure pileup as long as the stay lasts! Landing at Trindade is not easy; stone walls surround the island and there are very few places where a small boat can get in.

If radio amateurs are lucky enough to have a helicopter aboard, that is wonderful, and this is how they will be taken ashore. But if not, a boat is sent close to the island and a rope is shot out so that they can pull the cable through a pulley and back to the ship. Then a raft about three by three meters, made from boards tied to empty oil drums, is shuttled between the island and the ship until everything is landed—men, goods, and equipment.

It's all very easy until you get near strong breakers close to shore, with waves sometimes covering men and supplies alike, including all amateur gear, thus causing much distress. Although gear may be perfectly wrapped in plastic, there will always be water dripping from transceivers.

Even so, Trindade Island is a marvelous challenge to Brazilian amateurs, and the tremendous fun of an operation from the much-awaited PY0T is a permanent push to an adventure never to be forgotten. This means that if you ever hear someone calling "CQ...CQ...de PY0T...Trindade Island," you can bet he's in paradise.

Radio amateurs can count on Navy sympathy when possible. Of course, there is no Waldorf Astoria Hotel at the island, but the people there are extremely friendly and do their best to help amateurs. And this is why friends who have been operating from there are always dreaming about "the next time I go to Trindade Island." I have never been there, but I dream of it myself...

D 6000 Frankfurt 50
Federal Republic of Germany

The Deutschland-Diplom (DLD Award) sponsored by the German Amateur Radio Association (DARC) is not too difficult to get and it is issued in the form of a beautifully-designed certificate in full color. But effective January 1, 1983, new regulations apply. Here are the essentials.

Two classes of DLDs are available—DLD 100 and DLD 200. For European applicants, 80m contacts only are valid while all other amateurs may use 80, 20, 15, and 10 meters. Two-way communications are required in any legal mode of operation. Each confirmed DOK number (see below for explanation) is counted as 1 point except for non-Europeans who may count 2 points for each DOK number confirmed on 80m. 100 or 200 points respectively are needed to get the DLD 100 or 200. Contacts on or after January 1, 1956, are valid.

For 40m contacts, the DLD 100/40m and DLD 200/40m are available. Uniform regulations exist for European and all other applicants, i.e., 1 confirmed DOK number is counted as 1 point. Contacts on or after May 7, 1959, are valid.

Lapel pins are offered in the following categories: Bronze for DLD 300, i.e., DLD 100 + DLD 200/40m, or DLD 200 + DLD 100/40m, or DLD 200 + 100 additional DOKs on 80m, or DLD 200/40m + 100 additional DOKs on 40m. Silver for DLD 400, i.e., DLD 200 + DLD 200/40m, or DLD 200 + DLD 100/40m + 100 additional DOKs on 80m, or DLD 200/40m + DLD 100 + 100 additional DOKs on 40m. Gold for DLD 500, i.e., DLD 200 + DLD 200/40m + 100 additional DOKs on 80m, or DLD 200 + DLD 200/40m + 100 additional DOKs on 40m. Non-Europeans may use 80, 20, 15, and 10 meters to fulfill the 80m requirements. And in addition to the lapel pin in gold, stickers are available in green, red, silver, and gold for 600, 700, 800, and 900 confirmed DOKs. Top of the line is the DLD 1000 award which requires a total sum of 1000 confirmed DOKs. The DOKs confirmed on 40m are counted separately if one applies for stickers or for the DLD 1000 award.

1982 GARTG* SSTV CONTEST SUMMARY RESULTS

	Call	1st part	2nd part	Total points
Group A (Shortwave transmitting stations):				
1.	JA1XGI	12750	37600	50350
2.	LZ1MH	8008	24552	32560
3.	EA3PE	7547	15336	22883
4.	LZ2OV	1155	12320	13475
5.	I3BQC	3145	6804	9949
6.	I4LRH	900	2428	3326
7.	DF7XA	-	1672	1872
8.	HA1ZH	800	-	600
9.	F5WF	-	312	312

2.	DG6DAF	-	418	418
3.	NL 4483	-	192	192

*German Amateur Radio Teleprinter Group.

DOK Designations

The Distrikts- und Ortsverbands-Kenner (DOK) is composed of a letter and a numeral representing a particular district and the local group of DARC in that area. For example, the DOK H03 represents the district of Niedersachsen and one of the local groups in Braunschweig/Germany. Several groups may exist in larger cities. (See the table.)

The letter Z is employed by radio amateurs who are affiliated with the German Department of Telecommunications. Their organization, Verband der Funkamateure der Deutschen Bundespost e.V. (VFDB), is a corporative member of DARC. And there are special DOK numbers from time to time as, for example, WCY for 1983, IBO33 from 1st April to 31st July, 1983, and IR33 from 1st August to 30th November, this year.

Confusing? If so, get your feet wet by starting with the DLD level having the simplest rules: the DLD 10m. Only 50 DOK numbers confirmed on 10m are required—that's all. Contacts on or after January 1, 1976, are valid.

The fees are moderate, on the order of 10-15 DM($4.00-$6.00 approx.). Complete information and application forms may be obtained from the DLD manager, Mr. H. P. Guenther DL9XW, Am Strampel 22, 4460 Nordhorn 1, Federal Republic of Germany.

AMATEUR RADIO SATELLITE

AMSAT/DL has been notified by ESA (European Space Agency) that the launching date for the AMSAT Phase IIIB Amateur Radio Satellite, DL0WCY, is expected for May 27, 1983. This means the satellite will be shipped to Kourou (French Guiana) in mid-April, followed closely by the launch control crew. If no unexpected delays in the pre-launch procedures happen, the satellite should be in orbit about 3 years after the disastrous false start from the ARIANE L 03 flight in 1980.

Negotiations concerning the launching of a Phase IIIC satellite from Vandenberg, California, are presently unsuccessful.

QSL MANAGERS

A listing which contains over 2000 QSL manager addresses can be obtained for 15 DM or equivalent from Arthur Maurer DL8BL, Beim Weisenstein 9, D-6602 Dudweiler, West Germany.

CONTEST CALENDAR 1983

Date	UTC	Name	Bands	Mode

ITALY

Mario Ambrosi I2MQP
Via Stradella, 13
20219 Milano
Italy

The scene has been dominated by the VK0 expeditions. Even if difficult to understand, the reason for two expeditions to this same spot in the same period of time has been the thrill to be on frequency there. Signals from VK0HI were very strong the first days of operations, but then the propagation dropped. When VK0JS appeared, the demand for Heard was still tremendous. The pileups on 14195 were incredible, and sometimes VK0HI was on 15 in the same period, working his own frequency with no customers.

Italian operators have been very lucky because, with such propagation, many North Europeans were not able to copy Heard. Most of the contacts have been made on 20, a few on 15, and very few on 10. 40 and 80 have been dominated by CW with few contacts on SSB.

RADIO IN ITALY

The national body for amateur radio in Italy is the Associazione Radioamatori Italiani, or ARI. It has an elected council of 8 members in charge for a term of 3 years.

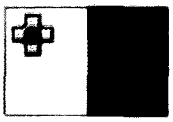
The first honorary president was Guglielmo Marconi. Today, the council consists of a president, a vice-president, a secretary, and five other members. Others who play important roles are the various managers, one for each kind of activity: DX, VHF, Awards, RTTY, QRP, ATV, SSTV, SWL, Repeaters, Reciprocity, etc. I will report on the above topics in the future.

The official monthly magazine, *Radio-Rivista* (it means Radiomagazine), also known as *RR*, is somewhat in between *CQ*, *73*, and *QST*. Like *QST*, *RR* gives ample reporting on League activities like meetings, division activities, hamlests, and others. As *73* and *CQ*, it widely covers DX, awards, new rigs, and antennas.

The magazine has changed substantially during the last months with the new management of two professional journalists: Nax Di Marco I2DMK and Angelo Pinasi I2PKF, who is also the DX editor. The new format of *RadioRivista* resembles *Time* and consists of about 120 pages, of which 40 are devoted to advertising. Advertising is more or less the same in Italy as in the States, but there are no toll-free lines and prices are never mentioned in the newspaper. Dealers do not like to compete too much against each other (the market is relatively small); they do prefer to squeeze the customers.

The total number of hams in Italy is around 24,000, and 50% of them are members of ARI. The cost of membership is 38,000 lire (about $27.00), which includes the handling of incoming and outgoing QSLs without other costs and without any limit in quantity (I personally send 6,000-7,000 cards per year). To top it off, an antenna insurance policy and some other small additional benefits are included in the fee.

In our country, we are very proud of the fact that the first radio amateur (as he liked to call himself), G. Marconi, was Italian. If it happens that you work IY4FGM, you will be interested to know that this club station is transmitting from the same room Marconi used to make his experiments! And to your surprise, if you visit the Manhattan World Trade Center, on one of the observation decks of "The World at Your Feet," you will find: "The radio—an American invention"!



MALTA

C. A. Fanech 9H1AQ
35 Main Street
Attard
Malte

THE MALTESE ISLANDS

The Maltese Islands, consisting of Malta, Gozo, Comino, and two other small, uninhabited islands, are situated in the middle of the Mediterranean Sea about 93 km south of Sicily and 288 km from North Africa. The total area is 315.6 square kilometers, with Malta having approximately 248 of them. The longest distance in Malta southeast to northwest is about 272 kms, and the widest east/west distance is about 14.4 km. The population of Malta is 320,000. Valletta is the capital city of Malta. The main seaport is the Grand Harbour at Valletta, which is surrounded with magnificent bastions recalling great historical moments in the history of the Maltese Islands. The only airport is situated at Luqa, about 6.25 km from the capital city.

Malta boasts of a very temperate climate. There is no snow, fog, or frost. Rain falls only during short periods, usually between October and April, averaging about 55.9 cm in a whole year.

On such a small island as Malta, there are about 150 licensed amateurs, of which only about 90 are active. The two types of licenses issued consist of License A and *License B. Holders of the A license must* pass an examination in radio theory and operating procedure and a Morse test of 12 words per minute. Holders of such a license are allowed to operate on all bands with 150 W dc input (10 W on 1.8 MHz). License B holders also have to pass the theoretical examination but do not need to sit for a Morse test. Holders of such a license are allowed to operate only on VHF, i.e., from 144 MHz upwards. The following are the callsigns issued in the Maltese Islands: 9H1 followed by one or more letters denotes a category A license holder. 9H5 followed by one or more letters denotes a category B license holder. 9H4 followed by one or more letters denotes a category A license holder living in Gozo. 9H3 followed by one or more letters denotes a category A license issued to a visitor who comes to Malta for a short period. (There are no licensed radio amateurs on the Island of Comino.)

A license to set up an amateur radio station in Malta costs three Malta pounds (about $1.20), renewable every year. Such a license is not transferable.

The Malta Amateur Radio League (MARL) is the society that represents the majority of radio amateurs in Malta. It has IARU recognition and is affiliated with the ARRL and the RSGB. The club is situated at The Parochial Centre, Attard, and the official address is Malta Amateur Radio League, PO Box 575, Valletta, Malta. Meetings for members are held every Tuesday and Thursday evenings and every Sunday morning. Courses, free of charge, are also given for those members who would like to obtain a license. The society also runs a very efficient QSL Bureau.

How To Apply

Following are the requirements to apply for permission to establish and use an amateur (sound) station; applications should be made to: The Chief Inspector of Wireless Telegraphy, Castille, Valletta, Malta, Europe, and should include:

A.1. Name of applicant (with full Christian names)
A.2. Date and place of birth
A.3. Home address
A.4. Details of occupation
A.5. Telephone number
A.6. Citizenship and passport number
A.7. Father's name
A.8. Mother's name and maiden surname
A.9. Address of where the amateur station is to be set up
A.10. Duration of stay in Malta (from . . . to . . .)
A.11. Qualifications (amateur license); copy of current license is to accompany the application
B.1. Transmitter(s). Type, class(es) of emission, power, frequency coverage, etc. Circuit diagram to be enclosed with the application. (Maximum dc power energizing the final stages or any device energizing the aerial shall not exceed 150 Watts. Hand portable equipment is not allowed. Mobile operation is likewise not permitted.)
C.1. Receivers. Types, modes of operation, frequency coverage, etc.
D.1. Details of any other equipment
E.1. A declaration by applicant that (s)he will adhere to all the conditions of the radio amateurs in Malta

Applications for such a license should be made at least 3 months in advance of arrival on the island.

SCANDINAVIAN HORIZON

The amateur radio world is divided into three regions. Europe, Africa, and parts of Asia belong to Region 1, North and South America belong to Region 2, and Southeast Asia, Australia, and the South Pacific belong to Region 3. Region 2 has the most favorable frequency allocations compared to the two others. In Region 1, the amateur bands 50 MHz and 220 MHz are assigned to other services. The 160-meter band was, with a few exceptions, not assigned to hams until 1982, and we are still restricted to just a few kHz and limited power up to maximum 10 W input. Both the 80- and 40-meter ham bands are 200 kHz wider in Region 2 (America) than in Region 1 (Europe/Africa).

LICENSING IN SWEDEN

The Swedish Amateur Regulations were revised during 1982. Generally speaking, these put tighter restrictions on the hams, which is unfortunate. For example, Swedish hams initially were forbidden to participate in satellite communications on the 432-MHz band. We still are strictly forbidden to operate on the 21-MHz band if we may interfere with radio and TV broadcasts when the affected receiver has an i-f with this frequency or a harmonic thereof. Furthermore, we were told that having a transmitter capable of transmitting outside the ham bands was illegal after October 1, 1982. This made all commercially-marketed ham rigs illegal at once! Practically all equipment has some overlapping, and a rule like this will only degrade the respect for regulations.

SSA, the Swedish amateur radio league, is trying to negotiate with the authorities, and the restriction on 432 MHz for satellite communications has been lifted.

Since the early 70s, Sweden has had four classes of ham licenses. The fourth class we got ten years ago was a Technical class for VHF with no Morse code requirement.

Looking at the license class structure in Sweden (see the table) makes one wonder why there are four classes when the difference is so small. In fact, most countries have only two classes, a Novice class and a General class. Basically, the requirements for achieving a license in various countries is much the same. The most common code speed for the highest license class is 12 wpm (60 characters a minute). Sweden with 16 wpm and the US with 20 wpm are two exceptions. The written exam covers about the same but is of course structured according to the different classes in each case.

LOW INCENTIVES

There used to be a gain in privileges by upgrading in Sweden. During the last decades, the difference has become less obvious and there is not much of an incentive any more, especially since the recent change increasing the power levels for class B licensees from 75 W to 250 W and class C from 10 W to 100 W without giving the class A anything new. The concern for TVI/RFI has been the major reason for keeping the old 500 Watts input as maximum.

In the late 50s, when I got started, I had to wait till I turned 16 before I could try for my Novice ticket. This gave me 15 kHz on the 40m band CW (7035-7050 kHz) with 5 W input crystal-controlled. Much the same as your Novice ticket, but we sure envied your 75 Watts. Ours was not renewable either, and we had to upgrade before turning 19 or find something else to do. (This limit has also been changed.) The code speed was and is still 8 wpm for class C.

NOVICES IN FINLAND

I never forget those days when the Novices in Finland always did beat me with their marvelous 15 Watts. When an OH ham popped up on my crystal frequency, he usually stayed there for about two weeks. That was the time it took him to work the 250 QSOs required before he could upgrade. It did not take many days until there was a new one with the same crystal on "my" frequency for another two weeks. I had to work one year before I could upgrade and "go vfo."

OTHER NORDIC COUNTRIES

Finland and Norway have two classes of license, a Novice and a General, while Denmark has four classes structured the same way as the Swedish system. Their age limits differ, though, starting with 13-year-old Novices. Finland does not have age limits as the other countries. Hams in OH-land can use up to 600 W output which can be compared with 600 W input for the Norwegians. The Norwegians are even prohibited from owning a transmitter capable of more than that limited dc power. Denmark and Sweden have an upper limit of 500 W dc input. Another peculiarity I have found is that in Norway you have to identify with your callsign every 5 minutes. Most countries have followed the 10-minute recommendation made by the ITU.

WARC BANDS

Denmark has opened all the three new bands for their hams. This, of course, also includes OY, the Faroe Islands. Norway was also *heard on 10 MHz* right away on

Class of License	Minimum Age	Modes of Operation	Max. Power Input	Amateur Bands
A	17	All	500 W	All
B	16	CW, RTTY On 28 MHz and above, also phone	250 W	All
C	14	CW, RTTY On 28 MHz and above, also phone	100 W	All but 20 meters
T	17	All	75 W	144 MHz and above

License class structure in Sweden.

January 1, 1982, when that band could be opened for the first time. Finland has had operating privileges on 160 meters for years. It is still unknown when we in Sweden may get any of the new WARC bands, and the 15 kHz we got on April 1, 1982, on 160m are only opened on a trial basis and "can be revoked immediately if other services are interfered with or if there are put forward any objections internationally of fundamental nature against these transmissions." Our power limit for this band is 10 W input, only CW (class A1A).

CODE-FREE LICENSE

A possible code-free license in the US has been discussed a lot lately. We got such a license ten years ago—the so-called T license (T for Technical). The idea was to give CBers a chance to get into ham radio without having to put in that extra effort required to learn the code to start with. It was obvious that lots of people got into CB because of some interest in radio communication as a hobby and not to use CB as it originally was intended to be used.The hope was that these people would get a deeper interest in amateur radio and upgrade, and the national amateur league accepted this new license.

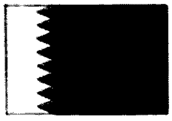
Many became genuinely interested and eventually upgraded, but a majority of these people stay on 2-meter FM and this is and continues to be their only experience in the wide field of ham radio. The most unfortunate thing, in my personal opinion , is that many of these T licensees degrade themselves by indicating a feeling of inferiority because of not mastering the code. This, however, is apparently not enough to make them go through the effort required by everyone for learning this skill. In some cases, this fact has produced an unnecessary strain between groups of hams which is difficult to avoid.

A summary of our ten years' experience with a code-free VHF license is that the Swedish ham population has grown considerably. There are now almost half as many T licensees as class-A licensees. About 90 percent of all new licenses issued are class T. Some of them are indeed technical people, but most of them stay strictly on 2-meter FM.

You have probably heard 3 or 4 different Swedish prefixes on the air. Most common is SM, which is granted to all persons passing the exams. SK is a club station either in a ham club or from a school. These stations are run on a voluntary basis, and two amateurs having the highest level of certificate are responsible for all traffic from such a station. You will find a lot of SK stations on the air when the major contests are on. SL is the prefix of stations belonging to the Swedish defense forces. These are manned by trainees or amateurs doing their national service.

The fourth and most rare prefix is SJ, which is held by one station, SJ9WL, situated in Morokulien—an imaginary country on the border of Sweden and Norway. This "country" was founded during a radio show in the middle of the 1950s. There is a nice hut at the disposal of any visitor, and a licensed amateur can have a choice between using SJ9WL or LG5LG. The station is equipped with gear covering all HF bands as well as 144 and 432 MHz.

Sweden is divided into 8 districts and a ham must change the number in his prefix if he moves from one district to another. The suffix is the same and nowadays lost calls are not given to a new amateur for a long time.



BAHRAIN

Ian Cable A92BW
PO Box 22381
Muharraq
Bahrain

The third biannual Middle East Communications Exhibition (MECOM) took place in Bahrain, February 7-10, and as usual, ARAB (Amateur Radio Association Bahrain) was there. We operated special-event station A99A on the HF bands during the hours that the exhibition was open, with somewhat disappointing results in terms of QSOs made. Unfortunately, the move from the original temporary exhibition site to the new permanent one at the Central Market was not without its problems. In the radio receiving sense, the new location is extremely noisy, with an S7 noise level commonplace on the HF bands; we assume the power line radiated. It didn't help that the tower exhibitor, whose products we had hoped to use to hold up the A99A antenna, was located so far away from our stand that we would have needed a second mortgage to fund the purchase of feeder cable! The best that we were able to manage under the circumstances was a trapped multiband vertical on the roof of the building with an swr on the feedline low enough not to cause any problems. Our apologies to those who called loud and long and didn't make it through the noise.

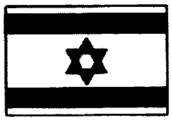
Amateur radio visitors to the ARAB stand at MECOM included stations licensed by the administrations of A71, DL, EA, G, HZ, K/W, OD5, OZ, SV, VE, 5B4, and 9K2. We even had to drag some of the exhibitors, who were also amateurs, away from their own stands in order to sign in at ours.

Also present whilst MECOM was in progress were Lloyd and Iris Colvin W6KG/W6OL, fresh from their exploits in A71. We were more than somewhat startled when they emerged from the Airport Customs Hall complete with transceiver and amplifier on their own suitcase wheels! Regrettably, that was when good luck deserted them; no license was forthcoming. Our Association president, the Minister of Information, was willing to license, but the Security and Intelligence Service of the Ministry of the Interior said no.

Our 2-meter repeater, A92RP, 145.150 MHz in, 145.750 MHz out, 1750-Hz tone-burst access, has recently undergone a retrofit involving the installation of a higher gain antenna. All of the previously marginal scratchy signals are now fully quieting. Maritime mobiles in the Gulf are welcome to make use of the repeater; there normally is activity at around 1830 local time. Future plans are to move the repeater from its present site atop the National Bank of Bahrain to the Gulf Hotel, which will effectively remove it from the downtown repeater rat race. There is absolutely no truth in the rumor that we leaned on Ted A92CE in order to persuade him to move from the Ramada Inn to the Gulf Hotel—but every little bit of influence helps!

Our 28.245 IBP beacon, A92C, has been running recently on the tribander at the clubhouse except, of course, when the club station is in action. The replacement meter switch for the club's FT-101E has recently become available, so we will be able to tune up on the meter rather than by maximum smoke. Next project looks like a 2-meter beacon—we have available a Communicator IV which should be capable of generating the requisite amount of rf and the old repeater antenna to radiate it.

As the springtime propagation picks up, perhaps both A92BE and A92BW can be persuaded to devote time to 20 meters rather than to their respective computers. Let's wait and see what happens!



ISRAEL

Ron Gang 4Z4MK
Kibbutz Urim
Negev Mobile Post Office
85530
Israel

Greetings from Israel to all readers of *73*. This is to keep you informed on what's happening in amateur radio in Israel. I'll be delighted to answer any questions you have pertaining to the ham scene here, so don't hesitate to drop me a line.

If you're active on the HF bands, then it's likely that you've already heard and possibly worked some of us. We number just a touch over a thousand licensed stations at this time, with the prefixes 4X4, 4Z4, and 4X6, this being the order in which these callsigns were issued. The suffixes are two letters with the exception of Novices who have a three-letter suffix beginning with N, the N being dropped upon receiving a higher grade of license.

The Novice, or Grade C license, is the easiest to get. You need six words a minute in Morse, an elementary knowledge of electrical laws similar to that needed for the US exam, and a basic grasp of Q signals, operating procedure, and radio regulations. With this license, which, by the way, is renewable, you're permitted the use of crystal-controlled CW transmitters of ten Watts input from 7.065 to 7.085 MHz and 21.100 to 21.150 MHz.

The Grade B license is comparable in scope to the General class in the States as far as theory is concerned. Here the Morse code requirement is 12 words per minute, and the licensee can then use up to 200 Watts input on all modes and bands with the exception of 160 meters and the three new WARC bands, where power input and frequency range are somewhat limited.

After holding the Grade B license for at least a year, one may then go on to take the Grade A test. You have to copy code at sixteen words a minute, and the theory exam is oral. Although this test is supposedly on a higher level than that of the B exam, many report it to be easier since it isn't written and there is a rapport with the examiner. Besides being able to run a kilowatt input on all but the 160-meter and WARC bands, the holder of this license may receive authorization to connect a phone patch to his station or let others use his equipment under his own direct control.

Examinations take place twice yearly—in the spring and in the fall. There is a higher failure rate here than in the US, but this is probably due to the form in which these examinations are given. The code must be written down solidly in Latin letters—a difficult task for native Hebrew speakers used to a different script. The exam questions are different each time and require a written answer—no multiple choice, and Dick Bash or his Israeli equivalent has yet to appear here.

However, if you already hold a foreign license similar in requirements to either the Grade A or B tickets, you will be exempted from the above ordeal. And the reciprocal licensing here is quite liberal.

How does a visitor to Israel go about getting on the air? He simply appears at the office of the Ministry of Communications on the tenth floor of The Shalom Tower on Ahad Ha'am Street, downtown Tel Aviv's highest building. (It really isn't all that high, but it's all we've got!) He presents his valid license, not a photocopy, and will be granted on the spot, free of charge, a reciprocal license. I've heard American, Canadian, South American, European, and South African callsigns on our repeaters, so it's a fairly easy procedure. Office hours of the Ministry are 9:00 am to 1:00 pm, Sundays through Thursdays, and the phone number is (03)-610278.

Interested in working Israel? Your best bet is on 10, 15, or 20 meters, depending on propagation. These bands are where the local hams are most active, especially on SSB, but there are fellows on the other bands and modes as well. Ricki 4X4NJ is a 160-meter enthusiast, and this winter has improved his antenna farm and has made quite a few QSOs with stateside stations both on SSB and CW. David 4X4VL has been cracking out a lot of DX QSOs on 40 meters with his delta loop, and Dov 4X4DX has been cooking up a storm on 80. I get on 10 MHz from time to time myself, and there are many others. Bear in mind that Israel is two hours ahead of Greenwich Mean Time, and that we are on the Eastern Mediterranean, so if you're hearing Greek or Italian stations, there's a good chance a 4X or 4Z station is sandwiched somewhere in between the QRM.

Our national organization is the Israel Amateur Radio Club, presently consisting of some 700 members including SWLs. The club takes care of in- and outgoing QSL bureaus, publications, VHF and UHF repeaters, liaison with the Ministry of Communications, special events and field days, and the transmission of weekly bulletins. In the near future, the IARC hopes to set up beacons both on ten meters and VHF. All the officials and helpers in the club are voluntary, so we do have our ups and downs. After a low period, in the last few years our QSL bureaus have really picked up and we've received many compliments from abroad.

There is certainly a lot more to tell you, such as the awards offered, special events, the VHF and repeater scene, DXing in this part of the world, amateurs of note here, etc., but I'll leave that for another time.

Build the Weather-Grabber

Don't know why there's no sun up in the sky? With this simple converter, you can listen to National Weather Service forecasts on your 2-meter rig and find out.

N1II received an extra $50 for this Home-Brew I Contest Honorable-Mention entry.—Eds.

Paul M. Danzer N1II
2 Dawn Road
Norwalk CT 06851

Does it look like rain? As you drive along, you can find out by switching in a converter and tuning your two-meter FM rig to receive the continuous broadcasts of the National Weather Service. In 1981 there were almost 100 stations scattered throughout the US and additional stations in Canada providing weather information 24 hours a day. The usual transmitter frequencies of these stations are 165.40 and 165.55 MHz. Two FETs serve to convert these frequencies to two frequencies of your choice in the 144-to-148-MHz band.

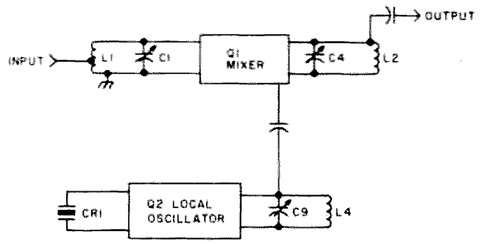


Fig. 1. Block diagram of converter.

How It Works

Referring to the block diagram in Fig. 1, Q1 is a dual-gate FET working as a mixer, with L1 and C1 tuned to the weather frequency. The output of the mixer is selected by L2/C4 and is within the 144-to-148-MHz range of your 2-meter rig. Q2 is also a dual-gate FET, but in a circuit which acts as both an oscillator and a multiplier. Its frequency is set by crystal CR1. If you compare the two weather frequencies with the limits of the two-meter band (162.55 − 148 = 14.55; 162.40 − 144 = 18.40), you can see that for a synthesized rig, any oscillator frequency in the range of 14.55 to 18.40 MHz will allow you to receive both weather frequencies.

The oscillator is both an oscillator and a multiplier. C9 and L4 are tuned to the 14-to-18-MHz range. You can use either a fundamental crystal in this range, a crystal at half this frequency, or a crystal at one-third this frequency.

If you happen to have a crystal in this frequency range, the oscillator operates as a straight-through circuit. Alternately, if you are the owner of an old two-meter or six-meter rig, perhaps you might have some 8-MHz crystals. They will operate fine with the oscillator acting as a doubler. Your third choice is an overtone crystal which is actually one-third this frequency. In any case, try what you have. Just make the subtraction and hopefully the two-meter output will not fall on the same frequency as the local 500-Watt repeater, in which case you might have some feedthrough of hams on top of the weather.

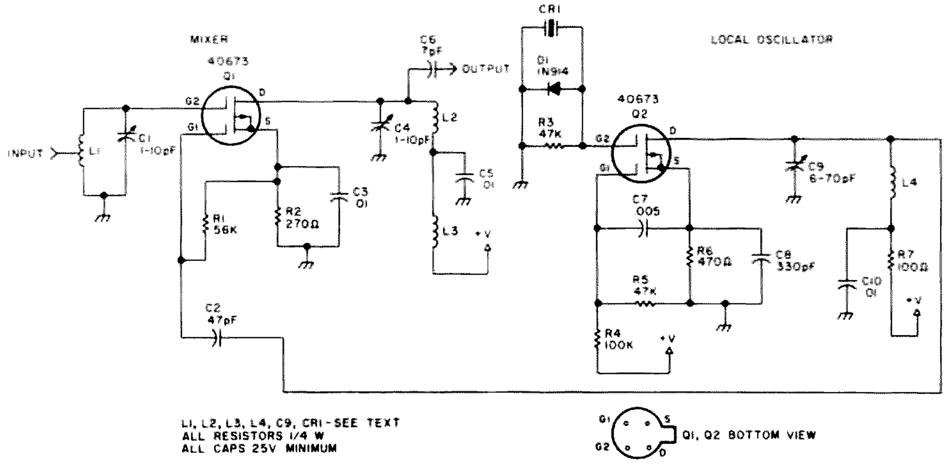

Fig. 2. Converter schematic.

Circuit Design Details

Many hams, including

myself, firmly believe in starting with an existing circuit rather than starting from scratch. If you would like to get into the details of the self-biased mixer used here, you can start with the ARRL *Electronic Data Book*. You might also want to glance at the popular two-meter preamp in the UHF/VHF receiving section of the ARRL *Radio Amateur's Handbook*.

The schematic of the converter is shown in Fig. 2. Both Q1 and Q2 are dual-gate FETs of the 3N211 or 40673 variety. Radio Shack sells them under part number 276-2045. Ideally, miniature trimmer caps C1 and C4 should be variable from 1 to 10 pF, but either the Jameco Electronics TC 2-8 (2 to 8 pF) or the Calectro A1-245 (1 to 7 pF) will do.

L1 is three turns of a tinned number 20 wire wound on a ½-inch rod. After winding, remove the rod. Space the turns so that L1 is about 1 inch long. L2 is also wound on a ½-inch rod and consists of 3 turns without any tap. It is spaced to be about 1¼ inches long. L3 is a commercially wound coil. Any value of 10 uH or more will do (Radio Shack 273-101). If you want to wind your own, take a 100k, 1-Watt resistor and wind 3 or 4 layers of number 30 wire over it. Neatness does not count in this case!

The oscillator is characterized as a "parallel mode Miller oscillator" in an excellent survey of oscillators by VK2ZTB, published in the March, 1976, issue of *Ham Radio Magazine*. C9 and L4 resonate in the range of 14 to 18 MHz. I used a T50-2 core with 12 turns of number 24 wire in parallel with a 6- to 70-pF variable (Jameco TC 6-70). You can use whatever you have as long as it resonates at the proper frequency range. Just be careful that it is not tuned to 7 to 9 MHz or some other related set of frequencies.

Construction

A tracing of the layout used is shown in Fig. 3. Before you make the board, note that the entire board remains covered with copperclad. The lines shown are the *only* areas of bare board. Each of the copper lands is surrounded by a thin line of bare board. Outside of these areas, the remaining board is covered with copper and acts as the ground plane.

The prototype board for this circuit was made by first taking a section of bare printed circuit board and carefully shining it and cleaning it using soap and steel wool. After drying, the entire board was covered with a single layer of masking tape. The edges of the masking tape strips were slightly overlapped and pressed down firmly.

A piece of carbon paper was cut to slightly over the size of the board and placed, carbon side down, on the masking tape. The excess carbon paper is bent over the back of the board and held in place with additional tape. A copy of the layout is now placed on top of the masking tape. With a hard pencil or ball-point pen the layout is copied onto the masking tape by tracing over it on the top sheet.

When you remove the layout paper and the carbon paper, you should end up with a "carbon copy" of the layout on the masking tape. With an X-acto® knife, cut away a thin strip (perhaps 1/16 to 1/32 inch thick) over each of the lines. When finished, you end with the layout in bare copper and the entire rest of the board covered with masking tape.

Now you have two options. Either immerse the board in etching solution and etch until all of the exposed copper disappears, or use a miniature hand grinder and grind away this exposed copper.

The layout and component placement in Fig. 3 is shown from the copper side, but note that all components except the variable caps are placed on the other (bare board) side. Before drilling the holes which connect the bulk of the components from one of the isolated copper pads to the ground plane, check the size. You may want to move the hole in the ground plane in or out to fit the exact component length you are using.

Tuning and Testing

After checking your construction job for solder bridges, missing or incorrect component placement, and cold solder joints, recheck that the FETs are correctly oriented. Remove crystal CR1 and install the converter between your rig and antenna. Apply power and tune your rig to a local repeater. When the repeater is transmitting, you should get some gain through the converter. Tune C4 for maximum signal. You may have to place a 5- or 10-pF cap across C1 to resonate the input to the 144-MHz band from its normal 162-MHz resonance.

Caution: Do not go key down and transmit. There might be a tendency to press the PTT button on your rig to bring up the repeater. If you do, Q1 will probably go up in a tiny puff of smoke and you might damage the finals in your rig.

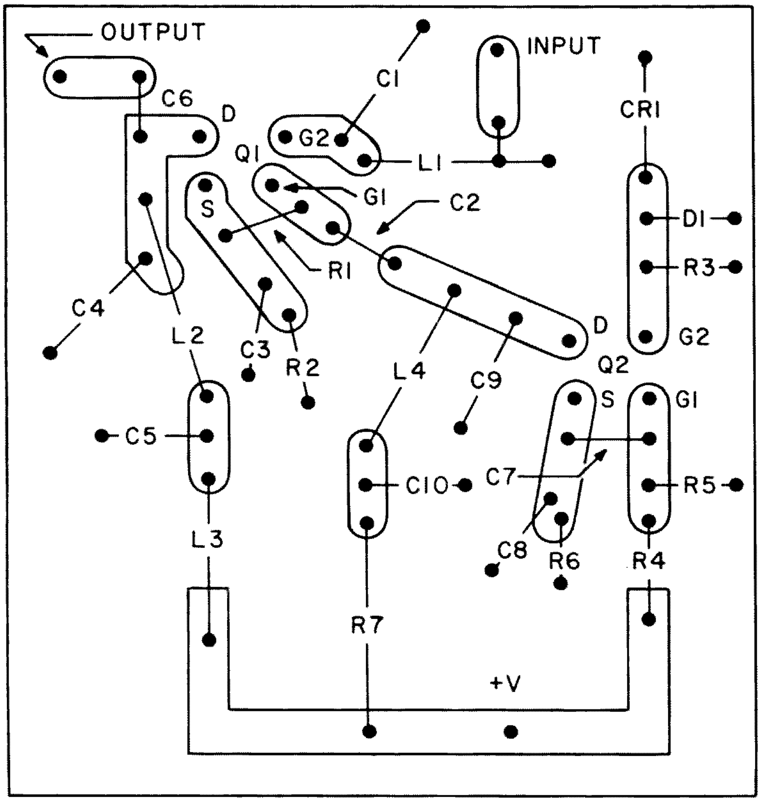
Assuming you get some gain out of the circuit, remove the padder cap across C1 (if you used it) and restore CR1 into the circuit. Check the output of the local oscillator to make sure it is in the 14-to-18-MHz range. You might do this with a high-impedance scope, a counter, or a general-coverage receiver.

If you use a general-coverage receiver, tune it from 6 MHz to 30 MHz and make sure that the strongest output detected is in the 14-18-MHz range. A grid-dip meter can also be used by wrapping one turn of wire around the core and around the coil of the GDO. Again check that the strongest output is in the proper frequency range.

The last step in checkout is to once more make the subtraction: weather frequency − your oscillator frequency = rig frequency. Tune your rig to the proper frequency and there should be the weather station. Gently peak all variable caps and you are in business.

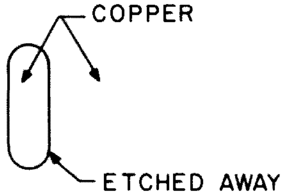
Installation

The weather converter is simply placed between the rig and the antenna. Power of 9 to 12 volts will do; however, if you decide to use the car battery as the power supply, a noise filter



COPPER CLAD SIDE SHOWN. COPPER LANDS SHOWN ARE ETCHED FROM REST OF BOARD, BUT REMAINING SURFACE AREA IS COPPER.

EXAMPLE



ALL COMPONENTS MOUNTED ON OTHER SIDE OF BOARD EXCEPT: C1, C4, C9.

such as in Fig. 4 should be added.

You might also consider installing the converter as shown in Fig. 5. The selector switch (Radio Shack 275-1384) places the converter between the rig and the antenna. In addition, the microphone cable is brought to the enclosure and the PTT line is interrupted, thus preventing you from transmitting with the converter in the line. If your rig is conventionally wired (Fig. 6) with the PTT line going directly to a relay and the 12-volt line, you can even pick up the power for the converter from the PTT line since the converter draws less current than needed to energize most relays.

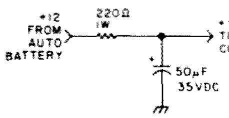

Fig. 4. Noise filter.

Possible Problems and Cures

If you have never built anything at VHF, this could be a good first project. Remember that Murphy's Law applies to all things, and especially at VHF the law states, "Resonant Circuits Usually Don't." Therefore, you might have to add a turn, cut a turn, squeeze the coil, or spread it out to resonate the input and output of the mixer.

Dual-gate FETs, especially those capable of VHF operation, also like to oscillate at weird and wonderful frequencies. If this happens, you will notice a large increase in noise when you connect the converter to your rig. You also might notice fragments of conversations, music, and general instability. The usual cure is to add a ferrite bead by unsoldering the gate leads of Q1 and Q2 and slipping the gate lead through the hole in the bead. Usually one bead per FET is enough, although you will have to try yourself to see which of the two gate leads cures the problem. Alternately, a 100-Ohm, ¼-Watt resistor could be added in series with the gate lead.

A problem of a different variety is faced by most hams—obtaining parts (see Parts List). Most of the parts used in the converter are not critical and are available at your local Radio Shack store.

Miniature variable caps can be a problem. The Calectro line is available at many independent electronics supply houses. Jameco Electronics is another source, at 1355 Shoreway Rd., Belmont CA 94002.

In mixed average terrain, the weather stations are usually good for over 25 miles, although 40- to 60-mile coverage is not unusual. If you are in a very hilly area or well out of the coverage, you could add a preamp such as the standard one in the ARRL handbook. One or two turns will have to be taken off the input and output coils of the preamp.

Want to hear the weather? At home or in your car? Two FETs plus a few hours work and you can make your two-meter rig do double duty. ■

Kill Power-Line Interference

You don't have to be a big-game hunter to find the source of that annoying noise. All you need is your rig and your good hamming habits.

Since 1973, I have been employed by an electric utility company. One of my principal responsibilities has been to investigate power-line interference problems affecting customers. This has involved over 1800 complaints concerning reception of TV, AM radio, FM radio, Citizens Band, and amateur radio. Having had this experience, I would like to suggest a few things to my fellow amateurs to aid in the correction of many of their interference problems without having to request outside help.

The amateur affected by interference has some major things going for him:

1) He is available when the interference is occurring.

2) His station probably has far superior sensitivity and selectivity than the broadband receiver and omnidirectional antenna which some investigators use.

3) He has a working knowledge of radio principles and can make up an accurate and meaningful log of interference characteristics to see if a pattern develops.

Elaborating on the third point, experience indicates that at least 60% of all interference complaints are not due to power lines but are caused by consumer devices. By far the greatest offenders in producing interference are arcing contacts such as those found in all types of thermostatic devices. If interference is of an intermittent nature without a relationship to weather conditions, one can say with some certainty that it is being caused by a device indoors and, most likely, that that device will contain a thermostat of some kind or another.

Two of the most difficult problems in locating these culprits can be handled by having someone there while the interference is occurring, and also by determining the existence of a pattern. This is where an accurate log will help with your efforts in locating interference either on your own or with the help of an investigator.

Some of the devices that we find responsible most often include:

- *Oil burner aquastats*, usually on for 10–15 minutes every hour or so depending on the demand for heat and hot water. Quite often, one will assume that this is not the cause because the trouble clears once the oil burner is ignited. Since this interference is caused by the aquastat, the noise can and probably will occur just prior to ignition or, more rarely, just as the burner goes off.
- *Aquarium heaters* have the characteristic of being on and off somewhat more frequently, usually every 20–40 seconds throughout the whole day and night.
- *A heating pad* is another device found to be troublesome quite often. Fortunately, they seem to interfere every few seconds with a somewhat rhythmic pattern. One problem with some heating pads lies with the controller switch positions: high, medium, off, and low. Most people will, without thinking, turn the controller to the last position instead of to the off position. This practice causes the pad to cycle on and off almost continuously, resulting in arcing and eventual failure of the thermostat contacts. For the same reason, do not be fooled into assuming that heating pads cause interference only at night!
- *Door-bell transformers* are another common cause of trouble, with a sound very similar to the heating pad: on and off over a short time period (but not quite so rhythmic). These transformers are usually located in a basement or crawl space where the temperature near the device is higher than normal. With the power applied continuously to the transformer, the temperature rises and the internal thermal cutout operates long enough for the transformer to cool down. Once it reaches a safe operating temperature, power is restored and the process starts all over.
- A few others are *older refrigerators* with heated butter conditioners, *heat tapes* used to prevent pipes from freezing, and *dimmer switches*, where the interference varies with the applied voltage to the lamps.

One more worth mentioning that will vary with the weather conditions is the *electric fence* with its rhythmic on and off cycle. Even if you live in a metropolitan area, do not rule this culprit out, as I have located them in the strangest places when people want to confine their household pets.

Locating these sources can be fairly simple, but a good piece of advice is to check at home first, just to save some red-faced embarrassment with your neighbors. Look the list over and see if any of my descriptions fit the bill. If so, next time the interference starts, unplug or shut off the power to the suspected device. If it stops, that is it, and you can take whatever corrective measures are necessary. One note of caution: Interference may not start right after power to the suspected device is restored; the device may have cooled down and will take a short rest before it starts driving you nuts again.

If you do not recognize any of these as your problem, while the main interference is on, go to your service panel and shut off the main while listening to the interference on a portable radio tuned between stations. Even an AM radio will usually suffice here, since spark noise is broadband. If the noise stops when you shut off the power, the cause is something fed from your panel box. Next

time it is on, proceed to the branch circuits and interrupt them one at a time until it stops. Then investigate what is fed from that circuit and you can track it down to the defective device.

If the interference should remain while your power is interrupted, the problem is external to your home. A short walk around the neighborhood is in order. Listen to your portable radio for the peak, or point of loudest interference. Avoid holding your radio near guy wires, down grounds, etc., as this may result in a false reading due to the increased coupling to your antenna. Once you have determined the home with the highest noise level, you will have to get permission from the owner to interrupt his power at his panel box.

A little tact goes a long way here, and you might ask him if he is having an interference problem with *his* radio or TV. Remember that the intensity of the interference will decrease as we go up in frequency, and if your neighbor has UHF TV, for him the problem may be non-existent or very mild. Also, the picture will be affected due to its being amplitude modulated and the sound being FM. Try not to accept his word that he is not having any trouble since he may be listening to a very strong local AM radio station which could mask the interference. In other words, try to look and listen for yourself. Most of the offending devices I have found have been within about two blocks of the complainant's location.

Should you feel that the problem is not a consumer device, you may want to take note of the weather conditions when the interference occurs. The chances are that if the problem is caused by a power line, interference that occurs on dry, sunny days will not be present when the weather is rainy or humid, and vice versa.

Since your receiver has tremendous sensitivity, a small micro spark along the power line can result in a great deal of interference. One of the problems we find often is a hardware condition where lag screws, bolts, washers, and other pole hardware loosen slightly, resulting in microsparking. This type of spark is seldom visible to infrared gear since there is very little heat produced, but oh what a racket in the radio spectrum!

Quite often, hardware problems will show up only on dry, cold days, since in wet weather wooden poles absorb some water, swell out, and, in effect, tighten the hardware. This particular problem can be very difficult to correct 100 percent due to the number of poles that may be affected. Also found troublesome are lightning arrestors, disconnect switches, pole grounds, neutral connections, and, of course, tree contact, kite strings with metallic cores, and other such foreign objects.

If you suspect the power line after you have made a careful, accurate log, including frequencies affected, weather conditions, temperatures, and dates and times of occurrences, for safety's sake do not try to locate the trouble by making any direct or indirect contact with the power line. Do furnish your power company with as much information as possible. Doing so demonstrates two major things to the investigator: your concern for the situation and your knowledge of power-line interference. Patience and perseverance are the two main prerequisites for the solution to these interference problems.■

ST. PAUL MN
JUN 4

The North Area Repeater Association will sponsor the Amateur Fair, a swapfest and exposition, on June 4, 1983, from 6:00 am to 6:00 pm, at the Minnesota State Fairgrounds in St. Paul MN. Admission is $4.00 and children under 12, accompanied by an adult, will be admitted free. Features will include an inside flea market but space is limited and available on a first-come, first-serve basis and tables will not be provided. There will be demonstrations, exhibits, booths, an outdoor flea market, and on Friday, June 3rd, free overnight parking for self-contained campers. There will be food concessions inside and outside, and free parking will be available. Talk-in on .25/.85 or .16/.76. For more information or dealer inquiries, write Amateur Fair, PO Box 857, Hopkins MN 55343, or call (612)-420-6000.

GUELPH ONT CAN
JUN 4

The Guelph Amateur Radio Club (VE3ZM) will hold the 9th annual Central Ontario Amateur Radio Flea Market and Computerfest on Saturday, June 4, 1983, from 8:00 am to 4:00 pm, at Regal Hall, 340 Woodlawn Road West, Guelph ONT. Admission is $2.00 and children 12 years and under will be admitted free. Vendors must pay an additional $3.00. Doors will be open to vendors only from 6:00 am and a quantity of 3' × 8' tables will be available for rental for $5.00 each. Features will include commercial displays, surplus dealers, computer software and hardware, indoor and outdoor displays, and a refreshment concession. Talk-in on 146.370/146.970 (VE3KSR), 147.960/147.360 (VE3ZMG), and .52/.52. For further information contact Al Krist VE3KVI at (519)-821-4337, Henry Christiansen VE3BYU at (519)-743-9022, or write VE3ZM, PO Box 1305, Guelph ONT N1H 4M9, Canada.

GRAND RAPIDS MI
JUN 4

The Independent Repeater Association will hold its annual Hamfestival on Saturday, June 4, 1983, from 8:00 am to 4:00 pm, at the Wyoming National Guard Armory, 44th Street, just east of the US-131 expressway. Admission is $3.50. Free table space will be provided to all sellers and dealer setups will be at 6:00 am. Programs will include ATV, satellites, QRP, DX, a CW rx contest, computers, technical upgrade course, MARS, and a shack-photo contest. Talk-in on 147.165/147.765. For advance table reservations or for more information, call John Knoper KC8KK at (616)-534-5501, or write IRA, 562 92nd Street SE, Byron Center MI 49315.

SALINA KS
JUN 4-5

The Central Kansas Amateur Radio Club (CKAR) will hold the 3rd annual Kansas State ARRL Convention on June 4-5, 1983, at the Red Coach Inn Convention Center, West Crawford and I-135, Salina KS. A free flea market will be held, rain or shine, in the parking lot adjacent to the Center. Other features will include programs on both days for hams, non-hams, and ladies, including a technical program involving amateur radio presented by Jerry Hall from ARRL headquarters. On Saturday evening there will be a banquet and entertainment. For further information, send an SASE to Bill Ringquist KAØCUF, RR #1, Box 155, Gypsum KS 67448.

QUEENS NY
JUN 5

The Ebonaire Amateur Radio Society will hold its 2nd annual hamfest/flea market on Sunday, June 5, 1983, from 9:00 am to 3:00 pm, at Southern Queens Park, 119-09 Merrick Boulevard (near the St. Albans Veterans Hospital), St. Albans, Queens NY. Buyers' donations are $2.00 and each exhibitor's space is $4.00. There will be cover if it rains, and free parking. Talk-in on 145.35/144.75 and 146.52 simplex. PO Box 498
Quakertown PA 18951

I would like to hear from owners of the Timex Sinclair 1000 who are using it for RTTY, CW, and SSTV.

William Alzaga XE1WAC
PO Box 26 Suc. A
53100 CO Satelite
Mexico

(So would we!—Eds.)

I need the schematic, parts list, and alignment information for two Heath frequency converters, the SBA300-3 (6-meter) and the SBA300-4 (2-meter). I will pay all costs or copy the manuals and return them.

Robert Schlegel N7BH
2302 286th St. East
Roy WA 98580

I would like to obtain an original or a copy of the manual for a 1946 National receiver, number NC-2-40D. I also need *Single Sideband for the Radio Amateur*, published by the ARRL. I will pay all costs.

Robert L. Schreiber
341 Anlen Ave. #2
Glendale CA 91203

I am looking for the manual and schematic for a Demco Demon Fifty CB amplifier; I also need 10-meter conversion information for it. I will pay all costs.

Bill Edwards N8ARW
1930 Youll St. #30
Niles OH 44446

I need manuals, schematics, or other information on the following equipment: TMC low-frequency multi-coupler, model LMC-10/70U; CEI receiver, type 591; CEI signal monitor, type SM-9303A; Northern Radio Company volume- and current-level indicator, type 254, model 1; Northern Radio Company line amplifier, type 103, model 1; Hammarlund SP-600 VLF; and Collins antenna tuner, type 180L-3. I will pay for expenses.

Richard M. McClung WA6KNW/AAT6XB
6106 SW Summit
Lawton OK 73505

I have a Ballantine model 1066S oscilloscope (also known as an AN/USM 398). I would like to borrow a service manual for copying. I will pay all shipping costs.

Kan Cubilo WB8DOI
215 Huron Apt. A
Oscoda MI 48750

Wanted: maintenance manual for the AN/ART-13. I would also like to hear from anyone who has converted this unit to single sideband.

E. Patrick Herrigan N9AVO
5165 S. Magellan Dr.
New Berlin WI 53151

I need manuals and schematics for a Lafayette HA-800 receiver. I will gladly pay shipping and copying costs.

Philip Birdsong
1613 Whippoorwill Dr.
Lawrenceburg TN 38464

FUN!

John Edwards KI2U
78-56 86th Street
Glendale NY 11385

THE YEAR THAT WAS—1976

Last night, I once again played the videotape of my favorite movie, "So Goes My Love," the story of Hiram Percy Maxim W1AW and his family. You know, no matter how many times I screen this fine film, I never get tired of it. It's just a shame that the copyright laws prevent me from making copies of the film for you readers. It's an amateur-radio classic.

Every ham who has seen this motion picture seems to have his favorite scene. I don't know about you, but my favorite part is where Don Ameche (HPM's pop) gives his pal some phosphorescent hair cream so that he can woo his girl friend in the dark. Wow! Old Hiram must have had quite a family. The only time my dad ever glowed was when he had a few too many Rheingolds at the company picnic. I wonder if they still have any of that ointment in Newington? The stuff would be great to smear over a tower when you have to make emergency repairs during a dark contest night.

This month's topic is the year 1976. You remember 1976, don't you? Lots of big happenings that year, both within ham radio and the world at large. If 1976 was a good year for you, here's hoping this month's FUN! brings back some fond memories. If not, enjoy the puzzles anyway.

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1) The year's big celebration
7) QTH ________ Flushing NY
8) Unit of resistance
10) Thailand prefix
11) Programmable memory chip (abbr.)
13) Ham satellite
15) 5-land state or 6-land city (abbr.)
16) Certain type of transistors (abbr.)
17) Electrons in a circuit; river
19) Phone turnover
20) Peru prefix
21) 1976 presidential contestant
22) What many spouses regard ham rig as
23) Former DM-land (abbr.)
24) 2-land state (abbr.)
25) Bunny hunt (abbr.)
27) To accomplish
28) Glass ________
31) Ireland prefix
32) Hams affected by '76 rule changes

Down

1) Messy solder ________
2) Shack tools made first appearance in 1976
3) *73* state
4) Cut antenna wavelength
5) See 24 across
6) Operates 13 across
9) 1976 centennial state; host to that year's national convention
10) Ecuador prefix
12) Ham greeting (abbr.)
14) After contest: ________ wood
16) The Feds (abbr.)
17) See 21 across
18) Old-timer: prospective hams should ________ dues
19) Made Prog Line rigs (abbr.)
20) ARRL snitch (abbr.)
22) Teach hams
24) Organized on-air group
26) What you're reading
27) Canadian ham bosses (abbr.)
29) Tube amplification factor
30) Household power (abbr.)
31) Spain prefix

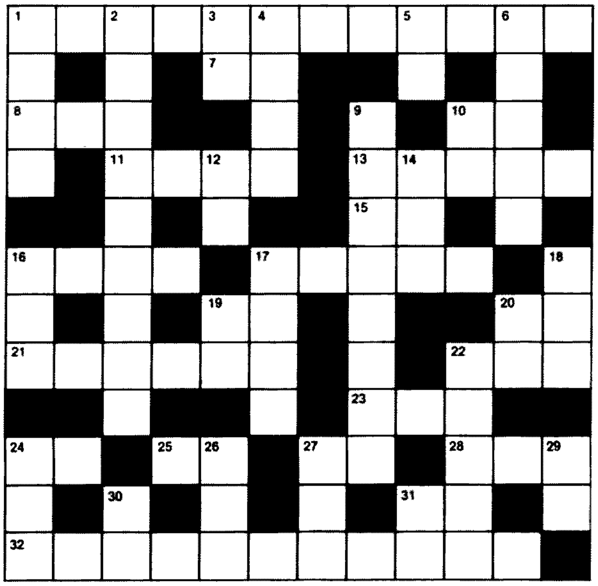

Illustration 1.

ELEMENT 2—MULTIPLE CHOICE

1) What notable contribution to amateur radio did Al Katz K2UYH make on July 29, 1976?
   1) He took part in the first intercontinental OSCAR QSO.
   2) He established the first DX net on 20 meters.
   3) He became the first amateur to qualify for the Worked All Continents award via EME (Earth-moon-Earth) communications.
   4) He became the first ham to work Africa on 2 meters.
2) When the Viking spacecraft landed on Mars, the Jet Propulsion Laboratory Amateur Radio Club relayed its photographic transmissions to amateurs via slow-scan television. What was the special event callsign used, and why was it unique?
   1) The call N6V was the first 1X1 amateur callsign ever issued by the FCC.
   2) The call WMARS was the only amateur callsign ever issued without a numeral.
   3) The call W6 was the shortest ham callsign ever issued.
   4) None of the above.
3) During 1976, the FCC:
   1) Eliminated the requirement to ID as "mobile" or "portable."
   2) Raised the Novice power ceiling from 75 to 250 Watts.
   3) Eliminated the Conditional-class license.
   4) All of the above.
4) In 1976, the first ham station was installed at UN headquarters in New York. Its callsign was:
   1) 4U1UN 2) K2UN 3) WA2MJK/4U1 4) 4U1ITU
5) During the 1976 Montreal Olympics, the official amateur station was:
   1) VE2OLY 2) VE2MTL 3) CZ2O 4) MØNTL

ELEMENT 3—SCRAMBLED WORDS

HCTAPOATU	LECHQUS	FFRATIC	UBLAN
IDESENOT	TEN	RATEX	

ELEMENT 4—TRUE-FALSE

	True	False
1) A new amateur radio magazine (now defunct) introduced in 1976, was titled *Ham Radio Perspectives*.	____	____
2) In 1976, all currently-licensed Novices received Technician-class operating privileges.	____	____
3) The famous "WARC 76" conference gave US hams three new bands.	____	____
4) WL2USA was a special-event station based at the Statue of Liberty.	____	____
5) Among the prominent amateurs to die during 1976 was Dr. Webley Webster W1QSR, inventor of the repeater courtesy tone.	____	____
6) During 1976, the Japan Amateur Radio League celebrated its 50th anniversary.	____	____
7) It was during 1976 that the FCC took the "N" out of Novice callsigns.	____	____
8) Special "bicentennial callsigns" allowed US hams to identify with such exotic calls as AD2IBE and AA2MFR.	____	____
9) Two OSCAR satellites were launched during 1976.	____	____
10) The first ham to work all states on 2 meters completed his effort in 1976.	____	____

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—3 WAC the hard way.
2—1 Along with sister station N4V.
3—4 Busy year in Washington.
4—2 That was before the UN was a "country."
5—3 And you thought "strange calls" were a very recent development!

Element 3:
(Reading left to right): AUTOPATCH, SQUELCH, TRAFFIC, BALUN, and SIDETONE, NET, EXTRA.

Element 4:
1—False *Ham Radio Horizons*.
2—False It was the other way around.
3—False It was "WARC 79."
4—True During the 1976 Thanksgiving weekend.
5—False W1QSR is just a figment of your columnist's sick imagination.
6—True And it was attended to by much celebration.
7—True Marking the end of distinctive Novice calls.
8—True A taste of calls to come.
9—False No OSCARs were launched in 1976.
10—True Dick Hart KØQMS was the ham.

SCORING

Element 1:
Twenty-five points for the complete puzzle, or one-half point for each question correctly answered.

Element 2:
Five points for each correct answer.

MICROWAVE
ATV TRANSMITTER

2.3 To 2.45 GHZ. 75 MW. input
Input video from camera or computer

Element 3:
Four points for each correct answer.

Element 4:
Two and one-half points for each correct answer.

How well have you kept the spirit of '76?

1-20 points—Licensed in 1977.
21-40 points—The body is willing but the spirit is weak.
41-60 points—The mists of time obscure much.
61-80 points—You still drink Billy Beer.
81-100+ points—"Keeper of the Flame!"

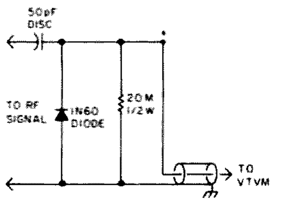
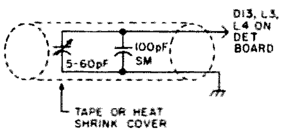
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*

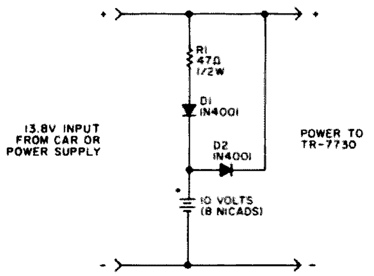


A SIMPLE RF PROBE FOR A VTVM: Your VTVM can measure peak voltage up to 200 MHz by using this probe. The maximum rf that can be measured is determined by the diode; with a 1N60, the probe is limited to 30 V. To increase the capacity, substitute a higher-voltage small-signal-detector diode. Be sure to house the circuit in a metal enclosure and use shielded wire. —Ed Schilling K5RSO, Fairfax VA.

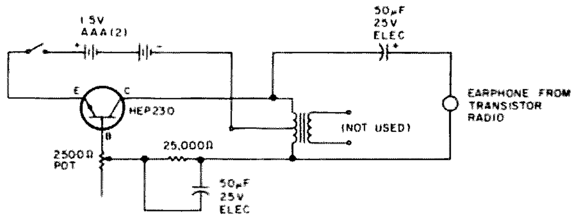


IMPROVING IC-730 SELECTIVITY FOR RTTY: This temporary modification enables the IC-730's CWN filter on LSB. On the second i-f board, connect the purple jumper from P2 to J7 and the white jumper from P3 to J6. This disables the FL-30 PBT filter and connects the FL-45 CWN filter in USB, LSB, and CW, but not CWN. However, the i-f shift still works. The figure shows a parallel capacitor network which should be connected underneath the detector board to the junction of D13, L3, and L4. The other lead goes to ground through one of the detector board's mounting screws. Keep the leads as short as possible and when you cover the network, leave room to adjust the trimmer. To tune up, put the rig in LSB, tune an incoming signal to 2200-Hz audio, and peak the trimmer capacitor for maximum audio output. You will have to retune as you trim to keep the audio at 2200 Hz. The transmitted and received AFSK tone centers will be about 1500 Hz below the LSB dial reading. Do not use modes other than LSB RTTY while this modification is in place.—Lance Holt N9CDD, Biloxi MS.

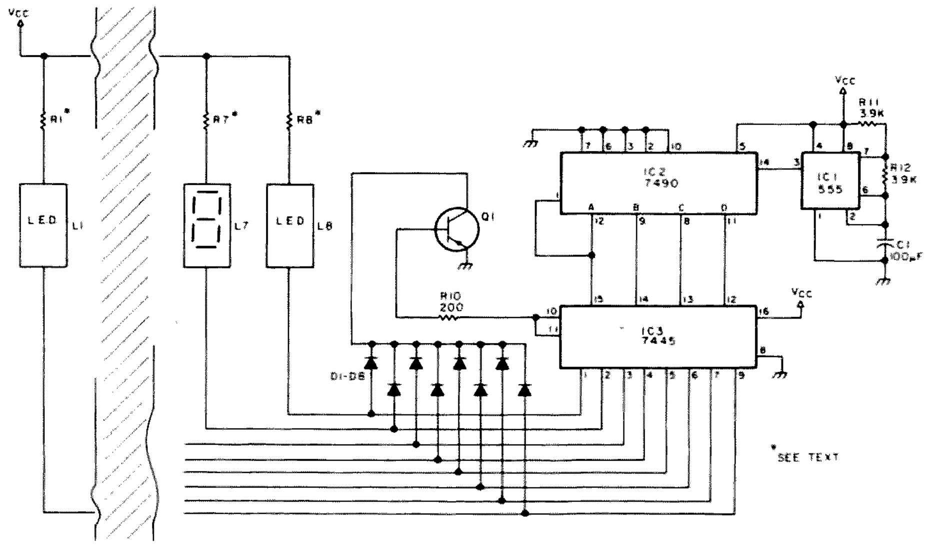
CRYSTAL FREQUENCY SHIFT: Another way of moving a crystal's frequency, besides padding with capacity, is to insert series inductance. Depending on the crystal's characteristics, frequency changes of about 1000 ppm may be obtained with 20 to 30 uH.—Bob Raker WB8ZFF, Cincinnati OH.



MEMORY BACKUP FOR THE KENWOOD TR-7730: This circuit will retain the frequencies in memory while moving the rig from car to house and vice versa. When connected to an external power source, battery B1 is charged through R1 and D1. D1 prevents B1 from discharging when connected to an external supply that is turned off. When external power is removed, D2 provides a current path to the TR-7730 to retain the memory's contents. However, the TR-7730 power switch should be turned off before external power is removed, since B1 will not provide power for normal operation.—William Gouge WB9ALH, Plainfield IN.



THE FISHERMAN'S FRIEND: The click-click sound lures fish to the vicinity, where your bait or lure can do the rest. The transformer is a subminiature type with a 500-Ohm, center-tapped primary and a 3.2-Ohm secondary. Put the circuit in a watertight container and lower it into the water.—Ed Schilling K5RSO, Fairfax VA.



PUT A NAME IN LIGHTS: This circuit will enable you to put a name or callsign in lights using seven-segment LEDs. The display will spell the desired name out sequentially. Select the correct type of LED from a Poly Paks grab bag. Solder the correct leads together to form the letters you want. After mounting the displays on perfboard, calculate the current necessary for the display. Allow 15 mA per segment. Select the appropriate current-limiting resistor. The 7445 can only sink 80 mA, so a PNP transistor is needed to handle the current required to light up the letters. The heart of the circuit is a 555 oscillator into a 7490 decade counter, which is decoded by a 7445 open-collector driver chip. Make your case with two pieces of Plexiglas™ just slightly larger then the perfboard. Space the Plexiglas with four 10-32 bolts, using chrome-plated bolts to make it extra fancy. To cut costs, use a 7-volt supply, series-up a few diodes (1N4001s), and use the .6-volt drop to kill a few volts. An on-off switch is not needed; current consumption is about ½ cent per 24 hours. In one afternoon, you can produce a unique gift! I gave one to a girl in school and now she's my wife!— Alex J. Piechocki, Edison NJ.

NEW PRODUCTS

Trio-Kenwood's TR-7950 2m FM transceiver.

ITC-32 INTELLIGENT TOUCHTONE™ CONTROL BOARD

Advanced Computer Controls has introduced its new ITC-32 intelligent touchtone control board. The ITC-32 addresses the universal need for touchtone control in amateur radio, commercial, and industrial applications with microcomputer-based flexibility and state-of-the-art Mitel tone decoding (no PLLs).

The ITC-32 provides 28 remotely controllable logic outputs and 4 remotely sensed inputs. Morse code or tone-encoded response messages verify command entry and enable remote interrogation of output and input logic states. Eight of the 28 outputs are buffered for high-current/high-voltage drive capability, such as for direct relay drive. The other 20 outputs are TTL compatible levels. The outputs may be commanded singly or in groups, allowing a variety of control possibilities, such as antenna direction, PL frequency, and gain controls. An additional command allows BCD programming for control of remote-base frequency synthesizers.

The logic inputs may be interrogated or may function as alarm inputs, such as for intrusion detect, over-temperature, or flood indication with external sensors. Optional connection to our telephone interface board allows land line control and auto-dial-out on alarm conditions.

The ITC-32 provides several additional capabilities. A basic repeater COR/ID/Timer function is included, so that the board may serve as a low-cost controller for simple repeaters, or for controlling remote receiver links. This capability makes the ITC-32 a perfect low-cost "starter" controller for a new repeater. Later, when you're ready to upgrade to more sophisticated control, you won't have any trouble finding other uses for the ITC-32.

Another feature is selective call decoding for use in the shack. The ITC-32 can keep your receiver silent until someone dials your touchtone access code to contact you, in addition to providing remote "home control" over a repeater or simplex frequency.

The ITC-32 will find amateur-radio applications in repeaters, remote receiver sites, remote bases, and home control. It's based on the popular Vector 4.5" x 6.5" 44-pin-edge-connector format, for easy integration into any system. It operates from a single 8- to 14-volt power supply.

For more information, contact *Advanced Computer Controls, 10816 Northridge Square, Cupertino CA 95014; (408)-749-8330.* Reader Service number 481.

2-METER MOBILE TRANSCEIVERS

The latest additions to the Trio-Kenwood line of 2-meter mobile transceivers are the TR-7950 and the TR-7930, identical in features except for rf output: a husky 45 Watts for the TR-7950, and a more modest 25 Watts for the TR-7930. The most notable features include a large, easy-to-read LCD display, 21 multi-function memories, automatic offset, programmable priority channel, memory and band scan, long-life lithium battery memory backup (est. 5-year life), built-in 15-key autopatch, and a host of accessories, including an optional 3-frequency sub-tone unit, with keyboard-selectable sub-tones.

Additional information on these models may be obtained by contacting the local Kenwood dealer, or by writing to *Trio-Kenwood Communications, 1111 W. Walnut St., Compton CA 90220.*

SUPPLEMENT TO *SW HOBBY EQUIPMENT REVIEW*

The International DXer's Club of San Diego has announced the new 1983 supplement to its popular *SW Hobby Equipment Review*. This supplement is 194 5½" x 8½" pages in loose-leaf form. A quarterly update also is available on a subscription basis, as well as a leatherette ring binder with the club's logo. The first update in March will contain full coverage of the new Icom and Kenwood.

For additional information, contact the *International DXer's Club of San Diego, 1826 Cypress St., San Diego CA 92154; (619)-429-9728.* Reader Service number 487.

NXL-1000 INDOOR SHORTWAVE ANTENNA

Contemporary Electronic Products has announced their innovative new NXL-1000 indoor shortwave antenna. Unlike other active indoor antennas, the NXL-1000 employs a Faraday shield for maximum rejection of man-made noise, which is so often a problem for the amateur or SWL. In addition, the NXL-1000 has a built-in crystal calibrator with selectable 1-MHz and 100-kHz markers. This is a great help with uncalibrated or poorly calibrated receivers.

The NXL-1000 covers the 1.5-30-MHz range in three ranges. A high-Q selective circuit provides excellent rejection of unwanted frequencies. This can be a valuable asset with receivers having poor front-end selectivity or marginal image rejection. Internally generated noise, a problem with some active antennas, has been substantially reduced in the NXL-1000.

The NXL-1000 can provide performance comparable to a long-wire antenna and allows even better reception than an outdoor antenna in high-noise environments. By adjusting the orientation of the loop via the AZ-EL mount, local signals and noise can be almost totally nulled out.

The NXL-1000 can be conveniently placed on a desktop. The cabinet measures just 3 by 5-1/4 by 5-7/8 inches (HWD). The loop is only 12 inches in diameter. For additional information contact *Contemporary Electronic Products, PO Box 570549, Miami FL 33157.* Reader Service number 480.

NEW RTTY PUBLICATIONS

Universal Electronics, publisher of RTTY station lists, has added two new titles to its publications: *Radioteletype Press Broadcasts* and *World Utility Frequency and Call Sign Guide*. These books contain the latest information on RTTY stations around the world.

Radioteletype Press Broadcasts is divided into two lists for easy access. The first list is in chronological order for each half-hour segment of the 24-hour day. Each segment lists the agency that will be on the air at that time. The second list gives detailed time and frequency schedules by press agency. Also included is an alphabetical listing of agencies around the world, with an accurate cross-reference listing by country.

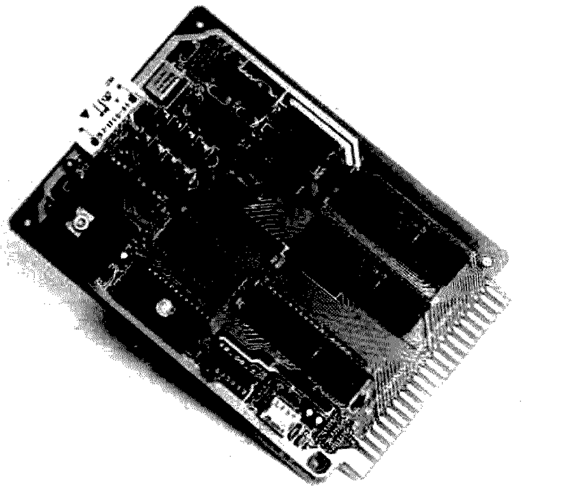
World Utility Frequency and Call Sign Guide gives detailed information on many utility stations around the world. Both books are printed in an 8½- x 11-inch format for quick reference and are guaranteed to contain the latest data available anywhere in the world.

For more information, contact *Universal Electronics, Inc., 1280 Aida Dr., Reynoldsburg OH 43068; (614)-866-4605.*

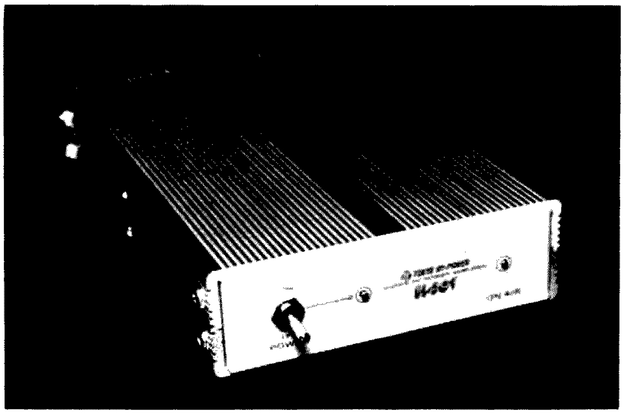
VHF LINEAR AMPLIFIER FROM ENCOMM

Tokyo Hy-Power Labs, Inc., has announced its new VHF linear amplifier, the 30-Watt HL-30V, for use with portable 2-meter radios.

The HL-30V is a high-quality, easy-to-use, 30-Watt VHF amplifier. It is designed to be driven to maximum output power with only 3 Watts drive from hand-held radios. It will take 1-5 Watts drive, with 1 Watt delivering about 10 Watts output. This neat little amplifier is perfect for turning your hand-held



ITC-32 intelligent touchtone control board from Advanced Computer Controls



Encomm's HL-30V VHF linear amplifier.

The Apollo Q-1 satellite receiver/downconverter from National Microtech, Inc.

2-meter transceiver into a powerful mobile rig (or base station with appropriate power supply).

This versatile linear amplifier operates on 13.8 volts dc and draws approximately 4 Amps maximum during transmit. It utilizes carrier-operated switching-(COX) with no delay and has SO-239 connectors. The HL-30V measures approximately 4" W × 6" D × 1" H (100 × 158 × 30 mm) and weighs 520 grams.

Also available from Encomm is the HL-32V. This amplifier is similar to the HL-30V except it has an FM/SSB switch to allow SSB/CW operation and a high/low power switch which cuts output power by one half.

For more information, write *THL Sales Department, Encomm, Inc., 2000 Ave. G, Suite 800, Plano TX 75074; (214)-423-0024.* Reader Service number 482.

SMR WEATHER FACSIMILE RECORDERS

Two weather facsimile recorders recently introduced by SMR, Inc., can take the guesswork out of weather forecasting for the cruising yachtsman.

The SMR SF-505 offers numerous features. The unit provides receiving capabilities on six crystal-controlled channels with a frequency range of 3 to 24 MHz. Designed for vertical or horizontal mounting, the compact weather recorder offers approximately 29 hours of continuous receiving time on one roll of paper. Other features of the SF-505 include a heavy-duty cast aluminum cabinet, automatic and manual phasing, 120-rpm paper speed, vfo spot and fine tuning, built-in signal meter, and contrast control.

The SMR SF-502 is a sophisticated weather recorder that features 12 channels in three different frequency bands. Frequency bands, with four channels in each band, include 3 to 6 MHz, 6 to 12 MHz, and 12 to 24 MHz. Other features include three scanning speeds, multiple voltage capacity, automatic and manual phasing, black and white inversion capacity, crystal-controlled independent synchronizing, vfo spot and vfo fine tuning, built-in receiver, and a cast aluminum housing.

For further information, contact *SMR, Inc., 1401 N.W. 89th Court, Miami FL 33172; (305)-591-9433, FL (800)-432-7142, National (800)-327-6790.* Reader Service number 488.

EX-1000 DESOLDERING HANDPIECE

Automated Production Equipment has announced the Model EX-1000 desoldering handpiece with new improved heater element. The shorter element means shorter solder-travel path, resulting in clog-free operation. The shorter heater also requires less wattage, giving cooler operation for added operator comfort as well as significant energy savings.

For more information, contact *Automated Production Equipment Corp., 142 Peconic Ave., Medford NY 11763; (516)-654-1197.* Reader Service number 484.

SATELLITE RECEIVER/ DOWNCONVERTER

National Microtech, Inc., has announced the addition of the Apollo Q-1 satellite receiver and downconverter to its broad product line. The Apollo Q-1 features push-button transponder selection, automatic polarity control, an audio-in signal-strength meter display, a built-in modulator, and many more features. The Apollo Q-1 is packaged in a wood-grain cabinet with black anodized faceplate. A separate downconverter with integral LNA power block completes the package.

For additional information, contact *National Microtech, Inc., PO Drawer E, Grenada MS 38901.* Reader Service number 483.

UNGAR 9300 SOLDERING IRON USES THERMO-DURIC™ HEATING ELEMENT

A new System 9300 soldering iron introduced by Ungar, Division of Eldon Industries, Inc., uses Ungar's recently developed Thermo-duric heating element, which heats more efficiently and recovers faster than previous models.

The element is nonmagnetic, and the iron conducts static electricity from the tip to a grounded wall plug. Both factors prevent static-electricity damage to microcircuits.

A thinner, cooler handle than those of other models was made possible by the smaller heating element. An operating temperature of 700 or 800 degrees F is determined by the heater, which can be quickly changed. Any of five standard Ungar tips can be used with either heater.

Further information is available from *Ungar, Division of Eldon Industries, Inc., 100 West Manville St., Compton CA 90220; (213)-774-5950.* In Canada: *Eldon Industries of Canada, Inc., 500 Esna Park Dr., Markham, Ontario, L3R 1H5 Canada; (416)-495-9407.* Reader Service number 485.

HAL'S CWR6750 TELEREADER RECEIVE-ONLY RTTY/CW TERMINAL

Hal Communications Corporation has announced the new CWR6750 receive-only RTTY/CW terminal. The CWR6750 is the ideal companion to a shortwave receiver for printing amateur and commercial Morse code and RTTY transmissions. Its small size, the built-in green screen video monitor, and 12-volt operation make the CWR6750 a truly portable unit. The CWR6750 will receive all standard radio-teleprinter speeds from 60 words per minute (45 baud) to 300 wpm (300 baud). Both the standard press Baudot RTTY code and the computer ASCII RTTY code may be received. Stations using the continental Morse code may be received at speeds from 4 to 50 wpm. A computer-style ASCII printer may be connected to the CWR6750 to obtain a full printed copy of all received text. The CWR6750 measures only 10¼ inches wide, 6½ inches high and 11 inches deep. It weighs only 9 lbs. and operates from any 11- to 14.5-V-dc source, drawing 1.6 Amperes. The CWR6750 is easily installed in a camper or boat or right in your own home station because it occupies so little space. Connect the CWR6750 to your shortwave receiver and see what you've been missing.

Hal's CWR6750 Telereader receive-only RTTY/CW terminal.

For more information, contact *Hal Communications Corp., Box 365, Urbana IL; (217)-367-7373.* Reader Service number 486.

NAVAJO CALL-LETTER BELT BUCKLE

Lee-Art, Inc., has introduced an inlaid call-letter belt buckle hand-crafted by Navajo Indians. (The 73 logo is also available.) The nickel-silver buckle is highly polished and beautifully inlaid with genuine stones. The call letters may be inlaid with blue torquoise, rust coral, white abalone, mother-of-pearl, or ironwood brown. Each buckle has four lightning bolts carved and inlaid in yellow. The entire buckle is enhanced with carved designs around the call letters, the lightning bolts, and the outside edge of the oval, and carved feathers add a further touch. The buckles come in two sizes, medium (2.6" × 3.6" oval) and large (3" × 4" oval).

For further information, contact *Lee-Art, Inc., 112 N. Main Street, Shamrock TX 79079.*

REVIEW

FLICK OF THE SWITCH— KENWOOD'S TS-430S

Over the past several years, various solid-state HF rigs have been introduced to the ham marketplace. Some were small, some were large, and some recent units offered digital frequency readout, i-f shift, notch filtering, and even a memory frequency. Some of the rigs are only memories themselves.

This weekend I had the enjoyable use of Kenwood's most recent entry, the TS-430S. This small box is the most fascinating ham radio I have ever seen, and I have seen and worked on about all there is on the market. In addition to being a very state-of-the-art ham rig, the TS-430S is also a great SWL receiver.

The TS-430S is all solid-state with digital frequency readout, dual vfo's, and 8 continuously programmable frequencies, and that is just for starters.

Construction

State of the art requires careful planning and engineering in the design of a reliable and easy-to-operate piece of equipment. The TS-430S is an excellent example of state of the art.

Kenwood has maintained their usual grey colors on the new unit, and has, fortunately for my tired eyes, retained the blue fluorescent digital frequency readout. The front panel of the TS-430S is loaded with controls, 38 of them to be exact. But don't let all that scare you. This is a "no-tune" rig. Basically, you select the frequency and mode, set the volume and mike levels, and you are ready to go on the air. The other controls are used in selecting accessories such as the noise blanker, i-f shift, attenuator, etc. Also on the front panel is a small keyboard. This is the heart of the memory and program system. From here you can preselect frequencies and modes of operation to be later utilized at the flick of a switch.

Inside, the rig has a very clean layout with separate boards for each major functional block, with plug-in wiring harnesses used between them. Space has been left for user installation of optional filters and the FM unit (FM-430). The rig appears to be a technician's dream. There is even a provision for 10-Hz readout, requiring the clipping of a wire, and WARC band usage by clipping another wire. These operations are well documented in the well-written owner's manual.

On the rear panel is a very large heat sink to cool the finals, and a fan has been installed to aid in this cooling. Unlike other solid-state rigs with fans that run during all transmissions, this fan only operates when the temperature of the heat sink exceeds 122°F (50°C), and then it is ultra quiet.

Operation

The operation of the TS-430S proved to be more than expected from such a small package. Most of my normal hamming is on 40 and 75 meters, so naturally I started there with the new rig. Initially, I programmed the frequencies of nets I operate on into the rig, and then with a flick of the switch I was able to move from one frequency to the next. It is interesting to note that when programming a frequency into the unit, the mode (USB, LSB, AM) is also programmed. This is nice when moving from a 20-meter net to a 40-meter net. All you have to do is flick the switch. Early in the day, on 75 meters, I set the unit to scan the memory frequencies. This allowed me to monitor activity on each of several nets. I then set the squelch (yes, I said squelch) above the noise threshold and enjoyed quiet until a net became active. I note here that each programmed frequency is scanned; however, when a busy frequency is encountered, the unit will continue to scan unless you transmit, after which it will continue to scan.

Everyone I talked with remarked about the high quality of the audio signal. All said it was great, and more than one said it "must be a Kenwood." No station was apprised of what rig I was running until after signal reports had been exchanged. One glitch I found was that when using the speech processor, you must be very careful not to over-drive the unit, as distortion will result. This would no doubt vary depending upon the mike each individual uses. The only other glitch will be covered shortly.

Speaking of the speech processor, it worked quite well on DX. I found it particularly useful on 10 meters when the band was going out. Its use was the difference between QSO and no QSO.

On 40 meters SSB at night, the home of all those international broadcasting stations, I was able to enjoy easy communications; just a twist of the notch filter was needed. Herein lies the other glitch. The notch filter, while very effective, is very sensitive in adjustment. I found that I was able to silence a 20-dB heterodyne and work an S9 signal. Notice I said silence, not reduce. . . silence!

I made several DX contacts on 40 meters using split frequencies. Very easy to accomplish when you have two vfo's. I also found CW operation to be quite good, and this rig had no optional filtering installed. I utilized the i-f shift and notch filter. I have not mentioned the VOX or attenuator since they are commonplace on most rigs and work well on the TS-430S.

I had a guest over one evening, and since he is an avid SWLer, I turned the controls over to him. First he programmed in the frequencies of his favorite stations, and then we memory-hopped all over the world at the flick of a switch. The sensitivity and selectivity were judged to be just short of fantastic. Surprisingly, there are no apparent shortcomings or compromises made in this versatile little rig. It is equally suitable for SWL or ham. We did, however, agree that the 6-kHz optional filter would be an asset for SWL.

I am now able to listen to Radio Australia while I have breakfast, and the now famous

Transmitter coverage	160 to 10 meters
Receiver coverage	150 kHz to 30 MHz
Modes	SSB, AM, CW, FM
Size	10.6" × 3.8" × 10.8"
Weight	14.3 lbs.
Transmitter power	250 Watts PEP
	200 Watts CW
	60 Watts AM
Receiver sensitivity	SSB— .25 microvolts (160-10 meters)
	AM— 2.5 microvolts (160-10 meters)
	SSB—2.4 kHz at -6 dB
	AM— 4.4 kHz at -60 dB
Receiver i-f rejection	More than 70 dB (ham bands)
Receiver image ratio	More than 70 dB (ham bands)
Power requirements	13.8 V dc 1.2 Amps on rx, 20 Amps on tx

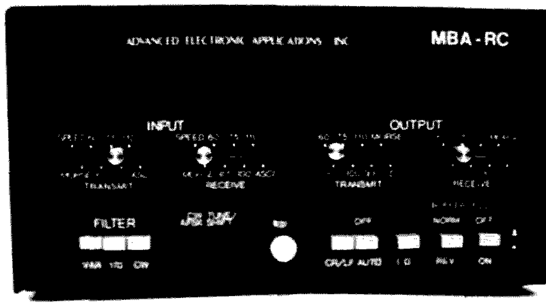
D. The TS-430S—38 controls, count 'em!



AEA's MBA-RC.

flick of a switch switches me to my morning net on 75 meters.

Recap

All in all, I feel that Kenwood has made the TS-430S a real winner. I am able to replace a whole deskful of equipment with this one small rig. Out goes the shortwave receiver, the tube HF rig with its external vfo and digital readout. I did not attempt mobile operation; however, I can see no reason for this unit not being tops in mobile HF operation. It can work 10-meter FM with the installation of the FM-430. Besides, if you get tired of hamming, you could always program your favorite AM band stations into memory and at the flick of a switch listen to music or news (arghhh).

Now I think I'll make a flick of the switch and get back on 75 meters.

AEA MORSE/BAUDOT/ASCII READER/CODE CONVERTER

Can a ham find happiness with a modest dipole antenna and a CW-only rig? Sure he can; just throw in a high-tech accessory like Advanced Electronic Applications' Morse/Baudot/ASCII reader/code converter, the MBA-RC. AEA is no newcomer to the code reader business. For two years they've been getting plenty of raves about their MBA-RO, a read-only converter that was reviewed in the January, 1982, issue of *73*.

Don't let the MBA-RC's lunch-box size fool you. A natural for portable or even mobile operation, it will also hold its own in your home shack. Hookup couldn't be simpler: You'll need a 12-volt power supply (two Amperes or better) and cables to your rig's audio output for receive and to the microphone and key jacks for transmitting. AEA even includes a small kit of connectors to make your life easy. Gone are the days when RTTY operation required a roomful of clanking Teletype™ machines and a special terminal unit.

The MBA-RC consists of two converter circuits, one for transmitting, the other for receiving. The receiving converter accepts an audio input (Morse, Baudot, or ASCII) and outputs your choice of Baudot (serial only) or ASCII (serial or parallel). The transmit converter accepts Morse, Baudot (serial), or ASCII (parallel or serial) inputs and outputs your choice of Morse, Baudot, or serial ASCII either in a two-tone audio signal or transistor-level switching. The ASCII signals can be 110 baud, Baudot speeds are 60, 67, 75, and 100 wpm, and Morse may be 3 to 80+ wpm. Working in parallel with the receive converter output is a 32-character fluorescent display. Differences between input and output speeds are accommodated by a 1000-character buffer. Still confused? Perhaps the block diagram in Fig. 1 will help straighten things out.

All of this power is made possible by using two microprocessors and 43 other ICs. Three circuit boards hold all the parts: one for analog functions, a second for digital chips, and a third for the display and front-panel controls. Even with this modular approach, point-to-point wiring is kept to a minimum to ensure maximum reliability. Good design is backed up by careful construction and a 48-hour burn-in for all units. After the sale, service starts with, but is not limited to, a 90-day warranty.

Despite an impressive array of controls (13 on the front, six on the back), the MBA-RC is easy to operate. Ten minutes after unpacking the box, I was tuning across 40 meters. First I explored the Novice subband where an abundant source of sloppy fists let me check out the unit's ability to copy CW. Just as I expected, the computer reader worked well with only about two-thirds of the signals, failing on the others either because of QRM or poor character formation on the sending end.

Tuning down to 7.080 MHz, I found W1AW spitting out code practice at a brisk 30 wpm, too fast for me to copy without the aid of the reader. A change in speed didn't faze the MBA-RC a bit, with the display's rightmost two characters quickly updated with the new rate. When a jammer showed up frequency, I just tweaked the converter's passband control and missed hardly a letter, confirming my suspicion that the MBA-RC's two-stage active filter (300 Hz to 2 kHz) helped make up for the HW-16's lack of the bells and whistles found on most newer rigs.

I really put the MBA-RC's processing circuitry to the test on 80 meters where I found a few RTTY signals immersed in noise. It took a steady hand and the aid of the converter's LED mark-space indicators to copy anything meaningful. Later, when the QRN subsided, I even found a couple of stations using 850-Hz shifts and got a chance to try the variable shift filtering. Also available but little used is a Normal/Reverse switch for signals that are "upside down."

CW reception using the converter was as good as any I had seen with dedicated readers and better than what you might get with an interface/computer combination. This came as no surprise; the MBA-RC uses the same kind of decoding algorithm found in the MBA-RO. RTTY reception was successful when signal levels were strong, equaling the performance you would expect from a low- to mid-priced terminal unit.

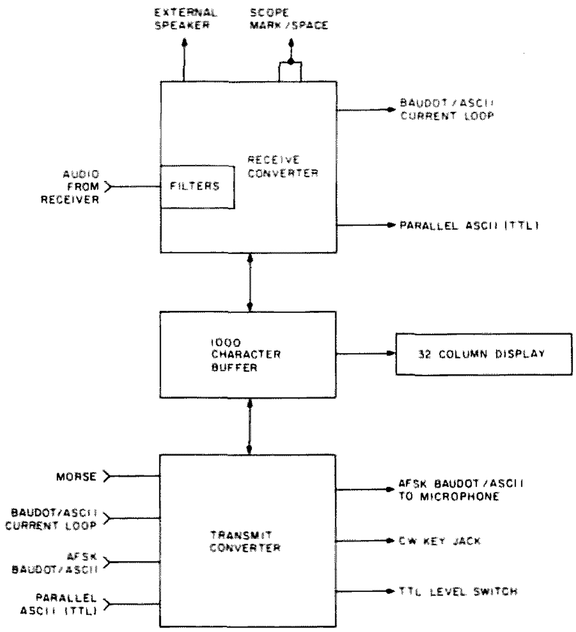

Fig. 1.

Although the 32-character display was long enough to display whole words and some sentences, it still took practice to keep up with its scrolling. Rather than rely on my head for storing information, I learned to use a pencil and paper, jotting down notes as the words marched by. At first I thought the converter was lapsing into gibberish, but later I discovered that the strange symbols I was seeing were just special teletype characters like BELL and CR (carriage return). And although I didn't encounter any, the MBA-RC is programmed to handle several foreign language characters in addition to the usual uppercase alphabet and numerals.

CW and RTTY reception turned out to be the easy part of the review. Limited to a CW-only rig, I couldn't take the quick and dirty way out and use the microphone jack for audio shift keying. My attempts at modifying the HW-16's vfo for frequency shift keying were only partially successful. The instability of the shift was enough to wreak havoc on the receiving end, but not so bad that I couldn't verify the converter's performance.

Using a straight key as an input and RTTY as the ouput, I started by just sending tones to a tape recorder and then playing them back to see how well I did. Luckily, the same forgiving CW-reading algorithim used on receive must be used for transmit, and I managed to prove that if you have a good enough fist, the fellow on the other end won't even know that you're generating RTTY without a keyboard. Of course, there is no provision for sending a carriage return or line feed with Morse code, so you have to rely on the converter to insert this automatically after each line. A nice bonus is the ID buffer. It allows you to store up to 40 characters which can then be used in any output mode. For example, you could load in your callsign and then identify in RTTY, switch to CW out, and identify again in Morse code. The ID capability is used in a similar fashion to set the transmit speed for CW output.

The strange feeling that accompanies sending RTTY via CW is topped only by the use of the MBA-RC as a speed converter for CW operation. You can rip along at 25 or 30 words per minute, storing the excess characters in the buffer, and at the same time hear what was being sent several seconds ago transmitted at ten or even five words per minute.

Moving from the unusual to the ridiculous, consider this possibility: You're receiving CW and printing it out on an ASCII printer driven by the MBA-RC's RS232 port. And on the other end, the station is receiv-

ing ASCII that you generated by typing on a teletype keyboard. The number of combinations and cross-combinations is mind-boggling. A natural for automated operating schemes, the MBA-RC could also find some interesting applications in other fields.

A bit closer to home, "Joe Ham" will find the MBA-RC to be a hassle-free way to get on RTTY. Drawbacks include the 32-character display—it's no match for the full-sized screen that accompanies a computer system. Nor is the MBA-RC's analog signal processing going to give the same performance that you would expect from an expensive dedicated terminal unit. Still, as a stand-alone unit, the MBA-RC offers more flexibility than any dedicated RTTY or computer CW/RTTY system that I know of.

The MBA-RC has a list price of $469.95. For more information, contact *Advanced Electronic Applications, Inc., PO Box C2160, Lynnwood WA 98036.* Reader Service number 476.

HY-GAIN'S TH7DX TRIBANDER

I had always wanted to have monobanders on 10, 15, and 20 meters, not only for the gain of the antennas, but also for the broadbandedness of them. When I saw the specs on the Hy-Gain TH7DX, I knew that I could get close to "the real thing" without having a monster Christmas tree array.

The TH7DX has seven elements in total. Two of these are fully-trapped driven elements. This is how the broadband effect is accomplished. The boom length is 24 feet, the longest element is 31 feet, and the turning radius is 20 feet. The TH7 will take up to a 2½-inch mast and weighs 75 lbs. The maximum wind survival is 100 mph, and the antenna turns just fine with my old Ham III rotor.

Electrically, the antenna claims 22 dB (±5) front-to-back ratio on 20 and 15 meters and 18 dB front-to-back on 10 meters. The maximum forward gain claimed on 20 meters is 8.0 dBi; on 15 meters, 8.7 dBi; and on 10 meters, 9.6 dBi. These gain claims appear to be fairly accurate according to just-calibrated S-meter readings and numerous on-the-air reports. The antenna is dc-grounded for lightning protection and can handle the maximum legal power limit.

Construction

The TH7DX is different than its predecessor, the TH6, not only in that it has one more element, but also in that Hy-Gain has included stainless steel hardware and lots of it! 724 nuts, bolts, screws, washers, tubing assemblies, and other assorted pieces of hardware have to be assembled into this monster antenna. The instruction manual is 22 pages long and includes all the information necessary to easily build the TH7DX, even if you are not technically inclined. The manual is very complete. It includes everything from troubleshooting charts to an extra copy of the pictorial page so that you don't have to constantly flip pages when referring to part numbers during construction. My only gripe is that the manual states that you "should allow at least 7 hours for assembly." This statement is not very accurate, at least for the antenna that I assembled.

Jeff DeTray WB8BTH and I had a perfect weekend to assemble the antenna. The temperature was about 65 degrees for the entire 3 days that it took us (and a few others) to assemble and raise the antenna. Hy-Gain suggests that a large clear area be chosen to assemble the TH7. The area has to be at least 24'×31' and should preferably be a concrete driveway. My location did not afford us the luxury of a paved surface. With this in mind, we paid careful attention to how we handled the hardware. I did not relish the thought of searching the lawn for a lost bolt after all the hardware stores had closed.

The assembly started on a Saturday morning; we put in 8 hours of actual construction time that day. On the following day, we spent another 9 hours on the job, working well into the night "under the lights." Finally, after 17 total hours, the antenna was assembled. Hy-Gain had thought of everything . . . including ropes to install inside the elements to eliminate premature metal fatigue from wind vibrations. On Monday, the tough part came.

My tower at home consists of 100 feet of guyed Rohn-25 sections topped with 20 feet of 2"-o.d. ¼"-wall aluminum tubing for mast. Already installed on the mast is a 2-meter vertical beam on top. Six feet below that is a horizontal 2-meter yagi. The spot I had chosen for the TH7 was well below those antennas at the bottom of the mast, just above the rotor and thrust bearing. It looked very simple from the ground.

All we had to do was hoist the antenna up with the boom horizontal, and use some ropes and the guy wires as guides. After about 2 hours of preparation and horsing it around, we got the antenna close to the top. The elements ran into and got entangled with the lower 2-meter antenna. We had to lower it back down to the ground again and use a different attack. This time around, we hauled it up with the boom perpendicular to the ground. When the boom and first elements got to the top of the tower, where Chris Brown KA1D had been patient during numerous strategy sessions, we manhandled it into place. It may sound simple in prose, but it really was a Herculean task! If it were not for Chris and all the ground crew (WB8BTH, WA2VSN, W1NHJ, and WA1YZN), we would have wound up with an aluminum scrap pile instead of the fine antenna that the TH7 really is.

The TH7 has performed excellently! It is a real pleasure to take full advantage of the bands instead of having to operate only in the portions where your antenna resonates. This is especially important in these days of swr-sensitive transistor finals. The swr curve is just as Hy-Gain states . . . under 2-to-1 for all bands. I would wholeheartedly recommend it to anyone who is looking for a no-compromise tribander.

For further information, contact *Telex/Hy-Gain, 9600 Aldrich Ave. So., Minneapolis MN 55420.*

Photo B. The TH7 begins its slow ascent to the top.

Photo C. At the top of the tower, the TH7 is manhandled into place.

Photo D. Nuts and bolts get a final twist as the TH7 is locked securely into place just above the rotor and thrust bearing.

SEYCHELLES SAGA
V. C. Harvey-Brain ZL1BSO

V. C. Harvey-Brain was the first radio amateur to be licensed in the Seychelle Islands (as VQ9HB) and the *Seychelles Saga* is Harvey's story of how he got to the Seychelles in the first place. It is a cracking good adventure story, and really a saga, as it represents one man's search for his own personal paradise and the achievement of that dream through years of trial and tribulation.

Harvey (as he prefers to be called) began his adventure as the owner of a 36-foot English fishing smack called a Brightlingsea. He was living and working in pre-war England and had decided to chuck it all for a life of seafaring adventure aboard his small boat. So, in the summer of 1939, Harvey and his crew member set sail across the English Channel in the *Brian Boru*, bound for France and its extensive inland waterway to the Mediterranean Sea.

They had very little money, a cat, and enough provisions for a couple of weeks aboard the *Brian Boru*. There was minimal navigation equipment, a few spare parts, and some materials for any necessary minor repairs to sails or engine.

The engine was a gasoline-powered unit from a small pre-war Morris automobile, and its major virtue was reliability . . . it never failed them. By a combination of sailing and motoring, their voyage carried them through France and into the Mediterranean where his first crew, discouraged and helpless, left him. The fight with storms, damage to the boat, the interruption by World War II, adventures in Crete, Malta, and the Red Sea, and even shipwreck are woven into this fascinating story.

V. C. Harvey-Brain must be classed as untiring and unbeatable. Yes, he did achieve his dream; he made it to Mahe, Seychelle Islands, in 1946, where he lived for many years. He accompanied Gus Browning W4BPD to the Andaman Islands. He also has visited and enjoyed DX from Aldabra and other remote spots in the Indian Ocean, which he sailed for years before finally settling down to life in New Zealand and Australia. As ZL1BSO, he alternates his residence between them . . . alive and well, in his seventies.

Seychelles Saga is not a ham radio story *per se*, but it is an incredible tale nevertheless and bears reading for fun and education . . . and perhaps a bit of inspiration as well. With luck, we shall see more of Harvey as he has many more tales to spin for us, and we are hoping that he will tell us something about his hamming and DXpeditions in the pages of *73*.

Special price to hams for *Seychelles Saga* is $8 postage paid, via sea mail, or $12 air mail. Write to *V. C. Harvey-Brain ZL1BSO, 7 Hamilton Road, Surfdale, Waiheke Island, Hauraki Gulf, New Zealand.* Reader Service number 477.

PATHFINDER II SATELLITE TRACKING PROGRAM

When UPS delivered Pathfinder II, it was like an unexpected reunion with an old friend. Pathfinder was and still is a microcomputer software package developed to assist in the location of amateur radio communications satellites. Of course, things had changed since our first meeting in 1981. The name was different, Pathfinder II instead of plain Pathfinder, and the program had been transformed into a slick commercial software package. But I was glad to see that my old friend still retained its fundamental appeal, the eye-catching graphics that earned it the label "satellite superstar" and the cover of the March, 1982, issue of *73*. Pathfinder II runs on an Apple II computer with at least 48K of memory, Applesoft Basic, and one disk drive. Optional but strongly recommended is an Epson "Graphtrax" printer.

First, a caveat: Pathfinder II is designed

to work to track any satellite with a circular orbit. That means it will work with amateur spacecraft like OSCAR 8 and the Soviet "radiosports" as well as non-amateur orbiters, including the NOAA 6 and 7 weather satellites. Pathfinder II, however, is not suitable for tracking satellites with elliptical orbits like the one planned for the Phase III amateur communications satellite.

Why pay Computer Applications for Pathfinder II when you can get it for free by using the listing in *73*? Well, for $34.95 you avoid the aggravation of lots of typing and you get about twice as much software as is presented in the published listing. Another incentive to buy is the package's "polish," including a comprehensive user's manual. With the exception of the high-resolution images and printing routine, *all* of the Pathfinder programs are written in Applesoft Basic. While this makes the program seem slow at times, it also makes it easy to customize. And since Pathfinder II is not copy protected, you can fiddle with a backup disk, leaving the original safe and secure.

Pathfinder II includes a program (also called Pathfinder II) that resembles the magazine version. After entering your longitude and latitude and choosing a satellite (data is pre-programmed for OSCAR 8, RS3-8, and NOAA 6 and 7), this module calculates the horizon, precision, and number of orbits in a 24-hour day. Then the orbit numbers and the equatorial crossings are calculated for a selected date. Next you choose the orbit you want to track and enter the number of intervals at which data is to be calculated (known as subsatellite points). You can choose as many as 120 points per orbit, or more than one per minute for orbits like those associated with OSCAR 8. For each subsatellite point, Pathfinder II computes the satellite's location (longitude and latitude), distance from your location, and the bearing (azimuth heading). If the satellite is visible at that point, the elevation angle is calculated, too.

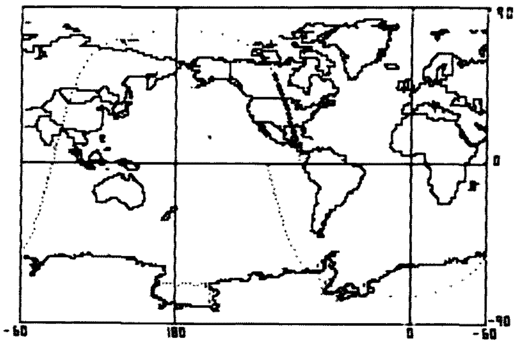

Fig. 1. Pathfinder II provides two real time tracking options. One resembles the illustrations in the March, 1982, 73 and is a map of North America with the states outlined. The second map is a Mercator projection of the world. The orbit shown crosses the equator east of Ecuador before passing through the central United States. Not shown here are several lines of text that accompany the map.

So far Pathfinder II has done what other tracking programs do: generate a bunch of numbers. But the way in which Pathfinder displays this data is unique. Oh, if you're a purist you can get the usual tabular printout, but wouldn't it be nice to see what the satellite is doing? Real Time Track allows you to do just that. Using the Apple's high-resolution graphics, Pathfinder II draws a map and then superimposes the satellite's path. Real time tracking is made possible through a software clock, with screen updates occurring at each subsatellite point.

Two kinds of real time tracking are available. One uses a map of North America, and just as shown on the March, 1982, *73* cover, the states are outlined. The second option, a Mercator projection world map, is new. The global image makes the program useful to DX stations and allows state hams a glimpse of what the satellite is doing when it is out of range.

Both real time tracking maps work pretty much like the magazine version. The main difference seems to be the absence of range circles in the commercial program. My enthusiasm for Pathfinder's real time tracking is tempered by the opinion that during an actual satellite pass, an operator can't afford to spend time looking at a computer screen; however, there is still plenty of incentive to use the program before an operating session, acquainting yourself with the upcoming orbits. Finally, Pathfinder II's graphics are a great teaching tool and I enjoyed playing—plugging in different combinations of orbital parameters and then observing the results.

Hard copy of the map images is available if you have an Epson printer with the Graphtrax option. My printer didn't qualify, but I did manage to get a "screen dump" by using a Grappler interface board and NEC 8023 printer. The result, shown in Fig. 1, is missing several lines of text but is otherwise identical to the screen display.

The package's second module, called "Pathfinder Predict," provides orbital data that can serve as the base for Pathfinder II calculations and provide quick feedback about those orbits that will be most useful. Data can be calculated for all future orbits, all accessible orbits, or just each day's first orbit. Using an "exclusive" algorithm, the program generates the acquisition of signal time, loss of signal time, total time in range, maximum elevation, range at the closest approach, and the time when the closest approach occurs.

Pathfinder Predict offers seven different kinds of printouts, making a printer almost mandatory. Using Pathfinder Predict you'll be able to generate tables of data similar to those presented in *73*'s "Satellites" column. And you can go one step further by printing out detailed data for just those orbits that will be in range. Serious satellite users may even find Pathfinder Predict to be more helpful than the graphics-oriented Pathfinder II module.

My only complaints could almost be labeled nitpicking. Error-handling leaves room for improvement, there should be a default entry for your location, and the manual has occasional misspellings. But, as with any old friend, I tended to overlook the minor defects and so I was not disappointed by my surprise reunion. Written by hams for hams, Pathfinder II does all that Computer Applications says it will do, does it well, and does it for a reasonable price. Pathfinder II sells for $39.95 and is available from *Computer Applications, 3628 A Court, Oxnard CA 93033.* Reader Service number 478.

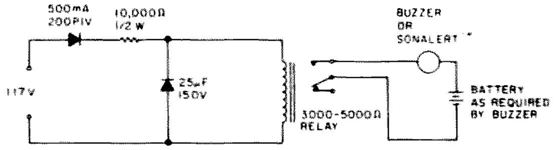
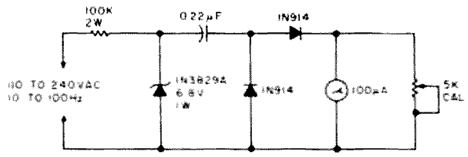
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

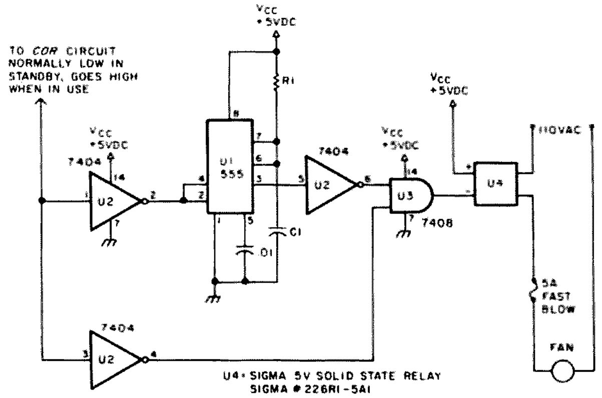
In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73 Magazine, Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



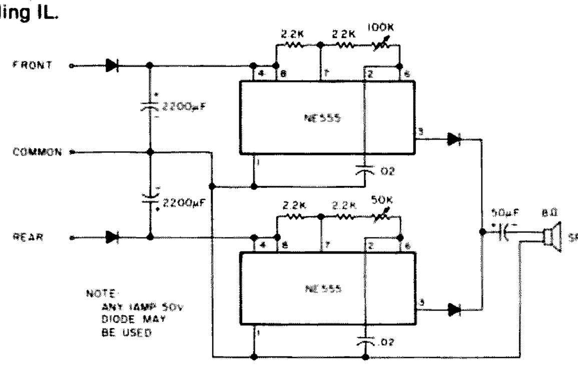
POWER-FAILURE ALARM: Don't get caught in the dark wondering what time it is. While power is on, the relay is held open, but when the power fails the buzzer-circuit contacts close. The relay can be a radio-control type with a pull-in of 3-5 mA.—Ed Schilling K5RSO, Fairfax VA.



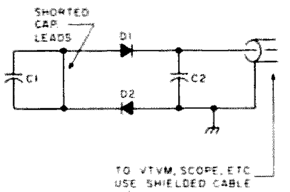
HANDY POWER-LINE FREQUENCY METER: A great piece of gear for Field Day, this meter will indicate the frequency from a power generator. Incoming sine waves are converted to square waves by the 100k resistor and the 6.8-V zener. The square wave is differentiated by the capacitor and the current is averaged by the diodes. The average current is almost exactly proportional to the frequency and can be read directly on a 100-mA meter. To calibrate, hook the circuit up to a 60-Hz power line and adjust the 5k pot to read 60 mA.—Joe Tracy K1LSP, Brookfield CT.



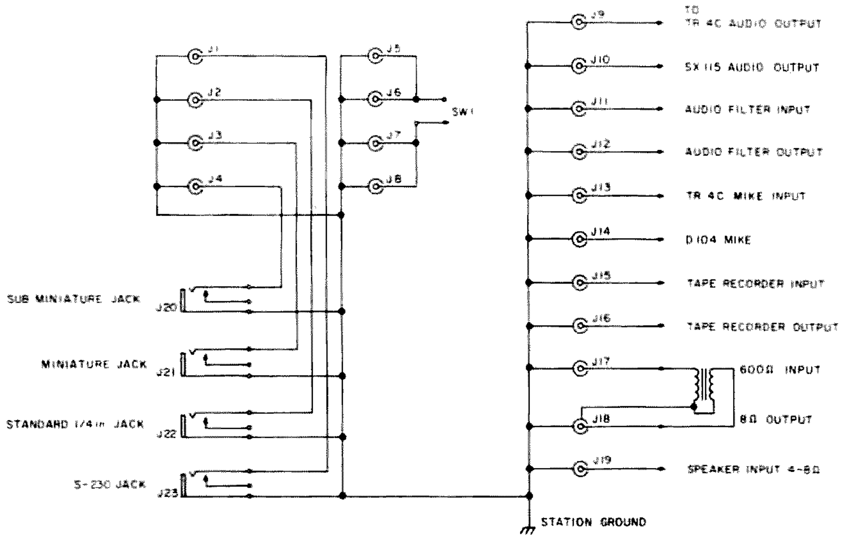
TIME-DELAY CIRCUIT FOR A REPEATER COOLING FAN: Keep your finals cool with this circuit which will start the fan when the system is in operation and leave it on for a short time after use. The values of R1 and C1 determine the time delay.—Richard Little K9EEH, Sterling IL.



ELECTRONIC DOOR BELL: Frequently the ding-dong of a door bell is unheard because you are in a remote part of the house. This electronic alert is much louder and requires no change in the original transformer or the push-button wiring. Most door-bell transformers are 16-24 V ac and when rectified and filtered, they provide sufficient dc to operate the NE555 oscillators at an adequate speaker volume. The two oscillators may be adjusted to distinguish between the front and back doors.—W. W. Davey W7CJB, Missoula MT.



LOW-LEVEL RF SNIFFER: This simple detector will provide indication of very low levels of rf, such as those on the outside of coax or inside enclosures. C1 is a disc capacitor of any value, C2 is from .001 to .005 uF, and D1 and D2 are 1N60 diodes or their equivalent. House the circuit in a plastic enclosure with only a portion of C1 protruding. The sensitivity of the probe is a function of the indicating device being used. For example, a high-impedance meter will show several volts in the presence of a low-level field.—Edwin Lawrence W8IGN, Seminole FL.



SIMPLE PATCH PANEL: This panel will provide all the necessary hookups between dissimilar equipment. The diagram shown is merely a prototype; the panel can be expanded with ease. SW1 provides for two or four multiple outputs. J1 through J19 are RCA-type phono jacks. J20 through J23 use jacks which fit your particular equipment needs.—Harry Longerich W4ANL, Fredericksburg TX.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

WORLD COMMUNICATIONS YEAR RTTY CONTEST

Contest Periods:
0000 to 0800 GMT June 11
1600 to 2400 GMT June 11
0800 to 1600 GMT June 12

Formerly the VK/ZL/Oceania RTTY DX Contest, the contest is organized and conducted by the Australian National Amateur Radio Teleprinter Society with trophies donated by the secretary of the ITU, Mr. Butler. Entry classes include single-operator, multi-operator, and SWL. Each station may be worked only once per band, but may be worked on another band for further multipliers.

EXCHANGE:

Serial number consisting of RST, zone number, and time in GMT.

SCORING:

As per CARTG Zone Chart, multiplied by the number of countries worked, multiplied by the number of continents worked (6 maximum). After the above calculations, world stations add 100 points for each VK/ZL station worked on 20 meters, 200 points for each on 15 meters, and 300 points for each on 10 meters. Countries count as per the ARRL list of countries, except that each VK, ZL, JA, VE, VO, and W/K district counts as a separate country. Contacts with one's own country count zero points for multipliers.

AWARDS:

Trophies to first-place single- and multi-operator entries on world basis donated by Mr. Butler of the ITU. Trophies to first-place single- and multi-operator entries in VK donated by ANARTS. Trophies will be presented by Mr. Butler at the IREE convention to be held in Sydney between September 5th and 19th. Certificates will be issued for second- and third-place entries on a world basis and for the winner in each country. A certificate of participation signed by Mr. Butler will be issued to all contestants.

ENTRIES:

Logs must show (in this order) date and time (GMT), callsign of station worked, serial number sent and received, points claimed. Logs of multi-operator stations must be signed by all operators, together with a list of their callsigns. Incomplete loggings are not eligible for scoring. Logs must be received by the Contest Committee by August 19th. Address all logs to: W. J. Storer VK2EG, 55 Prince Charles Road, French's Forest 2086, N.S.W., Australia.

Summary sheet must show callsign of station, name of operator(s) and address of same, bands used (a separate log is required for each band), the points claimed for each band, the number of VK/ZL stations worked, total points claimed, and signature(s).

The judges' decision regarding the placings in the contest will be final and no correspondence will be entered into regarding the same. The logs become the property of the Contest Committee on completion of checking.

SUMMER SMIRK PARTY CONTEST

Starts: 0000 GMT June 17
Ends: 2400 GMT June 19

The contest is sponsored by the Six-Meter International Radio Club (SMIRK). No crossband contacts, multi-operators, or partial contacts are allowed. Check logs or dupe sheets are not needed.

EXCHANGE:

SMIRK number and ARRL section, foreign state, province, prefecture, or country. Count ARRL sections in the 48 US states only; KH6 and KL7 count as countries. Washington DC counts as a section, as well. Canadians count as provinces; all others count as states, provinces, prefectures, or countries.

SCORING:

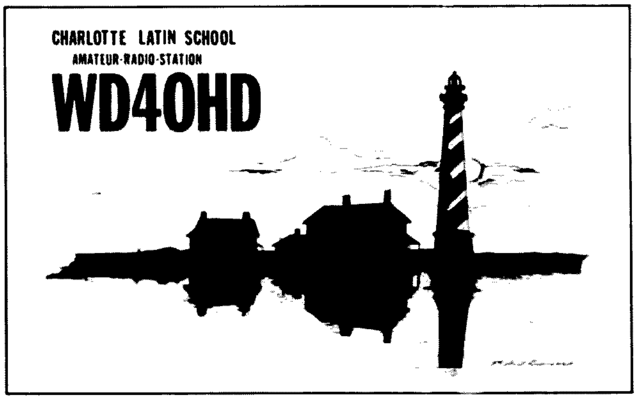
Count 2 points for each SMIRK contact, 1 point for each non-SMIRK QSO. Add QSO points and multiply by number of ARRL sections, foreign states, provinces, and countries worked for final score.

AWARDS:

Trophies for high-score SMIRK in two divisions: US/Canada and foreign. Certificates for high score in each ARRL section and foreign state, province, prefecture, or country.

ENTRIES:

Entries must be submitted on the fall, 1981, edition of the official SMIRK log. Single copies are available for an SASE and photocopies may be used. Send log requests and entries postmarked by July 11th to: Spencer F. Ritchie KC2TX/5, 5122 Sagamore, San Antonio TX 78242.



QSL OF THE MONTH

Who says kids aren't interested in ham radio anymore? This month's winning QSL comes from the Charlotte Latin School club station in Charlotte NC. The school is a private, coeducational institution located on a 92-acre campus on the south side of Charlotte. Bob Olson WD4OHD, director of the school's ham club, said that the card was designed by one of the students, and he added that the club is active and growing. And with all the new members, the book they requested for winning the contest was an obvious choice: *73's Novice License Study Guide*.

If you think your QSL is a winner, put it in an envelope with your choice of a book from 73's Radio Bookshop and send it to 73, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries which do not use an envelope or do not specify a book will not be considered.

NINE-LAND CW CONTEST

Starts: 1700 GMT June 18
Ends: 1700 GMT June 19

This is really an "everybody works everybody" contest sponsored by the Joliet Amateur Radio Society. The same station may be worked once per band. Operating categories include single operator (1 transmitter), multi-operator (1 transmitter), and multi-operator using portable field conditions with a maximun of two transmitters.

EXCHANGE:

Consecutive serial number beginning with 001 followed by state, province, or DX country.

FREQUENCIES:

1805 and 60 kHz up from lower edge of 80, 40, 20, 15, and 10 meters; Novices use 25 kHz up from lower edge of Novice bands.

SCORING:

Contacts with 9-land stations count 2 QSO points each; others are 1 point each. Multipliers are the number of states, Canadian provinces, and DX countries worked. Count a bonus multiplier for every 20 9-land stations worked.

AWARDS

Certificate to high score in each category in each state, province, and DX country.

ENTRIES:

Dupe sheets are required for over 200 contacts. Logs must be postmarked by July

23rd. Enclose a business-sized SASE for results. Send logs, dupe sheets, and summary sheet to: Paula Franke WB9TBU, PO Box 873, Beecher IL 60401.

STATIC SHEET

NEWSLETTER OF THE MONTH

Some club newsletters contain little more than the date and time of the next meeting, late dues notices, and a bimonthly request for more member participation in club events. But the *Static Sheet* stands out from that crowd like 75 wpm in the Novice band.

The *Static Sheet* is the monthly publication of the Des Moines Radio Amateurs Association, and it runs an average of 20 pages each issue. The newsletter, which is about the size of a playbill, is held together with a saddle binding rather than just stapled in one corner, which gives it a true magazine-like appearance. The front cover usually has artwork or photographs, and the masthead is striking against the white background.

But there is more good stuff inside the *Static Sheet*. "Honest John Says" brings the humor of a Don Rickles to the pages of the newsletter. With a sure aim, Honest John throws humorous barbs and one-liners at the members of the club. Other regular features include "DX in the 80s" and "The Last Word," where straight-shooting editor Ron Kinton WB0MBZ turns his thoughts loose.

The *Static Sheet* also has feature articles on local hams and offers the reader voluminous club news in its never-ending effort to keep the members active and informed.

Just as static is composed of many different frequencies mixing together, many voices comprise the *Static Sheet*, and editor Kinton deserves the credit for bringing it all together into a coherent whole.

To enter your club's newsletter in *73's* Newsletter of the Month Contest, send a copy to *73*, Pine Street, Peterborough NH 03458.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

I dedicate this column to all of you, the readers I love to hear from, who have made this column grow over the past six years. I enjoy your comments, suggestions, and questions and shall share some of them forthwith.

A short note from N4AN, whose signature is as illegible as mine, regarding the February, 1983, column and various types of encoded RTTY. He states, "There is some stuff on the air that *no one* will copy except the people it is intended for." I agree. But isn't it fun trying to decipher such undecipherables? At least, in a strange sort of way.

Regards to Bernard P. Ginsberg, M.D. KC6P (ex-WA3WNA), a physician in family practice and gynecology out in Santa Monica. Bernie was a familiar voice on the Baltimore Amateur Radio Club repeater when he lived here in the Baltimore area, and I'm sure he is just as noisy in Los Angeles. Bernie is working on interfacing his Sinclair ZX-81 (AKA Timex 1000) to RTTY. I keep asking, Bernie, but have heard nothing. Will keep the gang posted when I know something.

The 6800 crowd continues to be heard from. You know, I read in most of the computer magazines that the eight-bit processors are dead, especially the 6800. I don't know. Mine is still going strong and judging from the mailbag, so are many of yours. John H. Davison W0ZFN runs his 6800 in a Motorola D1 evaluation board. His homemade systrem runs fine, and he is trying to get his system up on RTTY. Hopefully, some of the stuff printed here will help.

T. Nick Hulbert KG5N of Lubbock, Texas, is another 6800 owner still with us. His SWTP 6800 is waiting for the conclusion of that RTTY program we talked about a while back. It may take a while, and it may be presented for more than one system at one time, but it will be here; just hang in there.

Ditto to Colonel B. J. Smith (USAF-Ret.) W5RYW. The colonel, who signs himself "B. J." (shades of M★A★S★H), is another SWTP 6800 owner trying to interface his computer to his amateur station.

Somewhat more adventurous is Harold B. Blethen WB1HBD. Harold is looking for a dedicated microprocessor to build into a RTTY system, using the James keyboard as an input device. Well, I reviewed the James keyboard in this column many months ago, and except for the fact that it cannot generate two of the ASCII control characters and that the CAPS LOCK key affects many of the symbol keys strangely, this is a good keyboard. In fact, I am typing this column on one, right now.

Another item mentioned here before, the Kilobaud Klassroom single-board computer, may well serve as the heart of your project. This small 6800-based computer is available from Star Kits, PO Box 209, Mt. Kisco NY 10549. Pete Stark K2OAW, the proprietor up there, produces quite a few items of interest for the 6800 crowd, several of which I have yet to see but would like to. Tell him "RTTY Loop" sent you! You're also going to need some kind of video display. My favorite is the GIMIX board, but there are several around these days. Look around, and good luck.

Interfacing computers with radios is always fun, and each camp has its advocates. Another 6800 user, Peter Bennett VE7CEI, passes along his favorite circuit. Peter uses this to interface a 60-mA loop to a TS-820 FSK input, and he also has a suggestion for a transistor-output switching to ground. Fig. 1 shows Peter's two ideas.

Rob Lawson WB4BSZ in Pensacola, Florida, mentions that he has a Color Computer (TRS-80C*) and has been trying to get it onto RTTY. One of Rob's hopes is to use the TRS-80 graphics on the air for some "creative RTTY." You know, this is one area about which little has been written, and now that ASCII is legal over the air, I expect more will show up. I can visualize an adventure-type game which would use back-and-forth transmissions to move through a game. This should be easier than a real-time game like Pac-Man™ or such.

John F. Deane KA1FL from Hanover, Massachusetts, is another Color Computer user. He casts his vote for chip-of-the-year for the 6809. His reasons for the 6809, housed in the CoCo system, include the opinions that the 6809 is a versatile chip, and that the CoCo is an inexpensive, "almost RFI-free" computer with a good keyboard. At least there are real keys! He mentions the built-in interfaces for the RS232C and SS-50 buses, and that the family can use it when the ham is not. Sounds like some convincing arguments for using this system. Along with some of the RTTY interfaces we have mentioned here over the past few months, I think this may well make a fine entry into computerized RTTY.

Another CoCo devotee is Joe Ryan WB5LLM of Florence, Mississippi, who passes along information on his RTTY setup. Joe indicates that his "low-cost" station includes a TRS-80C reading RTTY off an old CV-89A demodulator. This is a tube-type boat anchor of the same vintage as an old Northern unit I once had. He has copied all kinds of RTTY with this setup, using an optoisolator to connect the demodulator to the computer. Well, there's always a way.

Not to be left out, there are users of non-68xx systems who like to get their two cents in now and then. Charles W. Hoppesch KD4JG of Merritt Island, Florida, is one of them. He has been trying to get his TRS-80 Model III up on RTTY. Again, there are several interfaces available with different features for different money. Several have been discussed here in the past few months; drop their makers a line. I am sure that they will be able to provide literature to help you compare. Let me know how things work out.

Bob Workman WA4ZZN, Atlantic Beach, North Carolina, is trying to get onto RTTY with an old Teletype® Model 15 and a Northern Radio Convertor Type 152, Model 2.

* TRS-80C is a registered trademark of Tandy Corporation.

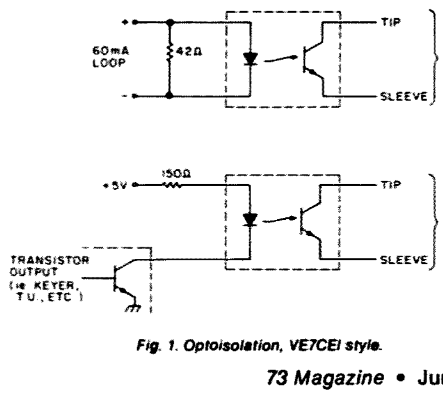

Fig. 1. Optoisolation, VE7CEI style.

This brings back memories of that same old Northern type 107 mentioned above. It was a boat anchor, but it copied RTTY "real good." Bob relates that the filters for mark and space are missing, and he wants to try to substitute for them. My presumption is that you will be able to use mark and space filters similar to the ones used in so many home-brew RTTY systems. For 170-Hz shift RTTY, it really does not matter what two frequencies you use as long as they are separated by 170 Hz. But just for the sake of compatibility, let's use the "standard" tone pair of 2125-Hz mark and 2295-Hz space.

All you need to do to put such a filter together is parallel a coil, typically an 88-mH toroid that can be purchased from many mail-order suppliers, and a capacitor of the appropriate value to resonate at the desired frequency. For 2125 Hz, this is nominally 0.068 uF, and for 2295 Hz, 0.056 uF *plus* a tad. These values are starting ones. Add capacitance a little at a time until the combination resonates at the desired frequency. Use the setup in Fig. 2 to view the moment desired.

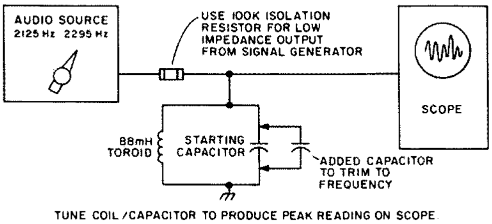

Fig. 2. Tuning a toroid filter.

RTTY Books

Back in the mid-1960s, when I got my first RTTY station on the air, I went to my mentor, Ted Fisher W3EOV, for guidance. After discussing the whys and wherefores of RTTY, Ted copied down a list of numbers and pressed them into my trembling hands. I don't remember how many of those numbers, frequencies in the HF spectrum, panned out, but that was the first list of non-ham RTTY frequencies I ever saw.

From that list, culled by one individual's listening, we have come quite a way: This month, the mail brought several new RTTY frequency books, from two sources we have mentioned before.

The first offering is from Oliver P. Ferrell, whose second edition *Guide to RTTY Frequencies* is being published by Gilfer Associates, Inc. This book, just short of 200 pages, is a storehouse of information about quite a variety of RTTY signals. It begins with a brief but accurate introduction to RTTY, with some general information about various forms of RTTY. There are some pointed remarks which the author terms "Putting Newscasts In Perspective" which I think are worth paraphrasing here.

The RTTY listener looking to latch onto the "hot" news wire can expect that less than ten percent of all RTTY newscasts will be in English and can be copied in North America. Stations transmitting RTTY are not bound by published frequency lists; they can—and do—change frequencies every few months, and newscasts are not sent continuously—that mark signal you tune across now may be sending what you were looking for fifteen minutes or fifteen hours ago.

After these explanations (either cream or fat depending on your point of view) comes a list of over 5000 signals, listed in frequency order. For each listing, information supplied included frequency in kHz, callsign if available, location if known, service (fixed, aeronautical, etc.), mode (shift, speed, orientation), power, and special remarks. Listings are included from 4 to 28 MHz and feature all kinds of transmissions, from press to embassy to weather to traffic.

Following the frequency list is a reverse list ordered by callsign. So, if you hear a call, you can look it up and get the same kind of information as if you looked up the frequency alone. Unfortunately, my review copy was missing one set of pages—the one that ended the frequency list and began the callsign list—so I cannot tell you whether or not the stations that have no call in the frequency list are represented in the callsign list, and if so, how. If I remember, and ever find out, I will let you all know.

A list of Z-codes follows the frequency lists. The Z-codes are the military equivalent of Q-signals and should be familiar to all of you who have ever checked into a MARS net. How well I remember the days of sending ZKE QRU, which roughly translates as "checking into the net (ZKE) with no traffic (QRU)." If you monitor military stations, this list can render what might seem like a meaningless string of three-letter codes into a meaningful string of statements.

After all these listings, an article is included called "Getting to Know Cyrillic." This is an overview of RTTY used by Soviet stations, which employ the Cyrillic alphabet of the Russian language. The basic information presented includes the second- and third-register Cyrillic systems. Unfortunately, I don't think there is enough there to really enable you to make much of what you will receive should you tune in such a station, but it makes for good reading.

Finally, a list of abbreviations used in the listings clarifies any remaining questions you might have about what the book says. All in all, this is a rather complete text. It sells for $9.95 and is available from Gilfer Associates, Inc., PO Box 239, 52 Park Avenue, Park Ridge NJ 07656.

In past columns, we have covered several of the publications from another source, Universal Electronics, Inc., and now we have two more which are described in this issue of *73* under "New Products." Be sure to check them out. See you next month in "RTTY Loop."

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

It is hard to believe the years which have passed since our initial announcement of the famous *73* Awards Portfolio. During this period, we've seen the program grow significantly to become one of the most sought-after challenges facing amateurs today.

Consisting of five domestic incentives and six DX achievement programs, the awards portfolio has captured the interest of almost everyone on the bands, whether a rag-chewer or a big-time contester.

In the paragraphs to follow, I am listing the awards individually. Read through the rules with caution. The requirements are not as easy as one might first imagine. We want our award recipients to realize they had to earn their recognition, and therefore have designed each award to be somewhat of a challenge. Here are the six DX awards.

WORK THE WORLD DX AWARD

To enhance the enjoyment of working DX, the editors of *73* take special pleasure in introducing the most complex and probably the most sought-after award in existence today—the green and black Work the World DX Award.

1. The WTW Award is available to licensed amateurs the world over.

2. To be valid, all contacts must be made on or after January 1, 1979. There are no band or mode restrictions, but applicants will be given recognition for single-band or -mode achievements upon their request. Only DX countries shown on the WTW DX Listing qualify.

3. The Work the World program consists of six continental awards (North American, South American, European, Oceanic, Asian, and African), each of which is a worthy accomplishment on its own. Once application has been made for all six, the ultimate award, the Worked the World DX Award, will be issued automatically without charge. The operator who earns WTW recognition has truly "worked the world."

4. Requirements for the individual continental awards: North American Award—work 13 North American countries; South American Award—work 12 South American countries; European Award—work 12 European countries; Oceanic Award—work 12 Oceanic countries; Asian Award—work 12 Asian countries; African Award—work 12 African countries.

5. To apply for any of these awards, prepare a list of claimed contacts for each continent, listing all callsigns in prefix order. Include date and time in GMT, and the band and mode of operation.

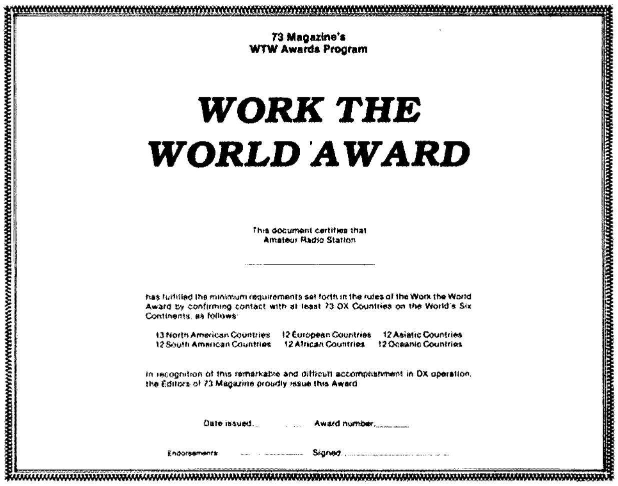
6. If you are submitting the sixth award application, please emphasize this fact to speed processing of your WTW Award.

7. Do not send QSL cards! Have your list(s) verified by two amateurs, a radio club secretary, or by a notary public.

8. Each continental award has an award fee of $4.00 or 20 IRCs.

DX COUNTRY CLUB AWARD

1. Sponsored by the editors of *73*, the *73* DX Country Club Award is available to licensed amateurs throughout the world.



73 Magazine's
WTW Awards Program

WORK THE WORLD AWARD

This document certifies that
Amateur Radio Station

has fulfilled the minimum requirements set forth in the rules of the Work the World Award by confirming contact with at least 73 DX Countries on the World's Six Continents, as follows:

13 North American Countries 12 European Countries 12 Asiatic Countries
12 South American Countries 12 African Countries 12 Oceanic Countries

In recognition of this remarkable and difficult accomplishment in DX operation, the Editors of 73 Magazine proudly issue this Award

DX COUNTRY CLUB

73 Awards Program

Number________________

This certifies that Amateur Radio Station

____

Has submitted evidence of confirmed contact via Amateur Radio with at least 73 DX Countries in one calendar year. This station is hereby recognized as a bona fide member of the 73 DX Country Club as a result of this operating achievement.

Signed:________________ Date issued:________________

Annual Endorsements

73 Magazine
Awards Program

Presented to Amateur Radio Station

____

In recognition of confirmed contact with the Capital Cities of 50 DX Countries

Award#________ Date:________

Endorsements:________________

Signed:________________

2. To be valid, all contacts claimed must be made in a single calendar year (January 1 through December 31), beginning January 1, 1979.

3. This red and maroon award is issued for all phone, all CW, and mixed modes. Should you wish to recognize a single-band or mixed-band accomplishment, merely state your request when submitting your application.

4. To qualify for any of the *73* DX Country Club Awards, a minimum of 73 DX countries must be worked and confirmed from the *73* WTW (Work the World) DX Listing which appears elsewhere in this column. Once again, all contacts must be made in the same calendar year for which application is made.

5. Annual endorsement stickers are available for each succeeding year in which application is made and which shows a minimum of 73 countries worked.

6. To apply, prepare a list of claimed contacts in prefix order. Include each station's callsign, date and time in GMT, mode, and band of operation.

7. Do not send QSL cards! Have your list of contacts verified by two amateurs, a local club secretary, or by a notary public.

8. Award fee is $4.00 or 20 IRCs for each award. Endorsements are granted for a fee of $2.00 or 10 IRCs.

9. For all *73* award applications: Enclose your verified list and award fee(s) to: Bill Gosney KE7C, *73* Awards Editor, 2665 North Busby Road, Oak Harbor, Whidbey Island WA 98277, USA.

SPECIALTY COMMUNICATIONS ACHIEVEMENT AWARD CLASS A

A significant number of amateurs throughout the world find their primary interest in the operation and development of specialty-type communications. It is the efforts of these many pioneers in their respective fields which have created many state-of-the-art improvements in technology today. The editors of *73* wish to recognize those amateurs who make positive steps toward expanding the use of their respective mode or type of amateur operation. As a result, in the paragraphs to follow, learn of our latest communications award, dedicated to "communicator specialists." Both Specialty Awards are green and black.

To be eligible for the award, all contacts must be made on or after January 1, 1980. In addition, only communications via SSTV, RTTY, EME, and/or OSCAR satellite will be recognized for this award. Contacts between stations on OSCAR or EME may be made using any authorized mode allowed in your country. Mixed-mode contacts, however, are NOT valid.

To qualify, applicants must work and confirm contact with each of the 50 US states. There are no band requirements, but specific band accomplishments will be recognized if requested at the time of application.

To apply, applicant must prepare a list of claimed contacts in alphabetical order by state. Include the date and time in GMT, the band and mode of operation, and a signed declaration of the type of equipment and antenna system utilized.

Do not send QSL cards! Have your list verified by two amateurs, a local radio club, or a notary public. Enclose with your application a $4.00 award fee or 20 IRCs.

SPECIALTY COMMUNICATIONS ACHIEVEMENT AWARD CLASS A-1

1. Sponsored by the editors of *73*, this award is dedicated to amateurs worldwide who take pride in active participation in the field of specialty communications.

2. To be eligible for this award, some very rigid requirements must be met. All contacts must be made on or after January 1, 1980. Only communications via SSTV, RTTY, EME (Earth-moon-Earth), and/or OSCAR will be recognized for award credit. Contacts between stations on OSCAR and EME may be made using any mode authorized in your country. Applicants must be cautioned, however, that mixed-mode contacts are not valid.

3. To qualify, applicants must work a minimum of 10 DX countries from the WTW DX Listing. Special recognition will be made for those exceeding the 10-country minimum.

4. To apply, the applicant must prepare a list of claimed contacts in callsign prefix order. Include the date and time in GMT, the band and mode of operation, and a signed declaration as to the type of equipment and antenna system utilized to make your contacts.

5. Do not send QSL cards! Have your list verified by two amateurs, a local club secretary, or a notary public.

6. The award fee is $4.00 or 20 IRCs.

DX CAPITALS OF THE WORLD AWARD

1. Sponsored by the editors of *73*, the blue and black DX Capitals of the World Award is made available to licensed amateurs the world over.

2. To be valid, all claimed contacts must be made on or after January 1, 1979. There are no band or mode restrictions, but special recognition will be given for single-band or -mode accomplishments if requested in the application.

3. To qualify, applicants must work and

DX Decade Award

Whereas: Continued activity on all amateur bands is vital to the preservation of those bands for amateur use; and

Whereas: It is particularly desirable to encourage utilization of the 10 Meter Band; and

Whereas: The applicant has demonstrated the ability to communicate on the 10 Meter Band using channelized AM equipment;

73 Magazine hereby presents this award to station

____

in recognition of communication with at least 10 foreign countries.

Date:________________ signed:________________

Wayne Green

Certificate #________________

confirm 50 different capital cities of the world. Only capitals of those countries which appear on the WTW DX Listing qualify. Should a country be contacted and its capital city not commnly known, you may list it on your application and the awards editor reserves the right to make a final determination as to its acceptance for award credit.

4. To apply, make a list of contacts made in prefix order. Indicate the station callsign, date and time in GMT, band and mode of operation, name of the capital city, and the DX country.

5. Do not send QSL cards! Have your list of contacts verified by two amateurs, a radio club secretary, or a notary public. The award fee is $4.00 or 20 IRCs.

TEN-METER DX DECADE AWARD

1. Sponsored by the editors of *73*, the black-on-blue Ten-Meter DX Decade Award is available to licensed amateurs worldwide.

2. All contacts must be made on the 10-meter band using only channelized converted Citizen-Band equipment or similar-type commercial units operating a maximum of 15 Watts PEP output. External amplifiers may not be used.

3. To be eligible for this award, all contacts must be made on or after October 1, 1978. Contacts may be claimed for all AM, SSB, CW, or FM. Mixed-mode accomplishments are not valid for this award.

4. To qualify, the applicant must work and confirm at least ten DX countries from the WTW (Work the World) Listing. Endorsements will be given for 25, 50, 75, and 100 countries confirmed.

5. To apply, make a list of contacts claimed, giving the callsign of each station worked in prefix order. Include the date and time in GMT, band, mode, and a brief description of the equipment used in making each contact. Special recognition will be given for QRP mobile achievements.

6. Do not send QSL cards! Have your list of contacts verified by two amateurs, a local radio club secretary, or by a notary public. The award fee is $4.00 or 20 IRCs.

******

Now here are the five domestic awards, also being sought after by award seekers the world over. These awards were not meant to be an overnight venture nor were they designed to duplicate any in existence today. Each offers its own degree of difficulty and creates a sense of accomplishment in those who are happy recipients.

WORKED ALL USA AWARD

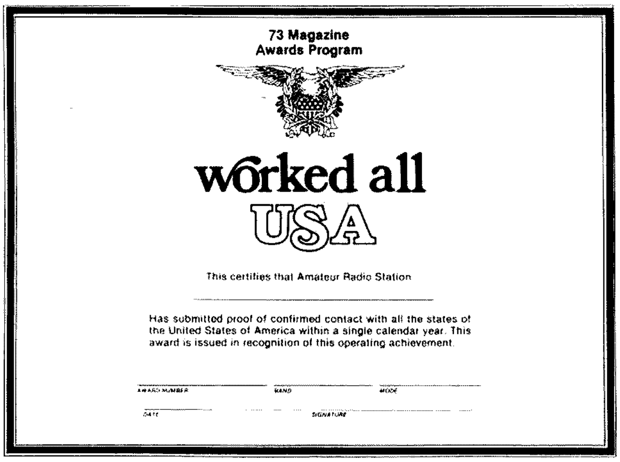
Sponsored by the editors of *73*, the black and maroon Worked All USA Award is available to licensed amateurs throughout the world. To be valid, all contacts must be made on or after January 1, 1979. There are no band or mode restrictions, but single-band and single-mode accomplishments will be recognized.

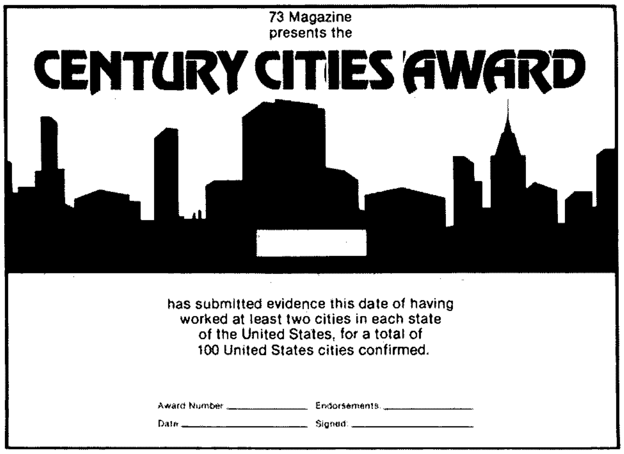
If you're looking for an award with challenge, this definitely is one. To qualify, applicants must work each of the 50 US states within the same calendar year (January 1 through December 31). Annual endorsements will be awarded applicants who can verify their claim.

To apply, prepare a list of claimed contacts in alphabetical order by state, beginning with Alabama. List the state, the callsign of the station worked, the date and time in GMT, and the band and mode of operation.

Do not send QSL cards! Have your list of contacts verified by two amateurs, a local radio club secretary, or by a notary public.

The fee for the basic award is $4.00 or 20 IRCs; endorsements are $2.00 or 10 IRCs.





The Worked All USA Award, with its 12-month limitation, separates the men from the boys. To date, only a few have mastered the 80-meter band, while 10, 15, and 20 have been more popular. Only a few aplicants have mastered all states on 6 meters, and 160 meters has been conquered only once. Does your station have what it takes to Work All USA in a calendar year?

CENTURY CITIES AWARD

Designed as a Dual-Worked-All-USA effort, the editors present this maroon and black Century Cities Award to the most demanding of amateur operators. The applicant who applies for this achievement realizes he has accomplished what is probably the greatest feat available in award programs today.

As with all *73*-sponsored awards (with the exception of the ten-meter incentives), all contacts must be made on or after January 1, 1979, to be valid.

To qualify, the applicant must work and confirm a minimum of two cities or towns in each of the fifty US states, for a total of 100.

To apply, prepare a list of claimed contacts in alphabetical order, by state. As shown below, include the full callsign of the station worked, the date, the band, and the city. Beginning with Alabama, your list will look something like the following: Alabama—W4ZZZ, March 31, 1979, 14 MHz. Decatur; N4XXY, February 1, 1979, 21 MHz. Mobile; Alaska—KL7AB, January 22, 1979, 7 MHz, Anchorage, May 19, 28 MHz, Fairbanks; and so on.

Do not send QSL cards! Have your list of claimed contacts verified by two amateurs, a radio club secretary, or by a notary public. Enclose this list along with your award fee of $4.00 or 20 IRCs.

TEN-METER 10-40 AWARD

What would an awards program be like without a QRP incentive? With 10 meters at an all-time high, the editors of *73* take pride in announcing the Ten-Meter 10-40 Award. Printed in black on blue, and designed specifically for owners of converted Citizens-Band equipment, the 10-40 Award is probably the roughest worked-all-states award program in existence. Ask those who have tried numerous times and failed!

Available to licensed amateurs the world over, the award offers a challenge second to none. To be valid, all contacts must be made on the ten-meter band using only "channelized" Citizens-Band equipment or similar commercial units. Power is limited to 15 Watts PEP output. External amplifiers are prohibited.

All contacts must be made on or after October 1, 1978, on SM, SSB, CW, or FM modes. Mixed-mode contacts NOT valid.

To qualify for this award, the applicant must work and confirm at least forty of the 50 US states. (An endorsement will be issued if all 50 states are worked.)

To apply, make a list of contacts in alphabetical order by US state beginning with Alabama. Include the call of the station worked, the date and time in GMT, the band and mode of operation, and a brief description of the equipment and antenna system utilized.

Do not send QSL cards! Have your list verified by two amateurs, a radio club secretary, or by a notary public. The award fee is $4.00 or 20 IRCs.

THE Q-5 AWARD OF EXCELLENCE

If you frequent the American Novice bands, you will be pleased to hear of an exclusive award for these bands. Sponsored by the editors of *73*, the black and maroon Q-5 Award of Excellence is available to amateurs worldwide who meet the requirements.

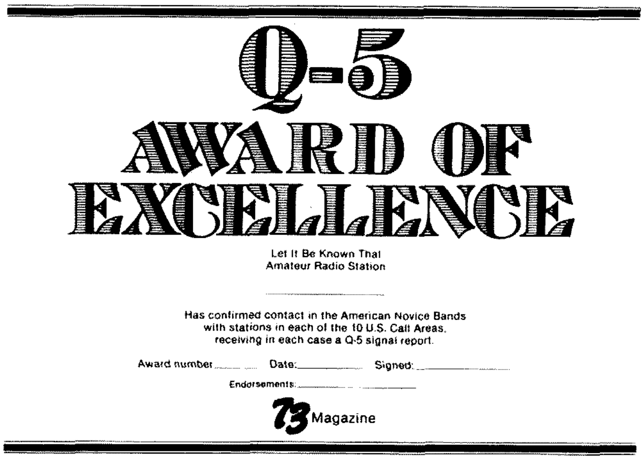
To be valid, all contacts must be made on or after January 1, 1979. All contacts must be made operating the CW mode on those frequencies assigned the American Novice. Applicants are cautioned that power limitations are 250 Watts input. There are no band restrictions, but applicants may request special band endorsement on the award if the request is made at the time of application.

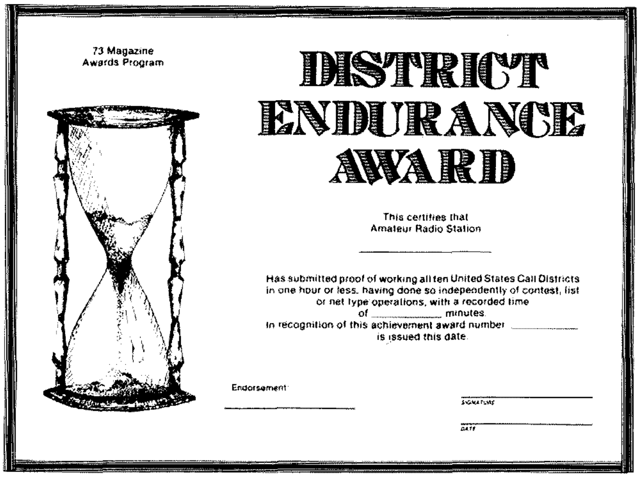
To qualify, applicants must work all ten US call districts and receive no less than a Q-5 report. A valid RST might be 559, 539, 579, etc., while an RST of 449, 349, or 479 would not quaify.

This award is not meant to be an overnight accomplishment. Stations meeting the challenge of these requirements will be proud to display this unique award depicting the excellence and superiority of the station's transmitted signal.

To apply, prepare a list of claimed contacts, logging each contact in order of the US call district. Include the station callsign, date and time in GMT, the frequency utilized, and, most important, the RST as noted on your confirmation card. Also required is a brief description of the station equipment and antenna system utilized to complete this award.

Do not send QSL cards! Have your list verified by two amateurs, a local radio club





secretary, or a notary public. Enclose with your application the fee of $4.00 or 20 IRCs.

DISTRICT ENDURANCE AWARD

If any of you feel our awards are too soft for you, take a hard look at our next award! This one, in black and maroon, was designed to appear fairly simple at first glance, but it will drive you up the wall with frustration as it is pursued. It is known as the District Endurance Award. You'll need to find yourself an accurate timepiece, as you'll have exactly 60 minutes to work all 10 US call districts! Simple, huh? Best time so far—8 minutes!

Sponsored by the *73* editors, the District Endurance Award is offered to licensed amateurs throughout the world. To be valid, all contacts must be made on or after January 1, 1979. There will be no band or mode restrictions, but if you are fortunate enough to work these requirements on a single band, we will be happy to recognize this feat when processing your award.

One of the most important rules applicable to this award is that all contacts must be made independent of nets or any net-type operation and must not be made while any contest is under way.

To qualify, applicants must work all ten US call districts in one hour or less. The time will commence the moment the first contact is established and end with the time logged for the last district required.

To apply, applicants must prepare a signed declaration that all contacts were independent of net or contest operation. Applications must include a list of stations worked in callsign order by district, the date and time worked in GMT, the band and mode of operation, and the state.

Do not send QSL cards! Have your list of contacts verified by two amateurs, a local radio club secretary, or by a notary public. Accompanying your application should be a $4.00 award fee or 20 IRCs.

*****

For applicants for the awards offered by *73*: I would like to give you some insight on how we process the paperwork. Upon receipt of an application, each award requirement is carefully scrutinized to see that the applicant has met each one to the letter. If approved, an award work sheet is prepared. The original copy of this and applicable award fee is mailed to Peterborough NH for the *73* art department to process. It is there that your award is given a personal touch and later mailed to your door. A copy of the award work sheet is mailed to the applicant to acknowledge receipt of the application. (Should the applicant feel it necessary to follow up, he or she should write a letter to the Assistant Publisher, *73*, Peterborough NH 03458. Writing directly to 73 headquarters will speed things up since the awards editor does not retain your paperwork once the request for issuance is mailed.)

We hope you enjoy the challenges of the *73* Awards Program and will share its rules with your amateur friends. While we hope you all will pursue the objectives these awards have to offer, we also hope you will send any information you might have on other award programs which have never appeared between the covers of this magazine. Looking through my files, I see where we have gone many, many months without duplicating information on a single award. Our files are getting bare, however, and it is the input of readers that keeps the image of this column original and creative. If your club has an award it sponsors, why not share it with our thousands of readers?

OHIO WINE WEEK

The Wireless Institute of Northern Ohio (WINO) will be on the air with a special-events station to commemorate Ohio Wine Week on Saturday, June 11, and again on Sunday, June 12. On Saturday evening we will be operating between 7 and 11 pm EDST (2300Z May 10 to 0300 May 11), on 3900 MHz and 7235 MHz. On Sunday afternoon we will be on between 11 am and 4 pm EDST (1500Z to 2000Z) on 7235 MHz and 21360 MHz. The station will be located at an actual winery in Madison, Ohio, using the call KØ8O, and a special QSL certificate will be available from: Scott Farnham KØ8O, 7126 Andover Drive, Mentor OH 44060, for a legal-sized SASE and an additional 40¢ (in postage or coin).

NAS MEMPHIS ARMED FORCES DAY

In recognition of the 34th annual Armed Forces Day celebration, amateur radio station W4ODR, located aboard Naval Air Station Memphis, Millington TN, will be operating on Saturday, May 21, from 1400Z to 2200Z. Plans call for operation on 7.230 (± 10 kHz), 14.280 (± 10 kHz), and 21.370 (± 10 kHz). The CW frequency will be 21.145. 146.52 will be the 2m frequency. It is hoped that operation will be continuous on all bands, but check all frequencies to be sure. Special certificates and QSL cards will be available to those who work W4ODR. QSL to amateur radio station W4ODR, PO Box 54278, Millington TN 38054.

MICHIGAN TORNADOES

The Macomb Emergency Communication Association will operate special-event station KA8KTV in commemoration of Michigan tornado season from 1300Z June 11, till 2100Z June 12. They will be on 20-meter RTTY (14.080-14.090), on 2-meter FM (146.07/.67), and on the upper General-class phone portion of 15, 40, and 80 meters as propagation allows. QSL with a certificate-sized addressed envelope to: KA8KTV, Box 291, Utica MI 48087. No return postage needed.

WORK THE BETHLEHEMS

W1FHP and the Hen House Gang will operate on 10, 15, and 40 meters from Bethlehem, Connecticut, The Christmas Town, Field-Day weekend, June 25 and 26, 1983. They also will operate July 9 from Bethlehem, New York and July 16 from Bethlehem, Pennsylvania. Awards will be available for working four Bethlehems from around the world. Send log information and a 20¢ stamp to Robert O'Neil W1FHP, Hard Hill Road, Bethlehem CT 06751.

NATIONAL HOLLERIN' CONTEST

Cape Fear ARS, Spivey's Corner, North Carolina, will operate WB4YZF from 1300-2100Z, June 18, from the 15th Annual National Hollerin' Contest. Frequency—phone, 7.235. Certificate available. For details, contact: Lee Brown N4DTB, 462 Shoreline Drive, Fayetteville NC 28301.

JAMBOREE IN THE HILLS

Special-event station W8QZ will be on the air during the Jamboree in the Hills on July 15-17, 1983. Operators from the Northern Panhandle Radio Club of Wheeling, West Virginia, will be on 7.280 and 14.280, ± 5 kHz, and a special QSL certificate will be offered to all stations worked. To receive the certificate, send an SASE to: Joe McCready WB8CTC, 111 Chase Ave., Bridgeport OH 43912. The event is being sponsored by broadcast station WWVA of Wheeling WV.

LETTERS

NERVES

I enjoyed your editorial in the March, 1983, issue of *73*. I had difficulty with code because of a nerve condition, not a memory problem. As a result, I was excluded from ham radio. I have been a microwave technician for 30 years and am a 1963 graduate of RCA Institutes, NYC. I always resented being excluded from a wonderful hobby because of a stupid rule. I wish there were more understanding people like you in the field.

Thomas Costigan
East Setauket NY

One is enough.—Wayne.

RETURN TO THE FOLD

Back in 1942, as a marine radio operator in the Navy Department, I operated CW circuits at speeds in excess of 50 wpm. On one occasion, I was timed over a three-minute period at 64 wpm, with a total of four mistakes. At the close of WWII, I lost all interest in radio and did not regain it until a group of CBers asked me to teach them the code. Now they all have their ham tickets, and I am a 62-year-old Novice, having received my license in January, 1980. I thoroughly enjoy the Novice bands because I can always find some poor struggling soul to lend a hand to in learning how to communicate. Because of this I will not upgrade my license until I join the ranks of the annuitants. Even then I will look for that Novice needing my assistance. I relate this to you in order to set the stage for what is really on my mind. Wayne, I am with you 100% on the no-code license. I totally disagree with the ARRL in their approach to this, and since they refuse to print anything but the silliest of objections to the code, I decided to let my membership die with the February, 1983, issue of *QST*. Lo and behold, on page 65, there with his bare face hanging out was W2NSD/1! Are they beginning to see the light, Wayne? Or did you and Carl sneak that one in one them? By golly, I may renew my membership if that keeps up!

Bill Haddad WD0HXH
Whiting IN

Surprised me, too.—Wayne.

SOGGY VIDEO

During the recent storms, two pieces of electronic equipment went into the "Mighty Blue Pacific," and both were saved. The first was my Icom IC-2AT hand-held. It slipped off my belt and was inundated with salt water before I could retrieve it. The key to saving it and a $5,000 Sony BVU-110 broadcast video recorder that got caught by a misguided wave the next day was to get it, while still wet, into a deionized water ultrasonic cleaner. In the case of the BVU-110, the machine was dissassembled and pressure cleaned, after which it was dried at 130 degrees for 36 hours. I then replaced all rubber, including belts, drives, etc. It has been in service for a month with no problems.

The HT was handled in a similar way, washing out all corrosive salt water before the salt began to dry and start its corrosive process. After 36 hours of drying, the transmitter and tone pad functioned properly, but the receiver would only emit toilet noises. After a quick consultation on the phone with Icom America, it was decided to send the unit for repair via the dealer it was purchased from. I dropped the unit at Ham Radio Outlet/Van Nuys on the Tuesday following the incident and had it back within 7 days, operating to perfection and at a very reasonable price. The sevice rendered by both HRO and Icom deserves acclaim. It's rare in this day and age to be satisfied the first time out. So, with thanks to the folks at HRO and to Mr. Tom Snelling at Icom, this letter is made possible.

Bill Pasternak WA6ITF
Saugus CA

DEATH THROES

I've been going to a local ham club's meetings for two months now. Unfortunately, the ham club does not. And then, guess what? Well, first they can't get quorums. Without quorums, there are no elections, nor can there be a vote on new membership applications (like mine). Second, without member attendance, there are no project proposals or programs. Then there are the somewhat outspoken, non-attending former members (including charter members) who apparently say, "The club is dead and the officers should stop keeping it artificially alive," or something to that effect, as reported by the club paper (the editor does a super job).

Well, I'm afraid that the club is about to die and the few attending members (mostly officers) are discussing solvency (ironically, they need a quorum to do so). Whether or not the club will formally dissolve is speculation, because one officer has pseudo-formally resigned (again, need a quorum). And I cannot hold it against him for doing so.

I wonder if nobody attends meetings for fear of being elected to office, or is it because nothing happens (except gab) when they do go? After all, it seems rather ludicrous to have a formal meeting to just gab when you can do it at your rig.

Perhaps the elimination of about 75 percent of the formalities, like the need for officers or structured meetings or running a treasury, would improve the situation. So that way, if the group does want to do something, they can "pass the hat" to finance it. Then, if nobody wants to do anything (or very many), nothing is lost and "members" could have a gab session without being put in an office position (the horrible dread).

Oh well, it looks like my two ventures to the meetings will be a loss. I'll just bet there are many, many "clubs" in the very same sinking boat.

Duane Grotophorst KA9HKL
Sauk City WI

Duane, you're right. Clubs should be for fun, with virtually no business meetings. There should be classes on code, theory, talks about DX, repeaters, show and tell of RTTY, slow scan, computers, packet radio, discussions of the articles in the latest magazines, club participation in contests such as Field Day, DX contests, sweepstakes contests, and so on. Get rid of the turkeys who try to conduct business meetings and replace 'em with a hot-to-trot program chairman. Bring in active local hams to talk, manufacturers, dealers, have QSL card showings, home-built gear shows, flea markets, auctions, and get some action going there.—Wayne.

OOPS

This letter is in response to one I wrote which you published in your magazine in March, 1983.

In the previous letter, I mentioned two operators who were on CB, supposedly running ham gear. Since this letter has been published, I have received many comments about it.

First, let me state that I never should have written about it or at least should never have mentioned the club calls I thought they were using. I admit that I should not have written the names they were using, although when I was a CB operator (not always legal), it was almost always common practice to say you were

somewhere other than where you were and be called by something other than your own call.

Secondly, I never meant to give the impression that the Mercury Sideband Club members were all illegal operators with no brains.

It seems as if I really struck a wrong note here in the area and I apologize for all the mess.

I still feel, however, that if there are any amateur radio operators who are in the club and are operating illegally, they should reconsider their actions. It would seem that their ham licenses are really of no importance to them if they don't.

Wayne, it seems that you and I are two of a kind, always out of step with everyone else. Guess that makes America what it is—a place where you can disagree and still be free.

So, in closing, once again I state my apologies to the many good operators in this area who are members of the Mercury Sideband Club and wish for them continued success in furthering the improvement of CB radio.

Wayne, thanks again for your help.

Jerry Rogers KA8PTL
Monroe OH

Oh, baloney. I'll bet you were right the first time. Don't be so wishy-washy.—Wayne.

GUAM GROANS

In your January issue, you said, "DX is out there, where are you?" I would like to reply to part of that question from a possible DX point of view. I am over 7,000 miles from Kansas so I think I may be a DX station, but I have two problems. I work the Novice bands on 10 and 15 because I am a Technician and the nearest FCC examination point is 3,000 miles from here. The FCC sure doesn't come to us. I also work CW because I sincerely enjoy it.

That was problem number one. Problem number two is that I have a California "6" call because of my address. Wayne, I have answered CQ DX calls from all over the states, most with a 559 or better signal, and I often get, "I was calling DX; do you know what DX is?" I was even interrupted once while in QSO with a VK station by a K6 that wanted to make a DX contact with VK-land. That's all fine, and no problem, but when I went back to him with N6HSC/KH2, he said he wasn't interested in California. My standard reply is "73 from Guam" and then I ignore the commotion as they realize they blew it.

I suppose most Novices have drawers full of KH2/KG6 QSLs, but I sure don't have any quanity of their cards. I can work JAs and VKs anytime I want and, when the bands open, cause a pileup in Europe, but I can't get a KA to come back to me unless I pretend I'm in California and drop the /KH2. At least one KA6/DU2 shares my frustration. I would like to get Guam in a few more Novice logs. I average one contact in the states for each five hours of operation and that's ridiculous. I know you guys can hear me when the band is open. Please inform your readers that there are stateside calls all over the world operating portable something or other, and most would welcome a call. Almost 100 percent of my QSLs say "Thanks for my first Guam contact."

Wayne, we're out here trying, but probably not for much longer. I, for one, will go back to my JAs and VKs and say to hell with the stateside guys.

Preston Allen N6HSC/KH2
Agana, Guam

Those DX snots don't know how to fill out a QSL anyway.—Wayne.

FREE TAPE

The Wichita Amateur Radio Club invited Dick Abraham, corporate engineer for Multimedia Cablevision, the Wichita cable franchise, to speak before our group at our December 1, 1982, meeting. Dick did a lot of homework and made an excellent presentation.

We recorded his presentation and will be happy to make a copy available to anyone who would like a copy. To obtain one, mail a C-90 cassette and an SASE to me. We have bulk duplicating equipment and will be able to get copies out immediately. Any request without a C-90, SASE, or both will be thrown away.

I don't believe Dick's presentation has any real "news" value; however, it would be helpful to those who are having trouble with their local cable operators and especially helpful to those whose communities will soon be building cable systems.

The Wichita cable system is not tight. There are leaks on 145.25 MHz all over town. But Dick has promised to fix those that exist, at least to the letter of the law and better than that if he can. All we have to do is notify him of their existence. Amateurs in Wichita don't like having to coexist with cable but realize they have a much better situation than most. At least our local cable operator has made helpful overtures.

Dick Houser WDØENU
PO Box 1402
Wichita KS 67201

SCHOLARSHIPS

The Atlanta Radio Club announces that three cash ($500) competitive scholarships will be awarded to graduating high school seniors who will enter an accredited college or university in the fall of 1983. Recipients must be duly licensed amateur radio operators at the time of application. The scholarships are awarded on the basis of both scholastic attainment and outstanding efforts as amateur radio operators.

This is the fifth consecutive year in which the Atlanta Radio Club has been able to award scholarships to deserving amateurs.

For additional information and application forms, write to: Phil Latta W4GTS, Secretary, Atlanta Radio Club Scholarship Committee, 259 Weatherstone Parkway, Marietta GA 30067.

Completed applications along with the required high school transcripts must be postmarked not later than July 31, 1983.

Atlanta Radio Club, Inc.
Atlanta GA

BEACON

On January 5, 1983, I put KA1YE/B on the air from Oakdale CT. The beacon is running 2 Watts output to a vertical antenna on 28.284 MHz. The beacon operates 24 hours a day and provides a consistent signal source for checking out 10-meter propagation. At this time, the ID is on FSK, but it will changed to an all-CW format soon. I am also putting beacons on 6 and 2 meters, hopefully by May 1, 1983.

I would like to receive some reception reports from US and Canadian amateurs, especially this summer during the sporadic-E (short-skip) season. Any unusual propagation noted would also be of interest. Reception reports can be sent to my 1983 *Callbook* address, or foreign reports can be sent to the W1-land bureau, c/o my call.

So far, the only reports I have received from US amateurs have come after I requested them to listen specifically for the beacon. Many amateurs, even those who are consistently on 10 meters, do not seem to be aware of the extensive DX beacon system on from 28.200 to 28.300 MHz. In the last 2 months, I have logged over 30 DX countries, in all continents except Asia, on the beacons. Many times I have heard the beacons S7-9, only to hear some stateside station say, "Gee, 10 meters was great when it was open." Give a listen down there. Ten meters is open much more than most hams realize. Let's use the band. See all of you on ten.

W. Keith Hibbert KA1YE
Niantic CT

RAVE REVIEW

I want to commend you and your staff for the excellent product reviews. I find them superior to those of the other ham magazines.

Frank Vogel WB5PMU
Cherokee IA

You are very perceptive.—Wayne.

FCC

NO-CODE COMMENT EXTENSION

The FCC has extended the deadline for comments on the no-code license by 60 days, giving hams until June 28 to file their suggestions.

In February, the Commission released a Notice of Proposed Rulemaking setting forth two alternatives for a theory-only amateur license which would offer VHF privileges similar to those for the present Technician license. When the notice was released, the comment deadline was dated April 29, with reply comments due one month later.

The extension came in response to a March request by the ARRL which argued that the League's members needed more time to discuss the issue and that members' responses would not be considered until the April 21 and 22 Board of Directors meetings.

In its statement, the FCC said, "We concur . . . that a no-code amateur radio license is a core issue for the amateur community. Since we want the input from amateur radio operators to reflect thorough and dispassionate consideration, we will grant the requested extension of time."

HAM HELP

Wanted: the manual, or a copy of it, for the Clegg Thor RF 6-meter rig and the Heath GR-81. I will pay postage and copying costs.

CORRECTIONS

Although the tunable Pocket Weatheradio used in "Put 2 Meters in Your Shirt Pocket" (March, 1983, p. 46) is no longer available from Radio Shack, the crystal-controlled Weatheradio (RS no. 12-151) will work even better. It draws only 10 mA, needs no squelch, and modification is simple.

Remove the 16-MHz weather crystal and replace it with a 2-meter transmit crystal approximately 455 kHz above or below the intended receive frequency. If a standard transmit frequency does not fall exactly 455 kHz above or below the intended receive frequency, the i-f detector transformers can be shifted at least 50 kHz and there is also an internal trimmer capacitor and variable inductor to shift the crystal frequency. The two-meter crystal can be either 12- or 16-MHz fundamental. The crystal I use is from an Icom 22A and has an 18-MHz fundamental. Add a 5-pF capacitor across the 2 rf amplifier inductors and spread or compress it to achieve maximum sensitivity.

Lester Kolb K3PJG
Lebanon OR

An error appeared in the schematic for "QRM Eliminator for Computer CW," which was part of the Circuits feature on page 105 of the April, 1983, issue. The junction of C2 and C3 on U1 should be grounded.

Avery L. Jenkins WB8JLG
73 Staff

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

ARRL. What would happen to a *Relay* League based upon Morse-code-trained operators if automation was permitted to set in and allow messages to be sent without these operators? The whole concept struck at the heart of the League. Well, here we are 33 years later and the ARRL has every reason to be very proud of itself. They have managed to fight off modern communications techniques for over three decades, keeping us in the medieval days.

Is it any wonder that people working in the communications field look on hams as hangers-on from the long-gone past of radio? We've been left so far behind current technology that it is going to take us years to catch up. Our communications systems are so irrelevant and wasteful of people that no one really takes us very seriously. Oh, they would like to get the radio spectrum we've managed to hold onto over the years. Every shortwave channel is worth many millions of dollars when used for an efficient communications system.

So please don't do the old Captain Queeg bit and try to get anyone to seriously think that hams are ever going to use Morse code for anything but a monument to our resistance to progress and our insistence on wasting billions of dollars in radio channels for little more than entertainment. I suppose that we do agree that it is entertaining to sweat out a CW contact with someone a few hundred miles away, managing to get his name, location, rig model, type of antenna, and a brief on the weather as the reward for fifteen minutes or so invested. It must be fun or we wouldn't see so many hams devoting the declining years of their lives to this.

I'll agree that using the good old Morse code can be fun, but it isn't anything I can take seriously as a means of communications, and it hasn't been for years. I don't think anything can happen that will put us back into the spark days. Heck, it's getting difficult to come up with an old Ford coil these days. Old-timers will fondly remember those little wooden boxes we used to hook to number 6 dry cells and generate tens of thousands of volts. They came from the good old Model T cars and were everywhere... for a while. You could hear 'em for a mile on *any* radio.

It may be time for us to stop looking at the past and take a more serious look around at where the commercial firms are with their communications in the 1980s and see if we can at least catch up. The time was when amateur radio waa ahead of the commercials, not lagging them by 50 years. We have plenty of ICs to work with and the support of a growing number of ham-oriented firms to help us get going with high-speed digital communications.

We may want to continue our traffic nets as they are... much like keeping antique cars running and preserving Williamsburg or New Hampshire's Strawbery Banke. But this shouldn't stop us from developing some high-speed error-correcting traffic systems. One automated system with two ops sitting back drinking coffee should be able to handle more traffic than all of the Morse code nets in the country combined. If emergencies come, we're going to need modern services, not relics of the 1939s.

VIVA THE CODE!

One of our readers has come up with what appears to be a wonderful idea. He noted the strong support of the code for amateur licenses by a large part of the brethren and suggests that if this really is a necessary skill, amateurs should be retested at regular intervals to be sure that they have not lost their skill. I'm recommending that as a first-rate idea.

If anyone agrees with the majority of ARRL members that Morse code really is a necessary skill, let's see a petition to the FCC asking that every ham be re-examined every two or three years to make sure that he or she has not slipped in code skills. Or would every year be better? It sure doesn't take long to get rusty at the code, right? And I don't think you want anyone wasting our time on our valuable ham bands who managed to sneak through without knowing the code or who has gotten rusty.

You know, since there is such general agreement on the importance of code, perhaps we should start to take it seriously and stop being so namby-pamby about it. Is there really any reason why we shouldn't require everyone to move up a step in code with each re-examination? That would move all the Novices and Techs, who virtually don't know the code at all. At five words per minute you really don't have to have any code-handling skills... the skill comes in at 13 per, not at five. Okay, so let's make sure that we really do require the skills the majority agrees we should have... put our skills where our mouths are, so to write. Techs would then have to demonstrate an honest skill... 13 words per minute the second time down. And the third time they would be expected to show that they can copy at 20 wpm. I really don't see where anything less is honest or fair... if we are in agreement on the importance of code.

Well, you are saying (yes, I hear you), this just means that everyone can memorize the Bash tape translations, the way so many have been doing in recent months, and not even have to really learn the code. No, I'm willing to put the facilities of *73* at the disposal of the FCC... and at our cost, which is a heck of a lot less than they're paying right now... and turn out computer-generated Morse-code tapes, complete with an exam grading chart geared to each tape. That's a cinch. We'll just put about a hundred different on-the-air-type contacts on a disk and have a computer pick at random a call, name, QTH, rig, and so on for each tape, complete with an individual printout of the tape. No problem for us at all. We can grind out dozens of such tapes a day, each one entirely different, and the cost will be miniscule. If you agree that we really should get cracking with this code business in earnest, I'll get a bid in to the FCC to supply the tapes for them or for any clubs which give the exams, if we go that route.

Just think, if we stop pussy-footing around about the code and make sure that every ham has this skill, every one of us will be able to copy 20 wpm! The code is an absolute snap for me, always has been, so I'm 110% in favor of getting rid of all the old fogies who are too lazy to keep up this skill, one which a high percentage of you agree is important. And any Techs who are too busy gabbing on two meters to take off the few hours it takes to learn the code won't be missed... right?

I don't know why we should give people two years to increase their code speed when it takes just a few hours of work. Why not stop coddling the lazy and make it so you can get your Novice ticket at 5 wpm, then one year later you will have to have passed your 13 per, and a year after that 20 per. It makes a lot of sense to me, and I don't think you'll find anyone at the ARRL opposing the code.

Should we tighten up that schedule a bit? Giving new hams a year to increase their code speed will only tend to encourage them to put off practicing until the last minute. So why not make the last minute closer to the first minute and not have them fretting and fussing for eleven months and 28 days before starting to practice.

I haven't seen any recent figures on this, but I do know that a good friend of mine in New York has been teaching people the code from scratch at 20 wpm in one weekend. But let's agree that some people are a bit slower and might take a couple of weekends, and some might even have other things to do for one or two weekends which would keep them from practicing. Would a month do it? Certainly anyone seriously interested in his ham ticket can find a few hours in a month to get his code speed up.

You know, one of the saddest days in amateur radio was when the FCC under George Sterling, a ham and chairman of the FCC, forced us to have the Novice class license. The ARRL fought it tooth and nail and hated it, and still, as far as I know, doesn't really think of Novices and Techs as real hams. When I came into amateur radio, the first test was at 13 words per minute. That meant that you darned well had to really know the code and be able to copy it as a skill, not just by memorizing the characters and translating each one as heard as one does at five words per minute. *That* really isn't a code skill at all.

So let's petition the FCC to dump the 5-wpm test and start right out the way we used to at 13 wpm. *That* really proves some code skill. And then a month later, 20 wpm. That way we'll get all those darned CBers off our bands and stop all of the stupid pileups on DX, jamming on repeaters, bad language, and so on.

You know, most of the commercial CW circuits used to perk along at 35 words per minute. It probably takes a few weeks of practice to go from 20 to 35, but I'm not sure that is too much to ask any ham who is serious about this hobby. Let's have some letters on this. Should we go on up to 35 wpm for everyone... allowing perhaps six months to get there? Or is that too long? I'm 60 years old and as anyone will tell you, my brain is obviously going soft, but I'm sure I can get right on up to 35 per in a few weeks if we all agree on it. And you can bet that if I have to do that, I'm going to make sure that everyone else who comes along later isn't going to have to do any less, even if it kills the hobby.

So let's get together and put the no-code wishy-washies where they belong... on CB. And if they want to work DX, let 'em go on the 27-MHz HF band with the rest of the CW illiterates.

WHAT ARE YOU READING?

The results of a recent poll of the amateur radio community showed some interesting patterns. They're not really surprising, if you stop and think about it, but amid the flurry of claims and baloney flying around, it is nice to see what the surveys show is really going on.

To achieve a statistically valid survey, one can poll as little as a few hundred people, as you know if you've ever had to sit through a course on statistical analysis. That was not one of the more interesting courses I had to live through in college, but at least the experience did help to clear away the mystique of that field for me. In the *73* survey, we received responses from 5,720 hams, which is an overkill of about ten times that actually needed for dependable results.

Since we like to be sure that the content of *73* is right down the middle of the alley, so to speak, one of the questions had to do with how this content is perceived by hams with a comparison of how the content of the other ham magazines is perceived. Here's the result:

Mag	Too Complex	Just Right	Too Simple
73	6.1%	86.6%	7.3%
QST	24.9%	62.6%	12.5%
HR	32.6%	57.6%	9.8%
CQ	7.3%	57.3%	35.4%

Okay... what does that tell us? Looking first at the "too complex" column, we see that two of the ham magazines are turning off readers by making them feel stupid. Mind you, the material covered is not much more complex than is covered in *73*, it's just that the editors are not making the material easy enough to understand. It's the writing that makes it complex, not the material covered.

We hams, like anyone else, tend to be turned off if we are unable to understand what we are trying to read. And we also get bent out of shape if we think we are being catered to with condescending copy, which brings us to the "too simple" column. Isn't it curious that *73* did the best on both the "too simple" and "too complex"? No, not all that curious when you remember that our editors know what you want and see to it that the articles are neither condescending nor too esoteric in technical language.

Remembering that we're trying to be all things to all hams, there is no way to really get to 100% on "just right." There are always going to be newcomers trying to learn about what is going on who need to have plenty of hand-holding, so material must be made reasonably simple. Then there are the scientists who want to keep up with the state of the art and who will never admit even to themselves that anything is too complex. I'm not sure that anything much over 85% is ever going to be attainable, considering the wide variety of ham interests.

The perception of interest of articles obviously will reflect in an interest, or lack of it, in spending the money for a ham magazine. This brought about the next obvious question on the survey... asking which ham magazine, if any, the respondent had dropped during the past year. Almost one quarter of those surveyed had dropped at least one ham magazine subscription, so tha degree of interest of a magazine does turn out to be a most significant factor. Further, the dropping of subscriptions is unsurprisingly parallel to the perception the magazines are giving of their relevance to the ham reader.

The magazine dropped by the highest percentage of those surveyed was *Ham Radio*, with an 11% loss. This is consistent with the 32.6% "too complex" perception of the magazine. *QST*'s loss was second, running 9% and reflecting, one would suppose, the 24.8% "too complex" as well as the 12.5% "too simple"... and despite all of the pressure to "support the League, right or wrong." *CQ* fared better with only a 7% drop,

largely resulting, one would suppose, from the 35.4% "too simple" perception. *73* came out with only a 4% subscription loss, which might be considered as a minimum which is possible when you remember that there are going to be reader losses due to many factors other than magazine quality. There will always be non-renewals resulting from readers being out of work (which seems to have been a minimum for hams in this recession) or suffering from some personal disaster... such as getting married. We'll always lose a few.

What does this mean to you, the reader? Well, it means that we're giving you what you seem to like best in an article/column mix. Mind you, we're wide open for any ideas on change. *73* has changed substantially down through the last 23 years it has been published and will continue to do so. Older readers will remember back when the magazine first started and pushed the heck out of sideband. Then, when the so-called incentive licensing proposal was put before the FCC, we fought that, feeling that it would stop the growth of amateur radio and hurt the industry. Alas, we were right in that, even if powerless to stop the League at the time. Now we all have to live with the disastrous results of those black days... including the new management of the League.

Next we plugged for solid state while the other magazines were still pushing tube circuits, and then we pioneered FM and repeaters, at first a very lonely and controversial position. Our record is good for keeping you really up to date on new technologies and encouraging the building of ham gear.

Advertisers should find the results of the survey of particular interest, too. There is always the question of where it is best to invest in ads in order to reach the active, buying ham. The large number of retired hams getting *QST* has always made that magazine seem like a good deal for ads... after all, look at how many readers there are! It turns out there is a big difference between the buying interest of retired old-timers and active younger hams. Would you believe that surveys of *QST* readers have shown that about one-third of the subscribers don't even look into the welter of ads in the back of the magazine at all? Their equipment budgets are zilch, so why bother?

Speaking of ham buying, the recent survey showed very clearly the impact of the recession. The 5,720 hams surveyed said that they averaged about $567 each spent during the last year. When asked what they had budgeted for ham gear purchases for this year, they estimated an average of $640. This is the first time in several years that hams have said that they intended to go out and buy a lot more gear than they had in the previous year.

What are they going to buy? Unless the *73* readers are exaggerating, there are going to be a lot of low-band rigs sold this year... about 32,000 just to the *73* readers alone. The second product in mind for the readers is a new HF antenna... please make note KLM, Cushcraft, et al. Surprisingly, perhaps the third most wanted new item is a microcomputer, with an estimated 22,800 budgeted for purchase. That comes down to around $1M a month in computers just for the *73* readers, so we may be looking at a substantial rise in interest in RTTY and other computer-related communications.

At least 20,000 HTs are in the budget for this year and, with any encouragement from repeater groups, I'll bet that could be doubled.

By the time you add up what the approximately 150,000 readers of *73* tell us they are going to spend, it comes to around $7,5000,000 per month. Who says the ham business is dead? With that kind of market... and growing... I think we'll be seeing more and more small firms getting into the business to get a piece of the action.

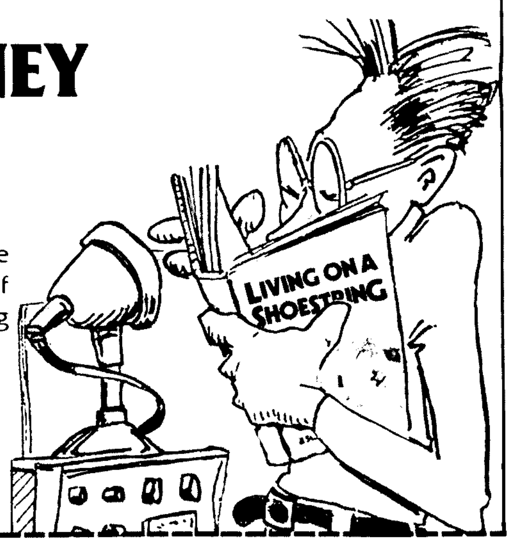
MAKE SAVING MONEY A WAY OF LIFE



With **LIVING ON A SHOESTRING:** A Scrounge Manual for the Hobbyist. Almost anything you find can be put to good use if you follow the techniques of a master scrounger. George Ewing shows you how to:

- Find electronic parts
- Scrounge by the rules
- Scrounge a vehicle
- Locate tools and other surplus
- Read up on scrounging
- Scrounge a place to live

Cartoons and case histories of scroungers add a humorous touch. With **LIVING ON A SHOESTRING**, you can't always get something for nothing, but you can certainly get it for less. $7.97 Softcover, 7 × 9, 128 pp. approx., ISBN 0-88006-059-X

Call TOLL FREE 1-800-258-5473 for credit card orders. Or mail your order with payment or complete credit card information. Include $1.50 for shipping and handling. Send to:

Wayne Green Inc.

NEVER SAY DIE
editorial by Wayne Green

THE DAYTON DAZE

Two of the manufacturers exhibiting at Dayton were in a heated argument as I passed by, with one holding that the Hamvention officials were lying through their teeth about the attendance... that there certainly were no more than 27,000 hams there instead of the 30,000 official count at that time. Well, during the rainy early Saturday morning, I'll tell you this: You could hardly move from one place to another.

Once the sun came out, the hordes poured into the flea-market area and eased the pressures a tad. It was still crowded inside, but at least you could move around.

After trying to communicate with a packed roomful of people last year, fighting the thunderous noises from the two adjacent meeting rooms and what seemed like 100° heat and humidity, I wasn't even going to try this year. But the Hamvention people suggested I give it another try in a more isolated room... and at a more isolated time. So I got up there on the podium Friday afternoon, before many of the brethren had yet arrived for the hamfest, and did my stint. It was better, but still marginal. Next year, I'm told that there will be some new meeting rooms where we'll have quiet.

Since many of those present indicated that they preferred a stiff code test as part of our amateur entry fee—never mind what the lack of growth has done to our country, with the loss of one consumer electronics industry after another, a loss getting up into the dozens of billions of dollars a year... and never mind what this is doing to us in the way of military weakness (it's better to lose the country than acknowledge the changes in technology and cope with them)—keeping that in mind, I came out strongly in favor of Morse code and was met with great enthusiasm.

Fine... let's by all means go with what everyone wants, no matter how destructive it is. Let's make it so that we put our licenses where our mouths are ... if code really is important, then let's make sure that each and every ham has to requalify every year and prove the ability to copy.

None of this silly five words per minute. *That* isn't code! That's baloney. The ability to copy code starts at 13 per, so that should again be made the irreducible minimum. That should be the starting speed. But then, remembering that we are now agreeing that code is of high importance, can we honestly support anything other than a new "incentive licensing" plan which will move us on up to at least 35 words per minute? Any ham really worthy of being a ham should be able to get to that speed in a few weeks... so let's set that as the ticket for holding your license.

Many of those present were nodding eagerly in total agreement, licking their chops at the thought of being able to knock 90% or more of the hams out of the hobby and back into CB where they belong. When I suggested 50 wpm for everyone, they were wildly enthusiastic. That could easily knock out 98% and QRM would be a thing of the past. Good grief, we might even have enough room so that we could go back to spark!

A couple of spoilsport women, obviously too lazy to really care about being hams, got mad over this and stormed out of the room. They probably never learned the code anyway... being licensed by a good friend who overlooked that little requirement.

The talk was fun.

In looking around the exhibits, I noticed that good old Bash was there, but everyone was giving this booth a wide berth. There were even some chaps talking about a "trash Bash" move to stop this prostituting of the ham ticket. And not a few hams came to me wondering what all the fuss about no-code was when with the new Bash code tapes one could pass the code test without even being able to copy the code. I had a good friend who got his Extra ticket that way. He had only slight ability to copy code... and virtually no theory understanding. He just wanted to see if one could Bash one's way to success without knowing a damned thing and was greatly surprised when he walked out with a lovely one-letter call suffix.

The development of ever smaller Morse-code readers has brought us to the tiny hand-held decoder. With that, anyone can copy code at almost any speed... certainly up to around 100 words per minute. If we can take that in with us for the license exam, that should solve the whole code problem... right? Oh, I can hear the purists bitching... "Yes, but what if the battery burns out?" We heard the same complaint when kids started using hand calculators instead of learning their multiplication tables. The answer to that is so simple: *solar power.*

They have inexpensive solar power cells which can run the decoder just from the glare of a Morse-code fanatic's eye. So

QSL OF THE MONTH

This eye-catching card from Lalo Santos HK3EQJ in Bogota, Colombia, easily outshined the competition to win this month's QSL card contest. This colorful card features a modernistic shack resembling Mission Control, a motif which is reinforced by the large dish in the background and a quad antenna which literally sparkles. Further back, the stars shine over a haloed sun setting into the Andes mountains—a scene which would be beautiful from any shack.

If you would like to enter *73*'s QSL of the Month Contest, enclose your card in an envelope and send it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries without an envelope or book choice will not be considered.

let's stop worrying about the code, okay? It has turned out that kids do just fine without memorizing the multiplication tables. Those calculators don't wear out much...and solar power keeps 'em charged.

Speaking of the code, for those who think the code can be fun, AEA has a new gadget which will drive you crazy. They showed the first version of it last year at Dayton and this little bugger simulates a CW contact with you. Now they've updated it and you're in there fighting with a bunch of other stations trying to work some rare DX...all done by computer. I see this as a great gadget for hamfests to use for simulated DX contests. Hotshot DX ops can sit down at a DX simulator and see what kind of a score they can make in ten to twenty minutes of operating. That should be a ball.

With more and more of the CW ops using keyboards and code copiers, unless we stress the fun of the code, we may find that few, if any, hams are actually able to copy the code anymore. Almost all of the high-speed CW you hear on the bands these days is computer-generated and -copied. The Novice bands still have a few people hanging around chirping out half-hour CQs, hoping that no one will answer.

OTHER DAYTONIA

Out in the outer fringes of exhibitors, I was surprised to find a booth run by the CIA. It seems they are pepping up their communications facilities and are in need of technicians. I've got some pretty good friends who went into this kind of work and they've certainly had interesting lives as a result. If you're the kind of person who likes to travel and see unusual places, this might be worth checking out.

Icom was wowing 'em with their 1200-MHz repeater. It's set up for FM use, but I'll bet if they modify it a bit so that it will handle television, they'll have a bunch of customers. Ham television really should be up on 1200 MHz and not crammed onto one channel on 420 MHz.

And both Kenwood and Yaesu had new rigs which were showstoppers. You'll be seeing reviews of 'em here as soon as we can get our mitts on the rigs to check them out. Ten-Tec had a nice little 2m HT which I suspect is going to be very popular. We've been promised one of those soon, too.

The Hamvention is always a seething mass of hams going around the exhibits and then scouring the enormous flea market for bargains. If the show gets any bigger, I don't know where they could put it. The poor old Hara Arena in Dayton is just plain overwhelmed. Cars fill almost every neighboring field and the huge lots at the arena and line the streets for almost a mile around. The people in the neighborhood are uptight over the cars, but when about 30,000 hams descend on one place, it takes a lot of parking to handle 'em.

There was some sort of hassle over the flea market not being opened on Friday and a good deal of flak went up over that. And just to make the situation worse, the opening on Saturday was accompanied by a deluge. It cleared off in the afternoon just fine, but there were an awful lot of very unhappy fleas for a while.

Ohio has a new law aimed at getting tax payments on sales by flea-market exhibitors. This is mainly for the few professional flea-market salespeople who make a living at it and have been thus avoiding paying the stiff Ohio sales tax. The Hamvention crew shelled out $5 each for the flea-market exhibitors to keep the authorities off their backs. I think they remembered the problems at Rochester, where the police came in and virtually closed down the flea market... and the regular exhibitors, too. That disaster almost ruined the Rochester Hamfest, which has been struggling to get back to strength ever since then.

For a show of its size, the Hamvention went very smoothly. It's three days long and it takes you that much time to really see just the inside exhibits, much less cover the flea market...which had about 600 exhibitors this year, I understand. Nine in the morning until eight at night is a grueling job for the poor exhibitors, but perhaps it's worth it so that everyone has more of a chance to see everything. It's only once a year.

REAL HAMS

One thing the mail about the proposed code changes has made crystal clear is that there still are a substantial number of Real Hams around, despite the decimation of our ranks by what the communists called "incentive licensing."

For instance, the Real Ham does not use sideband...that's for wimps. The Real Ham sticks to the Real Ham communications mode: CW. Oh, the Real Ham gets on two meters, too, but no Real Ham signs his call more than once every half hour or so. After all, the Real Ham only talks to damned good friends...other Real Hams... and everyone knows who's who by the voices, so who needs an ID? The more often you sign your call, the more of a wimp you are. And no one but a leaping faggot would prissily demand that the breaker identify himself.

Real Hams, when they develop Parkinson's Disease, which a growing number of them have, and can no longer make that old straight key talk, do go on phone...but you can be damned sure they go on AM, not wimpy sideband with the ducks and other fruits.

Real Hams have a key in one hand and a six pack of cool 807s by the other. They eat pretzels while hamming and steak and potatoes for dinner. Pringles? You've got to be kidding! You ought to have your keying hand mashed in the door for even thinking such an obscene thought.

DANGEROUS DXING

Alas, I didn't see any mention of amateur radio in the news reports of the ill-fated Spratly DXpedition. You've probably read about it. It had to do with a group of German DXers heading to Spratly on a catamaran. They unfortunately managed to find the islands and were shot out of the water by the Vietnamese, who killed one of the DXpeditioners. The other five drifted for nine days in a dinghy, with one dying of dehydration before the rest were picked up.

As I recall, the last bunch of DXers who tried to get Spratly off the endangered DX list got shot at, but not with quite such disastrous results. You'd think that DXers would take a look at history before going to Spratly.

The first ham to put Spratly on the air, back in the 60s, the chap who invented the 1S call (much to the annoyance of the ITU), figured out how to get all the contacts he wanted from there without all that danger. As far as I know, he did his entire Spratly exercise from up in central Thailand, the same place he used to make his Burma and Cambodia exercises, I suspect. I have the cards from those operations and they are acceptable for DXCC.

DXpeditioning used to be a lot easier...and more fun...when the ARRL didn't put hams in danger of their lives. No one really gave a damn whether the DXpedition was exactly precisely where it claimed to be or not.

Continued on page 124

You Can Build This Code Trainer

More than a mere code-practice oscillator, this CPU-controlled trainer features burned-in practice groups. Flick a switch and you have a keyer.

If you are a ham who wants to upgrade or a ham to be, or if you know someone who wants to be a ham, there is now a low-cost, single-chip microcomputer for you. It is called the CPP1. The CPP1 is a single-chip microcomputer that contains copyrighted software for teaching Morse code. It also doubles as an electronic keyer (iambic) for added versatility.

The unit can be built in one evening. This makes it ideal for the time-pressed person who would rather be involved with amateur radio than with computer technology. Virtually everything is contained on the chip except the dot clock and the tone generator. These are built around the low-cost 555 timer chip.

Learning Morse code using tapes and records is a frustrating experience. It's difficult to concentrate when you have to keep stopping and rewinding to the beginning of a particular practice group. Also, tapes and records never seem to have the right speeds to practice at. They are either too fast or too slow.

Personal computers are far better. However, their cost is a problem, especially

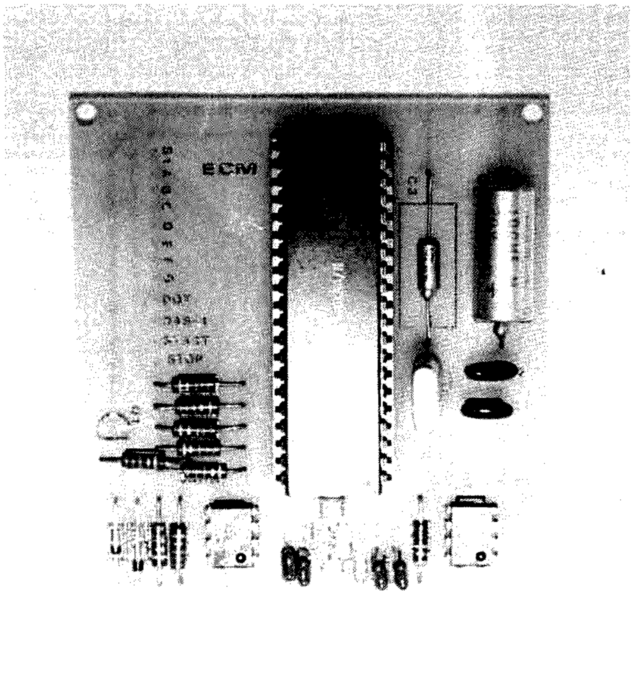

Photo A. The CPP1 circuit board.

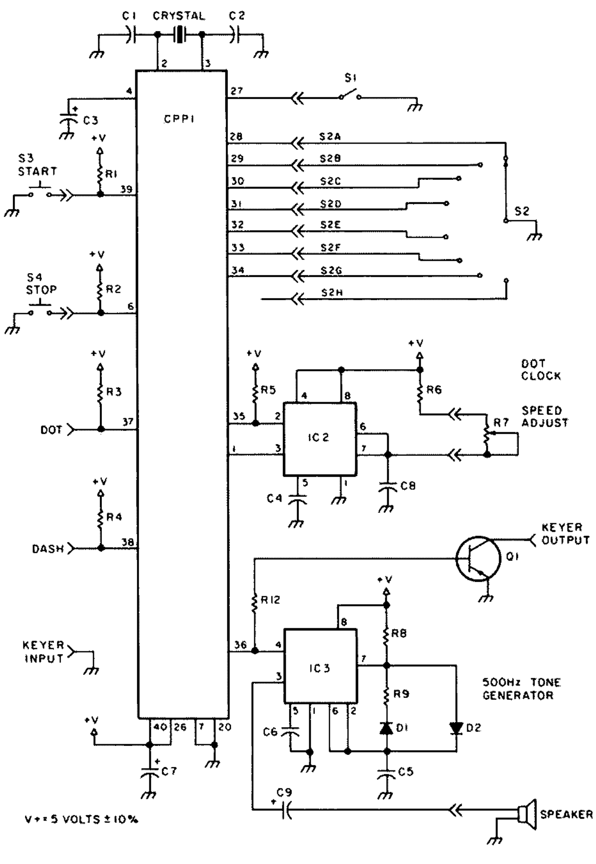

Fig. 1. Schematic.

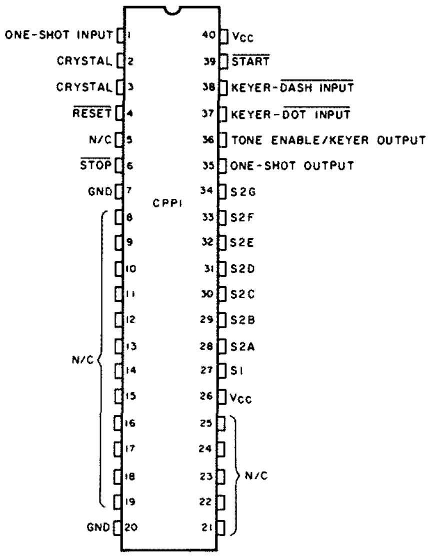

Fig. 2. Pin description.

if your budget is tight. In addition, most people do not have the technical or software knowledge to make this approach viable.

The CPP1 solves both of these problems. The chip contains 15 practice tables. They are organized to provide for ease of learning. When a particular table is selected, it will repeat until the user decides to move on. Speed is virtually unlimited, however; with the components called out later, the processor will send perfect code from 2 wpm to over 40 wpm. Finally, it is simple to use. No need for a degree in computer sciences to use it; just select and go.

Circuit Description

The heart of the code trainer/keyer is the CPP1. Contained in this 40-pin package are 128 bytes of RAM, 2K of ROM, an 8-bit CPU, a reset circuit, a clock, and predefined I/O ports. It is a true system on silicon.

To get the CPP1 to function requires a simple crystal/capacitor addition to pins 2 and 3 of the processor (see Fig. 1). The crystal can be from 1 to 6 MHz. A 3.57-MHz color-burst crystal is recommended because of its availability and low cost.

In order to ensure proper start-up, the chip contains a reset circuit that holds the processor in a known state until power is stable. The chip must stay reset for at least 50 milliseconds. This is accomplished by capacitor C3 on pin 4 of the CPP1. When power is applied, the capacitor will hold this line low. An internal pull-up resistor will then start charging the capacitor. When the capacitor reaches a high level, the processor function will start.

The processor at this time will set the I/O ports up per its internal program. It will then start testing the start button for a closure (pulled to ground). When a valid switch closure is recognized, the program will next test switch S1 to see if it is open or closed.

Switch S1 determines which table is to be executed (see Tables 1 and 2). If switch S1 is open, Table 1 will be selected. If switch S1 is closed, Table 2 will be utilized.

Next, the processor will test switch S2 to determine which subgroup to run. There are a total of 8 subgroups per selected group. Seven require that one of the pins, 28 through 34, be pulled to ground through switch S2. The eighth group is selected when all eight pins are open.

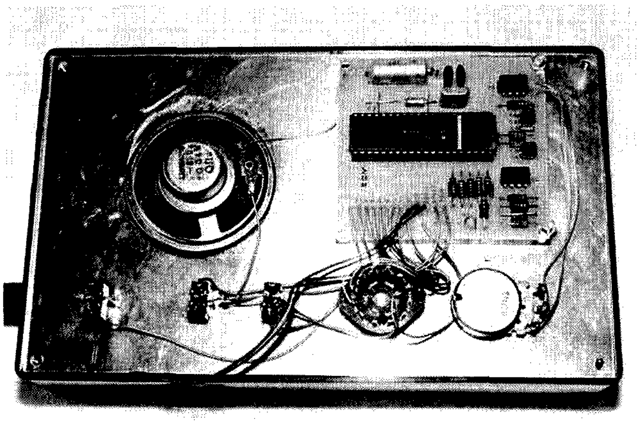

Photo B. The inside top panel of the CPP1.

Upon determining which subgroup has been selected, the processor will start sending at the rate of the dot clock, IC2. All timing is based on the dot clock.

The processor will send out a short pulse from pin 35 of the CPP1 to fire the one-shot (IC2). It will then test pin 1 for it to time out. This is one dot time. For dashes, it will do this three times.

The tone is generated by IC3, a simple 500-Hz tone generator. Pin 36 of the CPP1 will go to a high level whenever the tone is on; it

goes low to turn it off. To stop the sequence, pin 6 of the CPP1 must be pulled to ground through the stop button. (It should be noted that the start and stop buttons can be either normally-open push-buttons, as shown in Fig. 1, or toggle switches.) At this time, the processor will start testing the start pin again, except in the keyer mode.

In the keyer mode (switch S1 and S2 open), when the start is pressed, the chip will enter the keyer mode. To leave it, the power must be turned off. This is to eliminate any chance of the keyer going out during transmission.

Construction

Assembly is very straightforward. The circuit can be hand-wired in about an hour or two, or a simple single-sided PC board can be used.

The crystal should be located as close as possible to the CPP1. This is standard for any microprocessor.

C7 must *not* be left out. This stabilizes the power to the chip when the tone is on. If it is left out, it is possible that the internal program will jump out of sequence.

Custom tailoring the CPP1 to your particular needs can also be done. Some examples are:

- replacing the speed control with a rotary switch with fixed resistors,
- replacing R9 with a potentiometer for tone control, and
- adding a volume control.

These are just a few of the many variations possible.

Operation

The CPP1 is extremely easy to use. Apply power. Set switch S1 to the appropriate practice table. Set switch S2 to the desired subgroup. Press start and adjust speed. That's it!

Your selected practice group will cycle until stop is pressed. At this time, another practice group can be selected. Speed may be adjusted any time.

To use the keyer function, set both switches S1 and S2 to the open position. Then press start. You are now in the keyer mode.

When pin 37 is brought to ground, a series of dots will be sent. When pin 38 is brought to ground, a series of dashes will be sent. Finally, when both pins 37

and 38 are held to ground, alternating dots and dashes will be sent.

A final operating note concerning speed: Selecting the proper speed for practice may be done in one of two ways. The simplest way is counting dots. This is accomplished by setting the CPP1 to the keyer mode and pressing start. Hold the dot input line low and count the dots for one second. Once the number of dots per second has been determined, it is a simple case of calculating the speed by the following formula: speed (wpm) = 2.4 × dots/sec. For example, if 5 dots are counted in one second, then speed = 2.4 × 5 dots/sec = 12 wpm.

The second method is based on a known fixed resistor value. Since all timing is based on a dot time, it is a simple matter of using the following formula for determining the one-shot time: dot = 1.1 × (R6 + R7) × C8.

Conclusion

Learning Morse code, or increasing one's speed, has been a problem since the early days of ham radio. Learning Morse code should be fun and easy. However, traditional means using tapes and records generally make it less than desirable.

The CPP1 puts learning Morse code into the computer age without the hassle. Using the CPP1 makes learning code fun and easy. Using this device 15 or 20 minutes a day, followed by listening to actual ham conversations for about the same amount of time, will make code learning exciting and rewarding. ■

Parts List

QTY		ICs

The True Story Behind Heard Island

Fighting bad weather, shady ship owners, and bad press, the HIDXA expedition forged its way to the DXer's dream. But getting there was only half the battle.

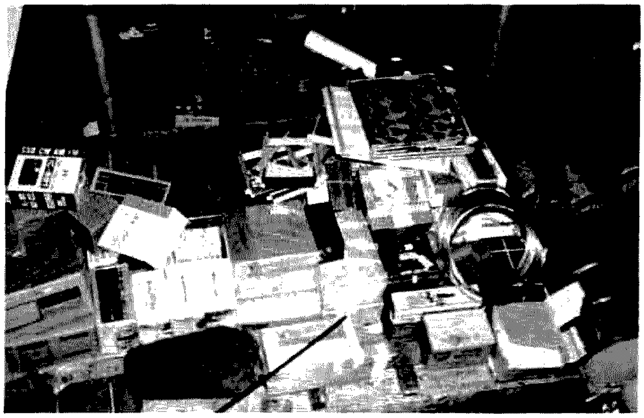
The idea of a possible DXpedition to Heard Island came to Jim VK9NS while he was still P29JS and living in Papua New Guinea. Heard Island, in the southern Indian Ocean, is situated in one of the world's stormiest seas, uninhabited, inhospitable, and not really "en route" to anywhere. So the only way to get there would be to catch a lift or charter a vessel for the voyage. The vessel would have to be sturdy and suitable, with an experienced skipper for those waters. The cost for such a lengthy trip would be high, but if the money could be found, such a DXpedition could take place. So the Heard Island DX Association (HIDXA) was formed early in 1980, and the long and stormy road to Heard Island commenced.

Assistance was asked for, and many an amateur contributed. Jim, in his dealings with the authorities, met with goodwill and interest from all concerned. A set of guidelines was formulated for private expeditions visiting Heard Island, and he got permission to visit, pending a firm proposal. License for Heard Island was issued —VKØJS.

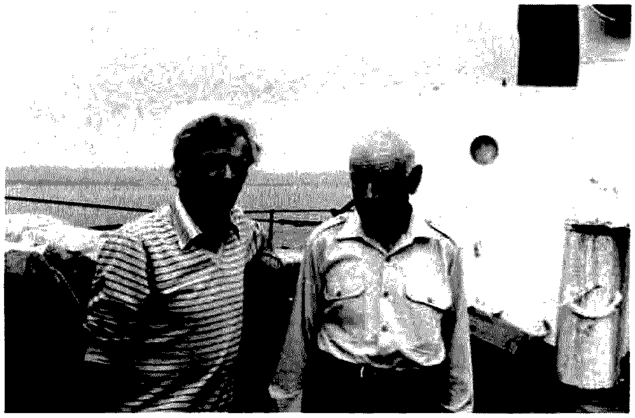
Meanwhile, the hunt for a suitable vessel was on, and word was out for interested operators. The season for visiting Heard Island is very short, involving January through March of each year. A vessel was in fact found for the 1981 season, but the enormous cost involved could not be met at the time, and this very suitable charter and experienced skipper had to be abandoned.

Unfortunately, HIDXA was now led astray by promises regarding a West Australian shipping firm who said that they intended to send a fishing-survey ship to Heard Island waters in the 1981 season and would take a group of amateur radio operators along for a reasonable sum of money. This proposal sounded just too good to be true, and of course, as we all know, it turned out to be just that.

Preparing for departure.



Equipment and stores in the hold of Cheynes II.



Jim and Tom VK6MK in Albany.

Months of not knowing and being put off with "we will know for sure next week" persisted until the season was over. During 1981, it was a continuation of "next week for sure," regarding plans for 1982, until it became clear that "next week" would never come. We heard that Dr. Lewis might be going to Heard Island on the *Dick Smith Explorer* in 1982 and we had berths booked on that ship should they be headed that way. As it turned out, they went to Antarctica instead.

So the hunt for a vessel for 1983 went on. The problem was mainly financial. People do not really want to give money to a project which is not 100% guaranteed. Money might be promised *after* the expedition, but shipowners want payment in advance. So we were really faced with a sort of "catch 22."

Now came the surprising news that IDXF and NCDXF had pledged $20,000 in order to send 2–3 operators along with a group of mountaineers who were planning an expedition to Heard Island to climb Big Ben. At the same time, concentrated efforts to discredit HIDXA and statements that Jim would never go to Heard Island and had no intention of even trying began to appear on the bands. Jim had always stated that if the expedition did not take place, he would refund donations. Four out of 300-odd persons who had donated to HIDXA asked for their money back; so it goes to show that most people do not take as gospel truth whatever they hear on the grapevine.

SoJo VKØSI spent Easter of 1982 on Norfolk Island. He and Jim spent long days working on the Heard Island project. SoJo proved himself to be just what we needed most—someone with know-how, interest, and "get up and go." He went back to Tasmania and started looking for a vessel. Jim was reluctant to go on the air and say "we are going in 1983" until he was fairly certain that this time it would happen. So it was not until early September of 1982, when the contract with the owners of the ex-whale-chaser *Cheynes II* had been signed, that we could really start our publicity campaign. We sent out masses of brochures, "stuffers," and letters. Now that the vessel was secured, it was smooth sailing ahead. The beauty of this contract was that the vessel was big enough to take up to 20 passengers. So, if we could find even 10–12 people with other interests, and 6–8 operators, with all of us paying $3000 out of our own pockets, we could pay nearly the whole charter cost.

Universities were informed of this chance to visit Heard Island and advertisements were placed in several Australian newspapers. Gradually, the team started to take shape. A firm proposal to the government was drawn up. This was several pages long since it had to include details of all personnel, equipment, landing gear, supplies, etc. But once submitted, it did not take long for the official blessing to come through in writing.

Meanwhile, on the bands, word had it still that we would never go and were just daydreaming, that the ship was a floating coffin, it was no good, etc. Some of the DX outlets took the trouble to print some of the material we had sent along, but others must have filed it straight into the wastepaper basket since their publications were quite innocent of any mention of HIDXA. IDXF and NCDXF, on the other hand, were never out of the news!

There was talk of "the race to Heard Island" in those publications in which we did rate a mention. It was of course never a race. It was a matter of two groups, with different objectives, going more or less at the same time. We were just continuing what Jim had started in 1980. No doubt the mountaineering group had also been planning for some time, but without amateur-radio involvement, the world of ham radio would not know. Heard Island was high on the "wanted" list and you could probably put five successive groups on the island, all of whom would work tremendous pileups. For goodness sake, we work endless pileups from Norfolk Island where there are 6 licensed resident amateurs! So this "race" idea was a bit silly. One publication topped that by advising its readers to "put their money" on IDXF/NCDXF, as if we were horses. It passes all understanding, for sure.

We got a lot of support from individual amateurs in many countries, and we received a lot of encouraging letters with the donations, so we knew we had the support of the individual amateur. Some of the small DX clubs also contributed, but the big clubs did not come forward; an approach to NCDXF proved futile. The lack of publicity left many in doubt as to our intentions. When we received $100 from LIDXA, it was with a stern request to send the money back should the expedition not take place. We had already paid $6700 as a deposit on the *Cheynes II*, but they received our money-back guarantee in writing.

The cost of an expedition to such a place as Heard Island is immense. Apart from the remainder charter cost which was paid by the expeditioners themselves, HIDXA had to find money for fuel, landing gear, food, generators, tents, tarpaulins,

Do we go on or don't we? Chief Mate and Skipper make the decision.

Battling headwinds on the way to Heard Island.

gas cookers, gas, and a number of bits and pieces. A suitable first-aid kit and supply of pharmaceuticals had to be provided. Rigs and antennas were mostly on loan, but with a guarantee to return or replace them if lost, thus requiring expensive insurance in addition to the freight cost. It made me wonder about certain people's sanity when I heard inane remarks about "going on an expedition to get rich." The idea that a green stamp with a QSL card is clear profit and it costs nothing to mail a card back is fondly believed by some people.

Life became very busy from September through December. Jim left for Tasmania in November to be on the spot for all the last-minute arrangements that had to be made. I remained on Norfolk Island to handle incoming correspondence and hold the fort. We kept in touch via radio or telephone, but with everything else on our minds, we both forgot our wedding anniversary on December 5; 2 years—you would think we had been married for 20.

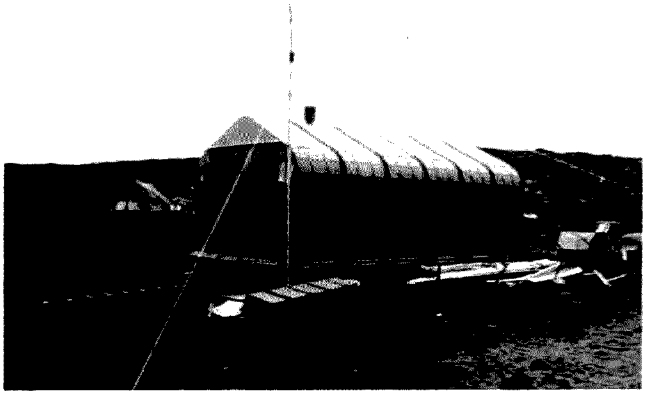
I arrived in Tasmania on December 29. Those last few days before departure were very hectic. What with the holiday season and all the festivities, it seemed impossible to organize the final details, and departure had to be postponed for a couple of days. The rest of the team had already arrived. We were 17 people, including 5 scientists, 5 mountaineers, a journalist, and a cinecameraman. A mixed group for sure, but as it turned out, a very balanced group. We all got on well with each other. Maybe the fact that each and every one of the expeditioners was required to pay $3000 ensured that no one who was not very strongly motivated and did not really want to go to Heard Island was included in the expedition. We could have filled the ship with people who wanted to come for nothing, but our policy did not permit any freeloaders who might cause arguments and backbiting if the going got rough. A very wise move as it turned out.

Peter VK6VR, Walter OE1LO, Kirsti VK9NL, SoJo VK0SI, Bernie VK6KI, and Walt W7SE at Albany.

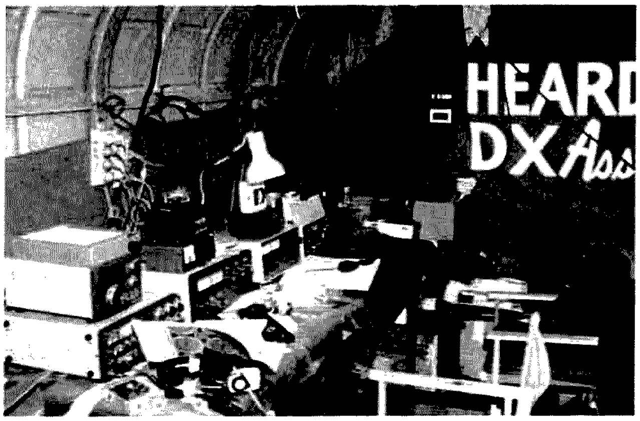
Our troubles should now have been over, but this was not to be. We departed Hobart January 4 and struck a strong gale immediately. After battling ahead for 24 hours, the skipper advised that due to the high rate of fuel consumption and slow progress, we should return to Hobart to await more reasonable weather. Turning around in those mountainous seas was a frightening experience. The *Cheynes II*, which had been tossing around violently for hours already, now laid over momentarily to a 40° angle which sent everything crashing and broke the lashings on the two dinghies stowed on the foredeck. During the night, a wave had shot up under the boat deck and knocked a 3" plank clean out, so it was a slightly battered *Cheynes II* that returned to Hobart the following morning.

We now had three days of hanging around Hobart, impatiently waiting for the weather to improve. It did improve somewhat, but we still stayed with no explanation forthcoming. Finally, we were scheduled to leave on Sunday morning, but Saturday evening we learned that departure had been postponed once again since the skipper/owner had decided not to come with us. A new skipper was found, and on Sunday afternoon, Captain Laurin MacEwan arrived and we were off again.

The southern route was abandoned. We took a westerly course while the skipper made himself familiar with the vessel. He soon found that the fuel consumption was alarmingly high. It bore no relationship to facts and figures quoted on our dealings with the company. In fact, Captain MacEwan found that we could not go to Heard Island from Hobart. The ship just did not have the range, in spite of all the expert advice and calculations which had been done by professionals. The only thing to do now was either to cancel the expedition or go to Albany, in western Australia, to refuel and make Heard Island from there. Naturally, we all agreed it would have to be Albany. There was no question of the ship not having the range for that distance. The mystery of the fuel consumption followed us all the way. Tanks were dipped



Our home on Heard Island.



VKØJS shack.

and charts consulted. Nothing seemed to add up. It was a worry for several days before they thought they had the problem licked.

We continued our voyage after refueling in Albany, and for some days everything ran smoothly. We settled down to a routine for shipboard life. All expeditioners were rostered for duty in the galley or on the bridge. Three would do the cooking, with cooks changing each day, and normal 4-hour watches were kept on the bridge, around the clock. The expeditioners got to know each other and the crew of 8, and with so many people with different backgrounds and experiences, there was always a lot to talk about.

Unfortunately, one of the operators, Walt W7SE, found it necessary to withdraw from the expedition in Albany. By then we were already so much delayed that he just could not risk further delays which would make him late back for work. Another scientist joined us in Albany so the number of people remained the same.

It now became apparent that we did not have enough water on board for the boilers. This was another mystery, but nevertheless a fact. We were supposed to carry 170 tons of water, but in fact, had only about 80 tons, another reason why the vessel did not have the range. The only thing to do now was to call in at Kerguelen Islands to take on water. This would cost us extra fuel which we could ill afford. Arrangements were made with the owner that he would meet us on the way back with the necessary fuel to take us back to port in Australia.

Thus, we made a stop at Kerguelen. The French were kind and helpful. It seemed to us that we had been at sea for a lifetime, when in fact, it had been just two weeks since Albany. We had a lot to learn yet! The French invited us all ashore for lunch, and we savored every morsel of that meal. There was of course no chance of operating from Kerguelen. It was an unplanned-for port of call, and the necessary license could only have been issued in Paris, well in advance. In any case, we stayed only a few hours, so time would not have permitted operating from there.

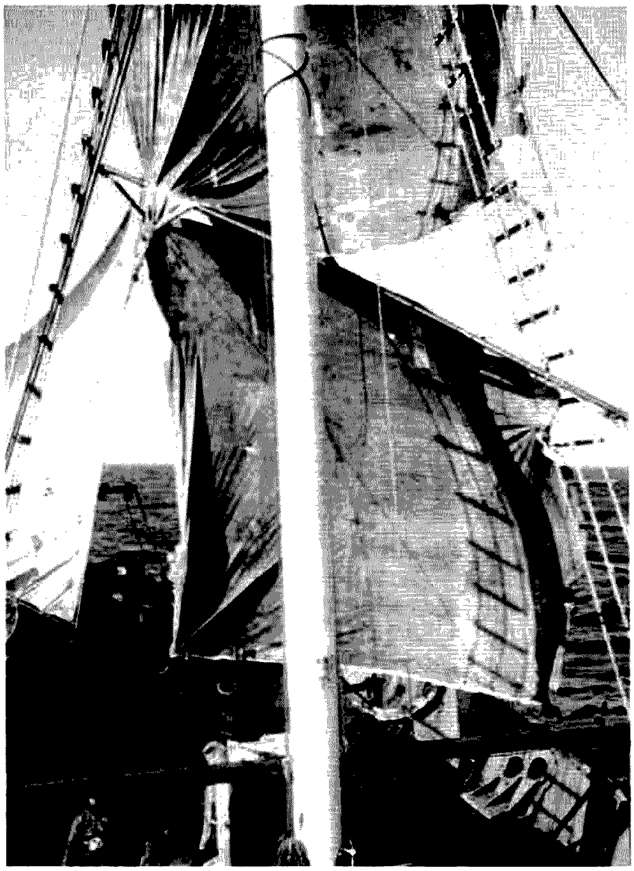
Once again the expedition nearly came to a full stop. The *Cheynes II* dragged anchor and we could hardly believe our eyes when we dismally observed her drifting onto the rocks. It was very fortunate that nothing vital was damaged and we were able to continue on to Heard Island.

Finally, on February 5, there it was: Heard Island. We arrived in rain and mist, but it was reasonably calm, so unloading commenced right away. Plans for landing equipment and personnel had been made during the voyage. All gear and food had been wrapped securely in plastic and sealed, so offloading went smoothly. We had had breakfast at 4:30 am in order to make an early start.

Now began a back-breaking day. We had two Arbec huts for our use. The scientists and film crew settled into the one closest to the beach, and the hams had the other, smaller one up the hill. These huts are mere shells of unlined metal. They are completely devoid of furniture or amenities. But, they were waterproof even if somewhat drafty. Our hut was about 500 meters away and every bit of equipment, antennas, food, gas, cookers, generators, etc., had to be hand-carried all the way from the beach. The trips to and fro were many, and I think we had all reached the stumbling stage by the end of the day. It rained; the black volcanic sand stuck to everything and the path was rocky and uneven. Finally, the beach was empty and we could think about getting a rig on the air and see about sleeping space and something to eat.

It was dusk by now. Our hut did not have a door. In spite of the rain which now came in torrents, the icy wind in the doorway, and the cramped conditions inside the hut, we got ourselves into some sort of order. Bob got one of the generators going and with a vertical antenna he was ready to open up from VKØJS. His first QSO went to ZS6IW. He worked some Europeans, but with the rain pouring down onto the unprotected generator, there suddenly was a power surge

The day the sun came out; Big Ben.



Tarpaulins made makeshift sails for the Cheynes II.

which put a stop to operations. We all retired to our sleeping bags. Being utterly exhausted, we slept extremely well.

I was the first one awake the next morning. Jim, SoJo, and Bob looked like three blue elephant seals in their sleeping bags. It had stopped raining, and soon we were all busy putting up more antennas, making the hut more livable, and getting properly organized. A 3-element ten-meter beam and a 3-element 15-meter beam were unpacked and erected without any trouble. We had brought a Minooka Special for 160 meters, but unfortunately, even with all expeditioners lending a hand, putting up this huge vertical proved too much in the strong wind. She bent beyond repair and had to be abandoned. The TH3 tribander was the last one to go up, complete with rotor. The other beams had a hand-operated turning arrangement. One of the tents was put up to house the generators, and inside the hut, Jim hung other tents to keep some of the draft out, the final one being hung in the doorway to act as a door. We had four rigs ready for use and had brought spare rigs just in case.

A solar flare made radio conditions extremely poor. I suppose we were lucky it did not put a full stop to propagation for the duration of our stay, but it was very unfortunate that it had to happen at all. We worked. One of us would monitor the bands and call CQ regularly. If there was an opening, we knew about it and made the most of it. Openings sometimes lasted only a few minutes, but after a few days, we found that 20 meters was usually open to America in the early morning hours. Europe was around in the evenings, and Asia and Pacific at odd times during the day. Nighttime was a bit unpredictable, but we kept watch on the bands around the clock.

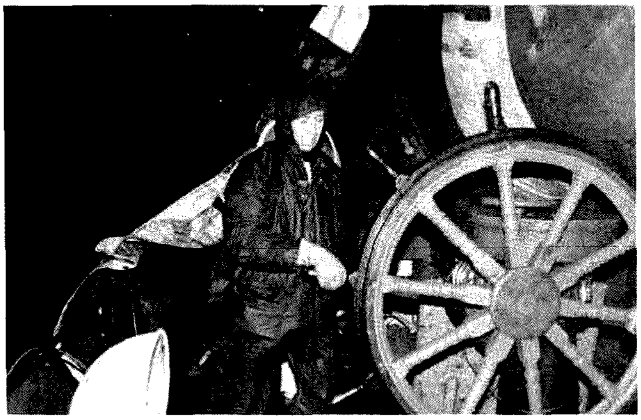
We were now joined by Walter OE1LO, who had been helping the mountaineers get started on their climb up Big Ben on a new route from Mechanics Bay. With the poor band conditions, we were more than enough operators, and some of us actually just sat idle most of the day. SoJo was in charge of all RTTY and SSTV gear and made the first QSO ever from Heard Island on these two modes. He also made the first satellite QSO from Heard Island. So, by making use of every little opening, the number of QSOs crept up. VKØJS made about 12,400 QSOs, with VKØNL making about 2000. This was not a bad score in poor conditions.

The *Anaconda II* operators were also active. This meant that only one of our stations could operate on whatever band happened to be open. If VKØCW was on 20 meters CW, then we could only be on 20 meters SSB instead of having one station on CW and one on SSB. This, of course, applied to the other group as well.

Bob took charge of the generators. He kept them going, serviced them, refueled, and did some repairs. None of us got a tremendous lot of sleep. The shack was noisy, cold, and cramped. But the days passed quickly. We were more or less self-contained in our hut, being able to do the basic cooking there and not having to leave the bands to turn up for meals in the other hut. Not very sociable, but time did not allow for socializing. In fact, when the other three ladies of the expedition were invited aboard the *Anaconda II* for dinner one evening, I was not even asked. At least I like to think that this was because everyone knew the hams were too busy to socialize! (It could have been those shapeless oilskins combined with my advanced years, of course.)

So we worked. The scientists took samples from penguins, counted them, measured temperatures on rocks and under rocks, collected samples of this and that, and generally had a very successful time on the island. The mountaineers climbed their new route towards the summit of Big Ben, keeping in touch by VHF skeds twice daily. The film crew filmed everyone and everything and will have an excellent documentary of the whole fantastic voyage and stay on the island, to be released on Australian TV in June/July, 1983. It is expected that this film will also be released overseas in due course.

We had hoped to extend our stay a few more days, but due to the precarious fuel situation on the *Cheynes II*, this could not be. So we were due to depart February 15 at 1600. In preparation for this, we started to carry some things to the beach, intending to keep one rig on the air till the bitter end. However, the wind was quite strong, and by lunchtime, a full storm blew up. This was the Heard Island we had feared. Atlas Cove boiled; sea spray was blown far inland. Ashore, the black volcanic sand whipped and blasted. The *Anaconda II* operators lost their beam; the mast just buckled effortlessly. It became clear that departure was impossible and we made our way down to the beach to make sure the gear already there was secure. Here, we found that the seas were rising and everything had to be moved further up—an enormous task in that wind. Gusts were measured up to 80 knots and some of us were literally blown off our feet. At one stage, I was sent flying and ended up underneath the tarpaulin which we used to cover the goods. The *Cheynes II* had to get up steam to keep from drifting



In oilskins and mittens, doing the dogwatch while under sail.

onto the rocks, and the skipper told me later that he had never before seen the wind actually blowing big holes in the sea the way it did that day.

Things could have been worse. The storm could have lasted until the *Cheynes II* was out of fuel for that matter. As it was, she burned up a considerable amount that day and the next, but the wind did abate and we were finally able to get on board on the 16th at lunchtime.

It was a hurried, cold, and blustery departure. The island looked extra miserable with sleet and snow settling on the black hills. The ride out to the ship was bumpy and frightening for those who cared. I did not; I was exhausted and retired to my bunk and refused to come out for the remainder of the day!

Heard Island is a unique island, black and white with a bit of moss covering some of the rocks. There are no insects to speak of, just a wingless fly and a wingless moth. Seals and penguins are the permanent residents, and there are many birds. We found time to go for short walks and see the sights. One day when the weather was very mild with sun breaking through, the island looked beautiful in its own stark way. But the climate is miserable. As I had it explained to me: It is not that it gets so cold, it is just that it does not get warm enough for things to grow. There is very little sun—mostly rain and mist. With a summer temperature around +5° C, only 8 vascular plants and some mosses and lichen represent the growth of millions of years.

I would not mind going back some day, but on a guaranteed vessel—guaranteed not to run out of fuel and to be unsinkable. The *Cheynes II* is probably very close to unsinkable. She proved that she could perform some amazing feats—standing up on her hind legs and laying over on her side, all in one quick motion. But . . . there was the fuel/water problem. I was dimly aware of talk of sails and so forth but had been too busy to think about it. Now it had to be faced. After two days steaming, the engines were shut down and sails were hoisted on the foremast. The "sails" were actually our tarpaulins which were made fast to yardarms welded together on board from bits and pieces. With no engine, we had no electricity, so the emergency steering gear on the open afterdeck came into use. The wheel itself was enormous; it took two people to turn it before the grease worked its way through. A compass was laid to rest on a lifebelt inside a drawer which was tied in front of the wheel. A small wind sock above indicated how the wind was in relation to the sails (which we could not see), and appropriate chalk marks on the tiller flat showed how much helm we had. Thus, 400 tons and 160 feet of iron steamship became a square-rigged sailing vessel!

We were still far south since this was where the prevailing wind and current could be used to our advantage. Sometimes the speed was less than 1.5 knots, but at other times, we reached a stunning 4.5 knots. The albatrosses settled down to paddling in our wake, and we kept studying the foam alongside to try to guess if we were moving or not. It was very uncomfortable, cold, and dark, with watchkeeping done on the afterdeck more frequently now since two of us had to be on duty each period.

Incredibly, we inched our way ahead. I think the worst of it all was the bitter, cold wind and the dark. The diesel generator would run for 3-4 hours each evening to charge the batteries on the bridge. This was the highlight of the day when I would rush to our cabin and switch on the bed lamp in the hope that the warmth from the globe would perhaps yield a bit of warmth to the pillow before bedtime.

After 13 days of this, the boilers were fired up and the engine restarted, since we expected to meet the owner with the promised fuel and water in a couple of days time. However, after two days steaming, we learned that the refueling ship had been delayed. This was a great disappointment. Another 3 days of sailing, and at last, after 855 nautical miles under sail, we made the rendezvous. Another pie in the sky; there was no refueling—we were to be towed home. A 1000-foot line was attached, and we continued our cold and dark existence for yet another 7 days although we did not have to stand watch on the open deck.

For reasons best known to himself, the owner now instructed the skipper to forbid amateur radio on *Cheynes II*. He "did not want any talk about what was going on" was the comment we heard. No other reason was given. I am not sure exactly what it was he did not want us to talk about, but it seemed pretty silly, since anyone could make a Radcom call and talk his mouth off to anyone. And the news media were interested. They even hired a plane to come out and see for themselves, a couple of hundred miles off the coast.

We had started to run out of some foods. The variation in meals was not great in the end, but we were not in any immediate danger of starving. It was a matter of look-

The Saxon Onward *takes us in tow.*

ing at the bright side. For instance, without butter, margarine, or cooking oil, washing up in seawater became mere child's play since we had no greasy dishes. And with not much to cook, the cooking chore became fairly simple. As the trip was supposed to have lasted a maximum of 42 days, and we had eaten well for 72 days, I would say that in this important area at least calculations had been liberal. Even when we finally berthed in Albany, West Australia, there were baked beans, tinned tomatoes, and packet soup left over. We could in fact have spent a few more days at sea but were certainly happy not to be obliged to do so.

During all our trials the group stayed together. The mood in the mess room remained lighthearted and cheerful, and no one allowed him/herself to show any short-tempered ill feelings which so easily could have jeopardized the easy-going comradeship which reigned. In any case, any short temper would have been caused by minor irritations and would not have been worth showing off. We were literally "all in the same boat" and knew it.

Nearly home and relaxing in the sun: Jim VK9NS, Kirsti VK9NL, Walter OE1LO, SoJo VK0SJ, and Bob WA8MOA.

The whole expedition had been an uphill battle with problems arising one after another for months before we even left Hobart. To top it off, we found that evil tongues had been wagging on the amateur bands while we were battling our way home. "They have lost the logs" was the cry. Was there no end to it all? Jim took the unprecedented step of having the logs sighted by Tom VK6MK, in Albany, as proof that we had not lost them. Tom subsequently advised WIA that the logs were intact. How can anyone stoop so low as to start such rumors? Especially someone sitting snug and comfortable in his safe home thousands of miles away from Heard Island or *Cheynes II*? How do they explain their "knowledge"? The only explanation I can think of is that someone is determined to discredit HIDXA at any cost—even at the cost of their own honor and credibility. Why? What are they afraid of? Is amateur radio a hobby or has it become big business?

The Heard Island and *Cheynes II* experience was no picnic. We did it because we wanted to activate Heard Island and had said we would do so. And as my granny used to say: "What does not kill you will make you stronger!" ■

More Stable Than a Rock

An Honorable Mention winner in 73's Home-Brew II Contest, this 10-MHz generator is a sure cure for the drifting frequency blues.

Ralf Beyer DJ3NW
Opferkamp 14
3300 Braunschweig
Federal Republic of Germany

Have you ever followed the conversation of two guys on the same frequency using identical several-thousand-dollar transceivers but reading off different frequencies from their digital displays? Or did you ever wonder how to estimate the drift of your own frequency counter when making frequency-drift measurements on your new rig or project just finished?

Of course, there are various means to overcome these problems. Temperature-controlled ovens as an option for your frequency counter, for example, are readily available. They will give the crystal in your frequency counter a short-term frequency stability on the order of 0.1 ppm. However, they lead to an increasing uncertainty about the actual accuracy due to the aging process in the crystal—and they cost 50 dollars or more.

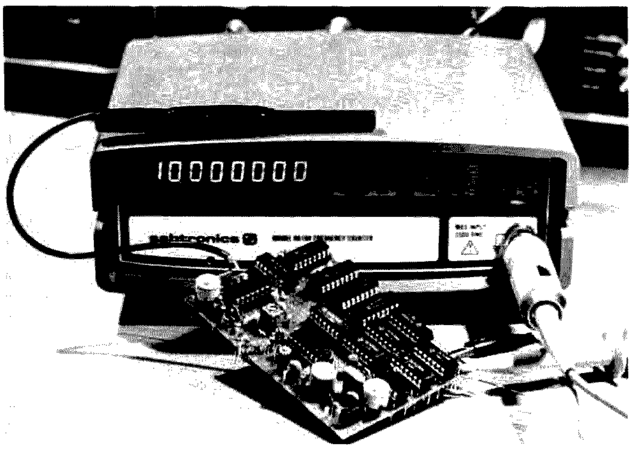
On the other hand, precise frequency reference signals are delivered more or less free of charge to our shacks by the National Bureau of Standards or by means of TV signals synchronized with a cesium standard.

It is not to everyone's taste, however, to deal with fading signals from a distant standard-frequency transmitter or to hook up a TV set to a frequency counter. So there must be another way to take advantage of precise reference signals generated elsewhere but which are already easily available in the ham shack.

The Basic Idea

In almost every populated area of the country, at least one AM-broadcast station in the 450-1800-kHz band is available which is strong enough to be heard even in the basement of a building or in the concrete jungle of city centers. All the care necessary to maintain a stable transmitting frequency has been taken at the radio station already, so there is no need to start all over again.

Usually, the radio stations maintain a stable frequency



The circuit in actual operation, with the ferrite antenna on top of the counter. Output frequency is 10 MHz, phase-locked to a selectable AM-broadcast station.

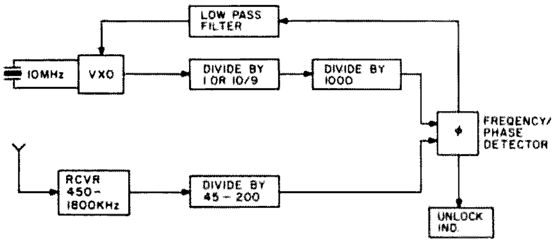


Fig. 1. Basic concept.

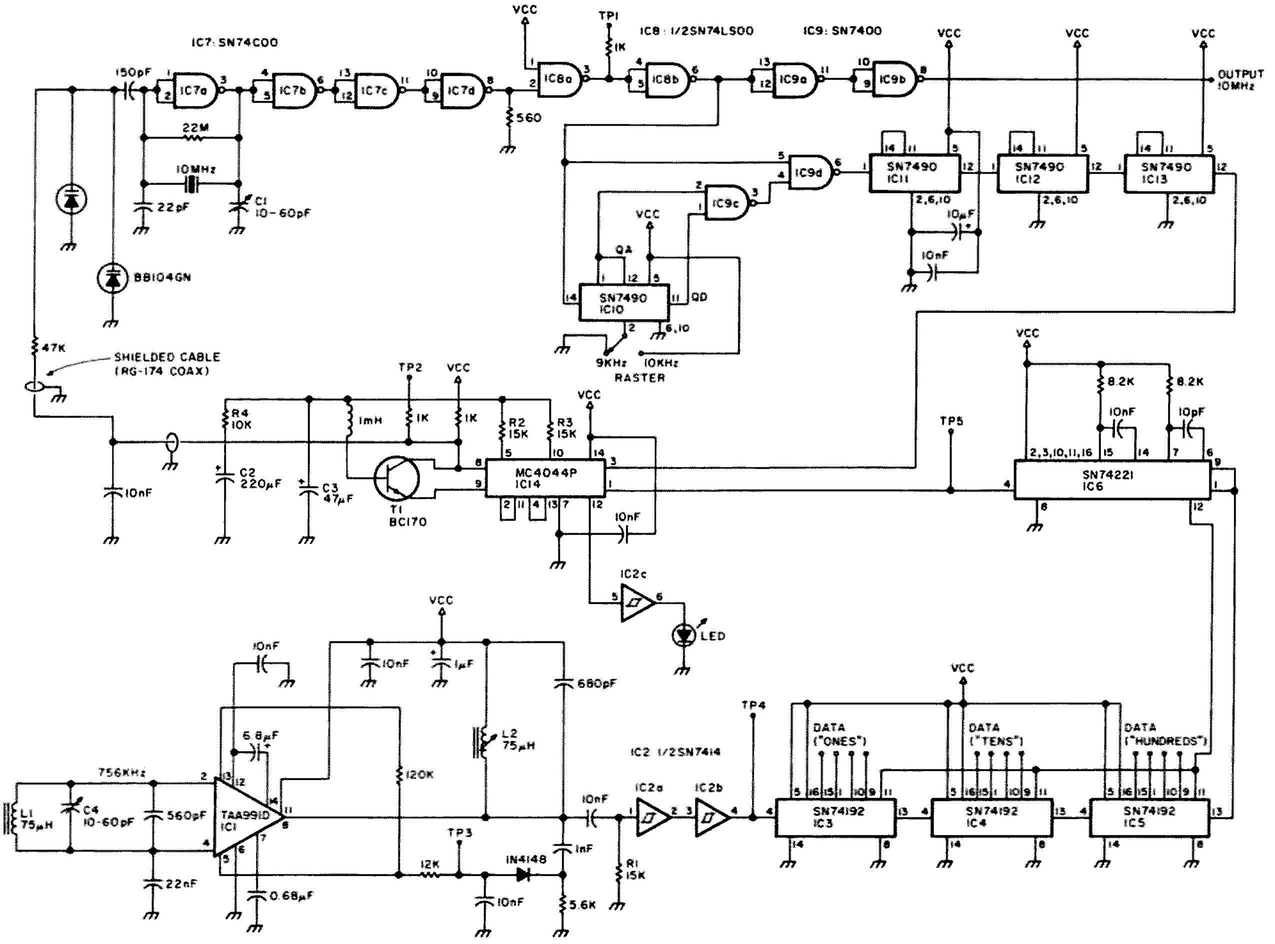

Fig. 2. Schematic diagram.

by means of a crystal oscillator whose frequency is regularly checked against and aligned with a reference frequency from the National Bureau of Standards or a secondary source of a reference frequency of similar accuracy. Even better, the ultimate step has already been taken by phase-locking the radio transmitter frequency to a reference frequency of the National Bureau of Standards.

The transmitting frequency of the Deutschlandfunk (DLF), phase-locked to a frequency standard generated by the PTB, the German National Bureau of Standards (Physikalisch-Technische Bundesanstalt), is one example. The PTB transmission on 77.5 kHz has a frequency stability of better than 10^{-6} ppm per day (10^{-12}).

Due to variations of propagation, the frequency of the signal received 300 km away from the transmitter still is accurate to better than 0.01 ppm (10^{-8}) or 0.001 ppm (10^{-9}) for measuring periods of 1 and 10 seconds, respectively.[1] But while a short-term stability of station DLF on the order of 0.0001 ppm (10^{-10}) is achieved by a well-regulated crystal oscillator, the small variations of the received reference frequency are filtered out by a very slow response of the frequency-control circuit resulting in a long-term stability in the same order of the broadcast-transmission frequency.

Most frequency counters and secondary frequency standards use a 10-MHz crystal oscillator as a master clock from which other time signals or frequencies are derived. And many frequency counters and signal generators already have a provision for synchronization or triggering by an external frequency standard.

My basic idea, therefore, was to build a 10-MHz crystal oscillator, phase-lock it to an AM-broadcast transmitter of high frequency stability, and use it as a virtually drift-free frequency/time signal generator of high accuracy for frequency counters, calibrations, etc. Some of the design specifications were:

- The unit should be programmable to accommodate the AM-broadcast frequencies of interest.
- It should be small enough to fit into existing equipment without employing large external antennas, thus maintaining portability of the equipment.
- It should generate a 10-MHz TTL signal with an accuracy similar to the accuracy of the AM-broadcast transmitter employed, i.e., with a short-term stability of at least 0.01 ppm (ten times better than an oven-stabilized crystal oscillator) and an even higher long-term stability.
- It should be programmable for the 10-kHz raster of AM-broadcast transmission frequencies employed in the US and for the 9-kHz raster already in existence in Europe.

The basic concept is shown in Fig. 1. A simple receiver picks up a signal of an AM-broadcast transmitter in the 450-1800-kHz range. The carrier frequency is isolated from the modulation and fed to a frequency divider with a programmable division ratio of 1:45 to 1:200.

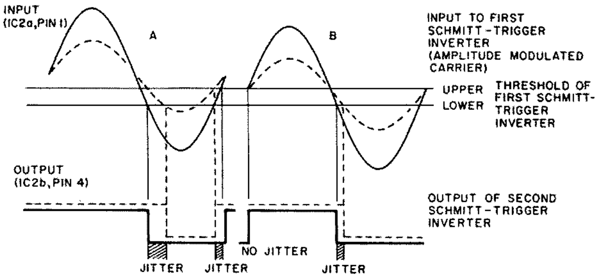

Fig. 3. Operation of the two Schmitt-trigger inverters. (a) Without a pull-down resistor, the input signal resides on the high input level of the first Schmitt trigger. Both edges of the output pulse of the second Schmitt trigger are jittering due to the amplitude modulation of the input signal. (b) The high input level of the first Schmitt trigger is pulled down by a resistor. Triggering occurs at the zero-crossing point of the rising edge of the input signal resulting in a jitter-free rising edge of the output pulse of the second Schmitt trigger.

For the 10-kHz raster of AM-broadcast frequencies employed in the US, a range of division ratios from 45 to 180 is selected to yield a 10-kHz signal at the output of the divider. For example, for station WJR in Detroit on 750 kHz, the division ratio would be set to 75, and so on. For the European raster, a range of division ratios from 50 to 200 is selected to yield a 9-kHz output signal. A ratio of 84, for example, divides the carrier frequency of station DLF on 756 kHz to 9 kHz. The 10- or 9-kHz output signal is fed to a frequency/phase detector as the reference frequency.

The desired 10-MHz signal is generated by a variable crystal oscillator (vxo) whose output signal is frequency-divided in a pre-divider by 1 (US) or by 1.111 · · · (Europe) and then divided again, by the main divider chain, by 1000 to yield an output signal with a frequency of 10 kHz (US) or 9 kHz (Europe). This variable frequency is fed to the frequency/phase detector, too, which produces a corresponding error signal if variable frequency and reference frequency do not coincide regarding frequency and/or phase.

The error signal is passed through a low-pass filter in order to remove the 10-kHz (9-kHz) components. The dc component of the error signal is applied to a varactor diode in the vxo to pull its frequency up or down as required. This dynamic process comes to a rest when both frequency and phase of the variable frequency from the vxo and the (constant) reference frequency coincide on the 10(9)-kHz level, which in turn produces a steady control voltage for the varactor diode in the vxo.

Any tendency to leave this steady state due, for example, to a change of ambient temperature and its impact on the vxo frequency is immediately balanced by an appropriate change of the amplitude of the error signal, thereby keeping the vxo on phase and frequency with respect to the reference frequency (phase-locked loop). An "unlock" indicator signals if phase-lock has not been achieved.

The Circuit

The complete schematic diagram of the circuit is presented in Fig. 2. The simple AM-broadcast receiver consists of the integrated circuit (IC1) designed for the front end of AM/FM receivers. Various types of applicable ICs are on the market. The TAA991D chosen here operates from a 4.5-11-volt supply; it has a voltage gain of 90 dB and an agc range of 60 dB.[2] The TAA991D amplifies the signal of the AM-broadcast station received by the ferrite antenna, L1, to about 4 V_{SS} at its output.

The very efficient gain control accommodates a wide range of input-signal amplitudes and can cope even with very strong signals of nearby broadcast stations. Furthermore, the time constant of the gain control is kept so short that it also compensates carrier-amplitude variations due to the modulation. Measurements showed that an amplitude modulation of the carrier frequency of more than 90% is reduced to less than 5% by the circuit, resulting in an almost steady carrier signal at its output.

Most AM stations modulate far less than 90%, however. The output signal of the gain-controlled amplifier is ac-coupled to a Schmitt-trigger inverter, IC2, which is pulled down at its input by resistor R1 to a level of about 1.3 volts.[3] The value of R1 should be adjusted so that the rising edge of the sinusoidal carrier signal triggers the Schmitt trigger at or near its zero-crossing point (see Fig. 3). Thereby, the modulation of the carrier is removed almost completely, resulting in a jitter-free falling edge of the Schmitt-trigger output signal. At the output of the second Schmitt trigger, IC2B, a jitter-free rising edge is obtained which triggers the programmable divider which follows.

The programmable divider is a chain of three binary-coded decimal (BCD) up/down counters, IC3-IC5.[3] Generally, the incoming carrier frequency can be divided by any integral number from 001 to 999. However, as mentioned earlier, only the range from 045 to 200 is needed. The "ones" of this number are represented by the first counter (IC3), the "tens" by the second counter (IC4), and the "hundreds" by the third counter (IC5). Pins 15, 1, 10, and 9 of each counter accept the respective digit number in BCD form. If these pins are in logic state 1 (i.e., connected to V_{CC}), their contribution to the digit number is 1, 2, 4, and 8 respectively. If they are in logic state 0, they do not contribute at all.

For example, if the carrier frequency of station WJR on 750 kHz is to be divided down to 10 kHz, the number to be programmed is 075. In this case, the logic states of pins 15, 1, 10, and 9 are 0, 0, 0, 0 for IC5, 1, 1, 1, 0 for IC4, and 1, 0, 1, 0 for IC3, in that order ($0\times1+0\times2+0\times4+0\times8=0$, $1\times1+1\times2+1\times4+0\times8=7$, and $1\times1+0\times2+1\times4+0\times8=5$ all together corresponding to 075). As the three counters are wired as down-counters, the number 075 loaded this way is reduced by 1 for each cycle of the incoming carrier signal.

If number 000 has been reached, an output pulse at the output of the counter chain (pin 13 of IC5) is generated which is used to reset the counters to the state programmed initially (075 in the example). The very short output pulse is stretched to approximately 50 nanoseconds by one of the monostable multivibrators of IC6 and applied to reset pin 11 of each counter.[3]

Because only one output pulse is generated for 75 input pulses, a division of the carrier frequency by 75 is achieved. The other monostable multivibrator of IC6 which follows stretches the length of the 10-kHz output pulse to about 50 μs for further processing. For the European raster of AM-broadcast stations, the same considerations apply. The carrier frequencies are multiples of 9, however, and a reference frequency of 9 kHz is obtained by division of the carrier frequencies by integral numbers from 50 to 200 in order to utilize AM stations in the range from 450 to 1800 kHz for the same purpose.

The vxo consists of a low-cost microprocessor crystal and one CMOS gate (IC7, same pinout as IC8[3]) as the active device. The double-varactor diode, BB104 green, has a capacity swing from 35 pF at 3 volts to 14 pF at 30 volts of reverse bias. Any other varactor diode of similar characteristics is applicable. For a voltage swing from 1.5 to 5.0 volts at TP2, a frequency deviation of approximately +60/−95 Hz from the nominal frequency of 10 MHz was measured. Initially, trimmer capacitor C1 is adjusted so that an error voltage of about 3 volts is measured at TP2 for a vxo output frequency of 10,000,000.0 MHz.

Several inexpensive crystals were tried out with appropriate readjustment of C1, and they gave similar good results. The CMOS level of the vxo signal is converted to TTL level by the combination of one low-power Schottky gate (IC8A) and a 560-Ohm pull-down resistor at its input.[3] Another gate (IC8B) is used for buffering the 10-MHz signal. It is further buffered by TTL gates IC9A and IC9B and passed to the 10-MHz output terminal.

As the 10-MHz signal is going to be checked against a reference frequency of 10 (US) or 9 (Europe) kHz, it must first be divided by 1 or 1.111 · · · giving a frequency of 10 or 9 MHz. The chain of three decade counters (IC11-IC13[3]) which follows divides that frequency down to 10 or 9 kHz and this signal is passed to the frequency/phase detector as the variable frequency together with the 10- or 9-kHz reference frequency from the AM-broadcast receiving branch of the circuit.

The alternative division by 1 or 1.111 · · ·, respectively, is achieved by the combination of decade counter IC10 and gates IC9C and IC9D.[3] If pin 2 of the decade counter is high, i.e., at V_{CC} level, the counter is disabled and its output terminal (pin 11) is in a low state. Consequently, the output of gate IC9C remains high constantly, enabling gate IC9D which passes the pulses from the output of gate IC8B directly to the input of the chain of decade counters. No frequency division takes place in this case (division by 1). However, when pin 2 of the decade counter is in a low state (grounded), the counter is operative. Its action is explained in Fig. 4.

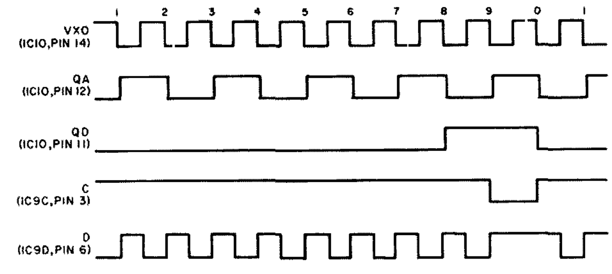

Fig. 4. Operation of the divide-by-1.111 · · · module as explained in the text.

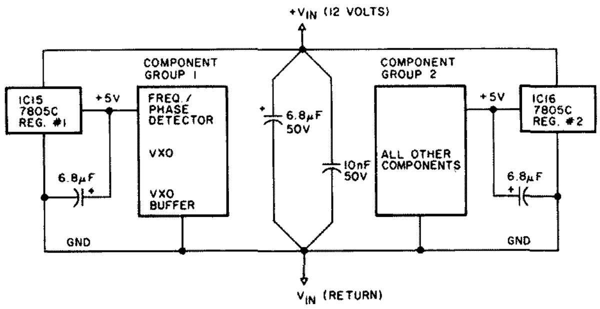

Fig. 5. Power supply.

The counter contains a chain of four flip-flops with designations Q_A for the output of the first and Q_D for the output of the last flip-flop. For the arrangement shown in the schematic, the first flip-flop is triggered by each negative transition of the vxo pulse sequence. Q_D assumes a high state after 8 input pulses and is reset to a low state after 10 pulses. This constitutes one complete cycle of the decade counter. The logic combination of outputs Q_A and Q_D by gate IC9C produces signal C at its output. And the logic combination of signal C and the signal of the vxo by gate IC9D generates a sequence of pulses (D) similar to the signal of the vxo with the exception that for every 10 pulses of the vxo one pulse is missing. Therefore, 9 pulses are generated at the output of gate IC9D for 10 pulses of the vxo, constituting a division by 10/9 = 1.111 · · ·.

The frequency/phase detector, IC14,[4] checks the frequency/phase difference between the reference frequency and the variable frequency, i.e., the AM-station carrier frequency and the vxo frequency, respectively, both divided down to 10 (US) or 9 (Europe) kHz. 10(9)-kHz pulses appear on pins 5 and/or 10 with a duty cycle corresponding to the difference. These pulses are filtered by a low-pass filter (R2, R3, R4, C2, C3, 1-mH choke) and buffered by transistor T1.

Any small signal transistor is applicable here provided it has a gain high enough to meet the following specifications: no frequency/phase difference generates a voltage of about 3 volts at TP2; a higher frequency or a leading phase of the variable frequency (vxo) with respect to the reference frequency generates voltages of down to 1.5 volts or up to 5 volts in the contrary case.

This error voltage is applied to the varactor diode of the vxo which pulls the crystal frequency to achieve zero frequency difference and a very small but constant phase difference. At pin 12 of IC14, negative-going pulses are generated whose duration is proportional to the phase difference of variable and reference frequency. They trigger the Schmitt-trigger inverter, IC2C, which turns on an LED in case of a wide pulse width indicating that a no-lock condition exists.

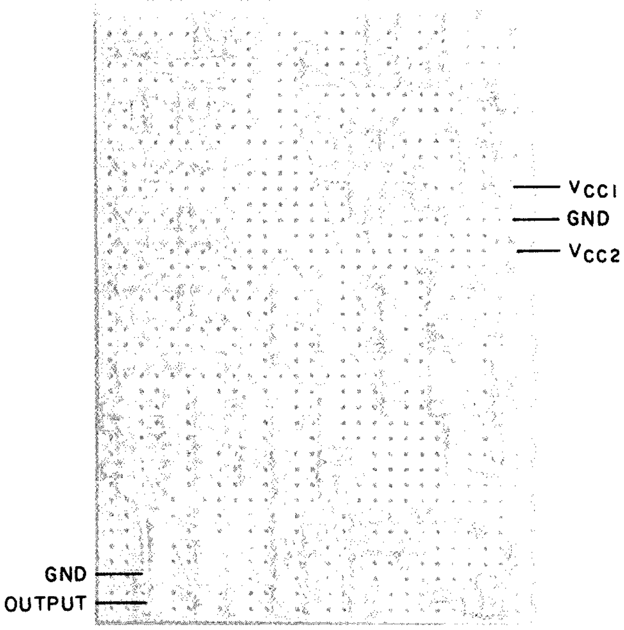
The Power Supply

In the power supply, two regulators are used. One serves the most critical component group, i.e., the frequency/phase detector, the vxo, and the vxo buffer, IC8A/B. The other serves a group containing the remaining components. All ground-return leads in each one of the two groups are returned to their common ground—and a heavy wire is recommended here. Fig. 5 presents the general arrangement of the power supply. Regulator #2 needs a bit of heat-sinking. At V_{in} = +12 volts, regulator #1 has to deliver approximately 50 mA to component group 1 while regulator #2 delivers approximately 330 mA to component group 2. Total power consumption is 4.6 Watts (12 volts at 380 mA).

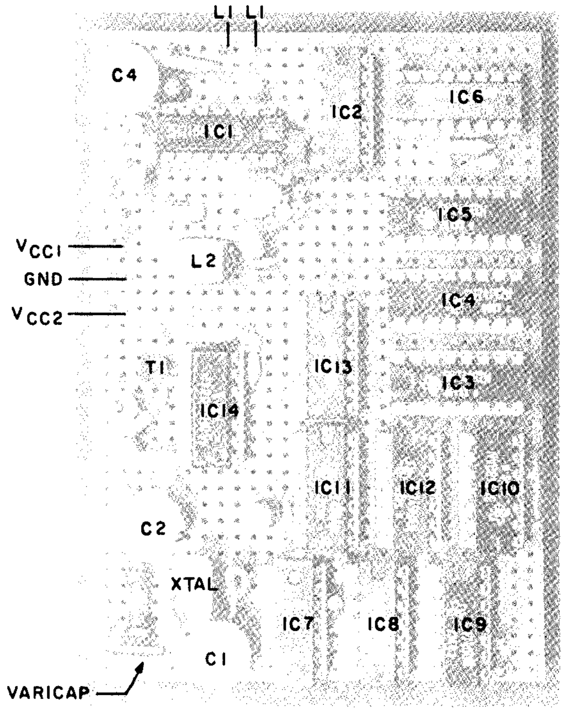
Construction

The whole circuit was mounted on a perforated board of 68 × 100 mm (2-5/8″ × 3-7/8″) size with solder eyes and 0.1-inch spacing. The discrete components were soldered directly on the board in an arrangement which minimized the number of additional interconnecting wires. For the integrated circuits, wire-wrap sockets were used, and this part of the circuit was wire-wrapped.

Miniature binding posts



Bottom side of board.



Top side of board.

were inserted in the perforated board where needed. The whole circuit board may be mounted in a miniature cabinet 71 mm long × 102 mm wide × 28 mm high (2-3/4" × 4" × 1-1/8"). In this case, both regulators are mounted directly on the inner surface of the cabinet. However, the board may be installed directly into existing equipment. In case of a metal cabinet, the ferrite antenna must be mounted externally.

Alignment

The test instruments used for alignment were a VOM with an internal resistance of 20k Ohms/volt, a Sabtronics model 8610A frequency counter with an HP 10006 A 10:1 test probe (14 pF/10 megohms), and a small pocket receiver to check whether the broadcast station to be utilized is on the air.

First, the receiver is aligned by measuring its agc voltage at TP3 and tuning the input and output circuit of the receiver for maximum agc voltage. The negative agc voltage should be at least 0.6 volts and may run as high as several volts depending on the strength of the AM station received. The component values shown in the schematic diagram were chosen to receive a station on 756 kHz.

With the frequency counter at TP4, one should obtain a stable indication of the carrier frequency of the AM-broadcast station selected. If the display is not stable within one bit of the last digit of the frequency counter, make sure that the counter is not disturbed by residual modulation of the carrier, line noise, or other signals.

Next, program the appropriate number into the three count-down counters (IC3-IC5) which follow to obtain a 10(9)-kHz reading on the frequency counter at TP5.

Now connect the frequency counter to TP1 and the VOM to TP2 and adjust C1 so that the frequency counter displays 10-20 Hz more than 10 MHz (if the VOM indicates more than 3 volts) or 10-20 Hz less than 10 MHz (if the VOM indicates less than 3 volts initially). Allow the frequency/phase detector up to 30 seconds to recover from saturation and observe the VOM. The error voltage measured at TP2 should stabilize at about 3 volts within 60 seconds with the unlock indicator turned off and the frequency counter displaying 10,000,000 Hz, 9,999,999.9 Hz, or an overflow to (1)0,000,000.0 Hz depending on its accuracy. If the error voltage stabilizes elsewhere, adjust C'1 of the vxo to achieve an indication of 3 volts.

Finally, adjust C1 so that an error voltage of 3.2 volts is indicated. This finishes the alignment of the circuit.

Performance

The performance measurements were made with the same test equipment already used for the alignment of the circuit. First, the frequency counter together with the 10:1 test probe was checked. An undesirable sensitivity of its internal clock generator to TTL signals at its input could not be found. However, it was sensitive to heavy line noise, so a 12-volt car battery was used to power the frequency counter.

The frequency counter had an internal voltage regulator for 5 volts, but no drop of battery voltage occurred during the time of measurement. After warm-up, the counter was connected to TP1 of the circuit and its internal clock aligned for a display of 10,000,000 Hz for a measuring period of 1 second. Then it was aligned for an overflow to (1)0,000,000.0 Hz (representing 10,000,000.0 Hz) using a measuring period of 10 seconds. Using this test setup and applying a VOM to TP2, the following performance measurements were made:

1) The frequency counter displayed no other values than (1)0,000,000.0 (overflow) or 9,999,999.9 during more than one hour of measurement and for consecutive measuring intervals of 10 seconds at room temperature.

2) No other values than (1)0,000,000.0 (overflow) or 9,999,999.9 were displayed for intermittent shorts of the 10-MHz output terminal to ground. Also, the error voltage of 3.2 volts at TP2 remained constant in this case.

3) No other values than (1)0,000,000.0 (overflow) or

9,999,999.9 were displayed for ambient temperatures of 3° C (refrigerator) or 50° C (stove). No significant change of the error voltage at TP2 was noticed. (The measurements were made quickly after the 1-hour cooling/heating procedure outside the refrigerator/stove since their metal cabinets prevented the circuit from receiving the AM-broadcast station.)

4) No other values than (1)0,000,000.0 (overflow) or 9,999,999.9 were displayed for a change of V_{in} in steps of 10 volts in the range of 7-27 volts.

5) If the circuit is operated employing the European raster of AM-broadcast frequencies, phase modulation of the 10-MHz signal may be expected due to the quasi-periodic/aperiodic operation of the divide-by-1.111··· module. However, due to the long time constant of the low-pass filter following the output of the frequency/phase detector, ac components of the error voltage are filtered out to a large degree and a low phase modulation of less than 4% peak-to-peak was measured with an oscilloscope.

6) The output frequency settled to a display of (1)0,000,000.0 (overflow) or 9,999,999.9 within 60 seconds after power was applied to the circuit.

7) The circuit is sensitive to heavy line noise which in severe cases requires additional line filtering in front of the power supply. It also is sensitive to major disturbances of the AM signal. For example, during a thunderstorm the frequency of the 10-MHz output signal dropped by some Hz several times but recovered within a few seconds. A complete loss of the AM signal causes a drop of the output frequency to the lower bound of the phase-locked-loop capture range on the order of 100 Hz below 10 MHz.

Conclusions

As it was considered unlikely that during the performance tests variations of the output frequency of the circuit were counterbalanced by identical errors of different sign of the frequency counter, the following conclusions were drawn:

- The circuit can provide a 10-MHz reference frequency with a short-term stability of at least 0.01 ppm and a much higher long-term stability.
- Its accuracy and stability are directly dependent upon the quality of the AM-broadcast signal used as a reference frequency. Most AM-station frequencies are accurate to this and even to a higher degree.
- In contrast to a vxo in a thermostat, the circuit needs no warm-up period, it has no drift due to aging, it provides at least one order of magnitude better stability, and it does not cost more.
- It also has all the provisions necessary to accommodate a 9-kHz raster of broadcast frequencies if the FCC should go along this way in the future.

Use the circuit as an external reference, install it as the main clock in the existing space of your frequency counter, or use it as a calibration standard for your station. In every case, you are bringing a degree of frequency accuracy and stability to your ham shack which is maintained for you by other people day and night and brought to your home free of charge. Enjoy it! ■

MICROLOG AIR-1

SPECIFICATIONS

INPUTS: Receiver audio, in & out phono jacks for easy speaker connections. Hand key input allows code practice that reads your sending and drives the transmitter keying outputs.

OUTPUTS TO TRANSCEIVER: Positive and negative switching for CW & FSK keying, solid state or tube type transmitters, AFSK tones at microphone compatible levels, T/R(PTT) transmitter control.

PRINTER OUTPUT: Uses standard VIC printer for "Hard-Copy" of both receive and transmit data regardless of on-the-air mode. Also has hi voltage transistor switch on board for driving current-loop type printers.

DISC & TAPE INTERFACE: Uses standard VIC DISC & DATASET for recording off the air and making long "brag tapes." Another handy feature is the ability to save and re-load your "here-is" memories easily. Since this function is also compatible with your VIC disc drive, it's especially nice for quick start-up.

VARIABLE MEMORY UTILIZATION: A unique Micrology feature allows you to select the size of your text buffer and 8 "HERE-IS" messages from the available computer RAM. It automatically takes into account any memory expansion cartridges you've added. The unexpanded VIC has about 3000 characters for you to allocate. You could for example choose eight 300 character messages and a 600 character text buffer. If you don't tell it otherwise, the system will default to eight 100 character "HERE-IS" memories and a 2200 character text buffer. The expanded VIC will have different default memory sizes, depending on the amount of added memory. The programmable "HERE-IS" memories can be loaded or inserted into the text buffer for transmission at any time.

TEXT BUFFER: Allows you to type ahead while receiving. Text entered into the buffer is visible above the split-screen line for correction before sending.

AUTO-START: Inhibits the display of non-RTTY data.

TUNING INDICATORS: On screen visual tuning aid and audio (pitch) reference tone for RTTY and CW. (Audio is heard thru your tv or monitor's sound channel, just like any other VIC generated audio.)

W R U (Who Are You?): Automatically responds with your call sign when a user programmable sequence up to 15 characters is received.

SEL-CALS: Two 15 character user programmable sequences. Receipt of selcal #1 enables the printer, disc or tape. Receipt of #2 disables these outputs for unattended message store (mailbox).

FULL SPEED OPERATION: Transmit and receive Morse — 5 to 199 WPM, Baudot — 60, 66, 75, 100, 132 WPM, ASCII — 100 & 300 baud.

MORSE SPEED TRACKING: Automatic and speed lock modes, keyboard selectable.

VIDEO DISPLAY: Color keyed display makes optimum use of the computer's color capability. Uses standard VIC format of 23 lines of 22 characters.

SPLIT-SCREEN: Displays text buffer input above and receive/real-time transmit text below the split line.

TOP LINE DISPLAY: Constant display of Time, Mode, Speed/Code in use, and status indicators.

TEST MESSAGES: Quick brown fox and RYRY's in Baudot, U*U* in ASCII, and VVV in Morse.

SPECIAL SYNC-LOCK MODE: Allows improved ASCII operation and "Paced Output" in Baudot RTTY.

T/R(PTT): Fully automatic control of your XMTR via the Push-to Talk line in both RTTY and Morse.

UN-SHIFT on SPACE: Automatically shifts back to "LETTERS" upon receipt or transmission of a Baudot space. Keyboard command on/off.

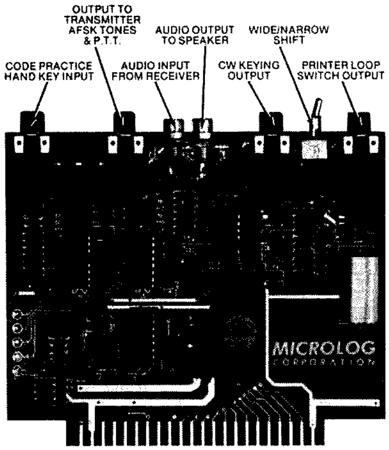
SYNC: Transmits "Blank Fill" in RTTY and BT in Morse when the text buffer is empty and unit is in transmit. Keyboard command on/off.

OUTPUT MODES: CHAR — outputs each character as typed. WORD — outputs full word when spacebar is typed. LINE — outputs full line when carriage return is typed. BUFFER — outputs full buffer, on command.

REAL-TIME CLOCK: Uses the VIC's internal clock for constant on screen display of time which can be inserted into text buffer on keyboard command.

WORD WRAP AROUND: Prevents splitting words at the end of a line. Works in receive as well as transmit.

MORSE TONE DETECTOR: Single tone, 800 Hz center frequency, with effective bandwidth of 300 Hz. Pitch reference regenerated audio tone for easy tuning.



RTTY DEMODULATOR: True dual tone computer enhanced demodulator circuit on standard 2125/2295 Hz tone pair compatible with HF RTTY and VHF FM operation. Switch selected wide and narrow shift.

CODE PRACTICE: Random five character code group generator sends at any speed you set via the keyboard. Hand key input for sending practice and manual morse transmission.

CW ID & NORMAL ID: Two independent 16 character memories for either 2 calls or one normal and one with auto-CW ID for RTTY.

MECHANICAL: Printed circuit board is G-10 epoxy, double sided with plated thru holes. Board is solder masked and silk-screened with parts locations for easy troubleshooting. Size is 5¾" wide by 4½" deep by ¾" high. Fits directly into VIC expansion port and is compatible with popular expander boards in use.

NO EXTERNAL POWER REQUIRED: Unit is completely powered by host computer, eliminating the need for outboard power supply. (Entire system; VIC, Microlog AIR-1, & video monitor can easily run from 12 VDC power for remote or emergency battery operation.)

CONNECTIONS: All inputs/outputs are convenient ¼" 3 circuit phone or RCA phono types. Mating plugs are all provided.

Note: VIC, VIC-20 and DATASET are trademarks of Commodore Electronics, Ltd.

Build the Billboard Keyboard Keyer

Get perfectly-timed CW without a buffer. Then join the crowd at 60+ wpm.

Amid a flurry of activity to make modern amateur radio equipment extremely sophisticated, there are some indications of a welcome trend in the opposite direction. This is evidenced by the popularity of direct conversion receivers, low-power transmitters, and, in some instances, keyers. Magazine editors are begging for manuscripts describing equipment the average amateur can build without a laboratory full of expensive test gear or an engineering degree in solid-state physics.

One area which has not felt the full impact of this simple design philosophy has been that of the keyboard keyer. Some attempt has been made in this direction, but it has fallen far short of most people's expectations.

One early example of a rather uncomplicated device appeared in CQ a few years ago.[1] Unfortunately, there was a flaw in the design which would have rendered the unit inoperable had the builder not seen a following article describing an add-on memory which was published in a subsequent issue of the same magazine.[2] The same author more recently described a fairly simple keyboard keyer which appears to have whetted the appetite of many home-brew artists, judging from the number of units heard on the air recently.[3] Even so, this most recent design requires some fourteen integrated circuits which would intimidate the less experienced builder in most cases.

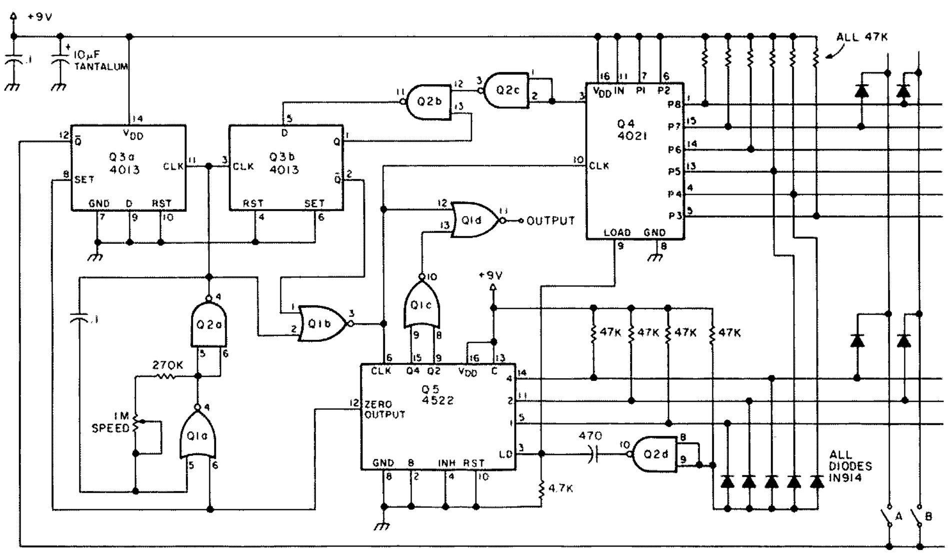

Fig. 1. Schematic of the "Billboard" keyboard keyer. Integrated circuit Q1 is a CD4001B and Q2 is a CD4011B. Although not shown on the schematic, pins 14 of these chips should be connected to +9 volts and pins 7 should be grounded.

Described here is a keyboard keyer which requires only five commonly available CMOS integrated circuits. It is capable of generating all letters, numbers, punctuation, and special characters such as $\overline{AR}$, $\overline{BT}$, $\overline{SK}$, and $\overline{AS}$. The keys are electronically disabled during character generation, which eliminates disrupting that character once it has been initiated. Further-

more, automatic letter spacing has been built into the design so that sending machine-perfect CW is no longer a rich man's game.

The last two features, keyboard lock-out and automatic letter spacing, are extremely important considerations when you give some thought as to how they are used. Take the combination "CQ" as an example. The operator momentarily depresses the "C" key and that character begins. He may then immediately depress the "Q" key and hold it down until the letter "C" and the space following it have been completed. Then and only then will the letter "Q" begin, at which time the operator releases the key and a perfect "CQ" will be generated. With very little practice, this method can be used for all words transmitted, thus reducing or eliminating altogether the need for expensive and complicated buffer memories.

It is my opinion that buffers do nothing more than compensate for poor typing ability in much the same way some operators use linear amplifiers to compensate for poor operating practices. If you are loud enough, somebody will surely answer you. If the operator is willing to practice for a bit with a bufferless keyboard, it is quite easy to fool other keyboarders into believing you actually do have such a buffer installed. Enough said.

Finally, no provisions for automatic word spacing have been included, as it was not felt necessary. Most operators can simulate near-perfect word spacing by ear. Again, this results in a meaningful reduction in cost and complexity.

Design Philosophy

Simplicity by itself is worthless unless consideration to reliability has been given. We have all seen the deceptively simple design which works poorly or not at all. The author was determined that this device not fall into that category. For that reason, schematics and parts lists were circulated to selected amateurs who represented a cross-section of building abilities and experience. Each was encouraged to build his keyboard as he saw fit. In each case, performance was identical to that of the two originals I built. A defective capacitor caused one unit to operate erratically until the culprit was found and relegated to the garbage can. Another builder used integrated circuits of dubious heritage and experienced some problems when operating in high ambient temperatures. Barring this sort of trouble, others building this keyboard keyer should have absolutely no difficulty in getting it to work, perfectly, the first time.

Circuit Operation

A diode matrix is used to encode the keyswitches to information which the electronic circuitry needs to form Morse code characters. Some designers prefer to use toroid transformers for this purpose. It is a moot question as to which method is superior as both have advantages as well as disadvantages. Diodes were chosen here mainly for the high degree of reliability they afford. They are widely available and inexpensive as well.

Integrated circuit Q4 is a parallel in/serial out shift register. Its output (Q8) is used to control Q2C, Q2B, and Q3B which comprise a dash generator. Any time a logic zero is present at pins 1 and 2 of Q2C, a dash will be generated. Otherwise, only dots will be formed. Logic zeros are programmed into the shift register by placing a diode on the appropriate input line and strobing pin 9 (load) high. As the clock input of the shift register (pin 10) is pulsed, any logic zero programmed will eventually work its way to the output and cause a dash to be sent.

Integrated circuit Q5 is a programmable downcounter. It is preloaded to one number higher than dots or dashes in the appropriate Morse character. The purpose of this is to keep the keyed clock (Q1A and Q2A) running for the additional time necessary to complete the automatic letter spacing. The counter is preloaded in identical fashion to the shift register.

Gate Q1C enables the output gate, Q1D, in all cases except when the counter has reached the number one or zero so that the letter space will not appear as a code element.

The other half of the dual-D flip-flop, Q3A, per-

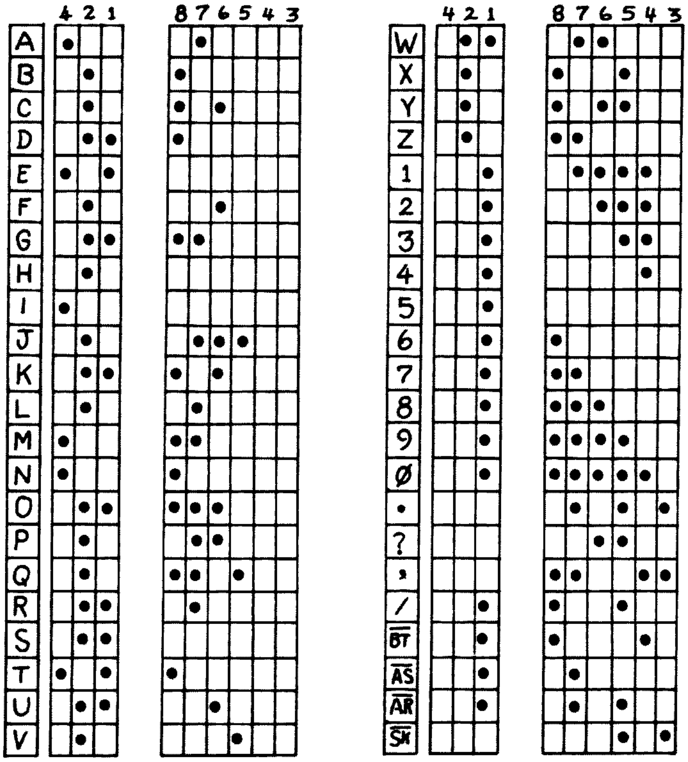

Fig. 2. Placement guide for diodes in the diode matrix. The first column refers to the CD5422 down-counter. The second column is for the CD4021 shift register. A dot indicates that a diode is to be placed in the appropriate line. All diodes are silicon switching types such as 1N914s or 1N4148s. The use of germanium diodes such as 1N34s is not recommended.

forms the keyboard lockout function by presenting a logic one to the common terminal of all keyswitches during character generation. Only after a character and its space are completed will the $\overline{Q}$ output go low, allowing another character to be started.

All this may seem rather complicated at first, but a couple of trips through the logic should bring everything together in short order. Consider each section separately instead of trying to visualize the action simultaneously. There are a lot of things going on at the same time, which may tend to confuse the reader who tries to understand the circuit as a single unit.

It can be seen from the schematic that everything is used. That is, there are no unused gates laying around doing nothing, no flip-flops standing idle. Nothing is wasted, which is one reason this kind of performance can be had with only five active devices.

The addition of a sidetone generator is left up to the individual builder. Most modern transceivers already have them built in. On the other hand, it is useful to have some method of monitoring your progress as you practice sending without the rig being activated. In my latest version, a Radio Shack Piezo Buzzer (part #273-060) was driven by a 2N2222A-type transistor and served the function of a sidetone generator simply and inexpensively. The singular drawback to this device is that the pitch is rather high for this application. Alternately, a 555 timer wired as an audio oscillator could be driven by a transistor in a similar manner to the Radio Shack device. Whatever method you choose, remember, the driving capability of CMOS integrated circuits is limited to extremely high impedance loads. Consult the *CMOS Cookbook* by Lancaster for additional information.

Transmitter keying is best done with a transistor instead of a reed relay to reduce the overall current drain. Since the entire keyer is capable of operating for extended periods of time from a single nine-volt transistor radio battery, it would be a shame to throw this feature away in order to use a relay. My rig is all solid state and requires keying a positive voltage to ground. Again, the 2N2222A was brought into play and performs the task well. For those rigs which require keying a high negative voltage to ground, something similar to the circuit used in the CMOS version of the Accu-Keyer should do well.[4] A recent paragraph in *QST* described a system which is designed to key both kinds of rigs without worrying about switching and could probably be adapted to this keyboard with little effort.[5] In any event, considerations should again be given to the limited current-driving capabilities of CMOS integrated circuits.

Construction

Due to the simplicity of the design, it was decided that no printed circuit board layout was necessary. Instead, the prototype models were constructed on perfboard using point-to-point wiring. This method has proven most satisfactory in this and other projects I have designed. One local builder used wire-wrap, which also worked out well although it was slightly more expensive.

Sockets were used for the integrated circuits to aid the builder should troubleshooting become necessary. The small additional cost is usually well justified, as many years of building experience has borne out.

The diode matrix is easily wired by running "lines" of number eighteen bare copper wire horizontally on one side of the board and vertically on the other. The author terminated the vertical wires with miniature flea clips purchased from the local Radio Shack store. Wires from the individual keyswitches were then soldered to the clips, resulting in a neat and orderly package.

Some number eighteen wire may tend to be springy and difficult to handle as it comes off the spool. By placing one end in a vise and pulling on the other end, the wire may be stretched slightly which will cause it to go limp and perfectly straight. Try this trick and you will be pleased with how well it works.

My unit was housed in a cast-off computer keyboard enclosure garnered at the local surplus emporium for a cost of under five dollars. An earlier version was built into a home-brew box which was not very attractive but quite functional. It is difficult to justify putting a twenty-dollar circuit into a twenty-five-dollar box with my limited budget. If that sort of thing doesn't bother you, there are some very nice commercial enclosures available. Just remember to make it metal for shielding the circuit from strong rf fields.

The actual keyswitches were purchased from Jameco Electronics of Belmont, California. They come as a unit molded into a plastic base thirteen inches long. Because I had need for only forty-four keys instead of the sixty-three supplied, the unit was cut down to ten and one-half inches long prior to wiring. This modification allowed space inside the enclosure for additional circuitry which will be described in a subsequent article.

As with any project, the finished unit is only as good as the parts which go into it. Cutting corners usually results in compromised operation. If a silver mica capacitor is specified, use one. The same applies to tantalum capacitors. They were chosen for a reason. Also, wherever possible, use "B" series integrated circuits as they are more reliable and better suited for this application. The erratic operation in high ambient temperature environments discussed earlier was cured by switching from "A" series to "B" series chips from a reliable vendor. Nine-volt transistor radio batteries are ideal power sources for CMOS designs. However, one should take care to get a quality unit. Don't waste your money on the dimestore cheapies. Don't rob the one out of the kid's handie-talkie. Buy a fresh alkaline cell for best results. It is money well spent.

If there is a keyboard keyer in your future but the family budget won't allow the several hundred dollars a commercial job requires, consider rolling your own. You will be the winner all the way around in dollars saved and pride of using a piece of equipment you built yourself. As an added bonus, most keyboarders find their code speed increasing steadily and rapidly. Perhaps the "Billboard" described here is the key to an Extra class license for you. ■

Construct the Lead-Foot Key

If you like your CW in the fast lane, you'll love this key. And it is guaranteed not to slip—at any speed.

Editor's Note: Melting lead can be dangerous! Not only can you get burned, but the fumes can be toxic, too. Use caution and plenty of ventilation.

J. H. Owens W5JQE
Rte. 1, Box 218-T
Pottsboro TX 75076

Have you ever considered building your own keying-paddle, only to be stopped short by lack of a heavy metal base? Me, too. Then, one day after eating some sardines, I was about to throw the can away, when I took a second look and got a great idea. Why not fill the sardine can with melted lead and use it for the base?

Thinking about it for a while, I could find no flaws, so I scrounged some used automobile tire-balancing weights and melted them into the can with my propane torch. The metal clamps floated to the surface where I picked them off with pliers. The sludge also floated to the surface, and I scraped it off with the lid from the can. (A friend of mine used lead pipe and melted it in the can over a kitchen range burner. But, before that, he drilled a hole in each end of the can, and put a sheet metal screw through it, this to hold the lead casting and the can securely together.) So far, so good.

After the lead-filled can cooled down, I washed off the traces of sardine oil with solvent (you can use lantern fuel, paint thinner, acetone, etc.), then roughed the surface with fine sandpaper, and gave it a coat of paint. Not bad. The upside-down can was smooth and nicely contoured. Heavy too... it weighed four pounds.

A little later on, I found that it was also very adaptable for mounting the keying hardware. All I had to do was drill pilot holes through the can and into the lead casting—*very slowly*. If you don't have a hand-drill or variable-speed electric drill, use your regular electric drill, but turn it on and off repeatedly to keep it from running fast. I used a #4 drill, 3/32" in diameter, and kept it oiled. Now I was able to mount the parts with #6 × 1/4" sheet-metal hex-head screws. Neat.

The Paddle Arm

The biggest challenge I found in making the paddle arm was finding the right material. I went through the usual list of leaf switches, hacksaw blades, etc., only to find out that those

The finished model with glass-epoxy paddle arms, which give it a "hard" feel, like the commercial paddles. Phenolic arms are more flexible and give it a "soft" feel. If you like a really soft feel, make the arms an inch longer. Hey! If you don't like sardines, you can get smoked clams or oysters in the same size can!

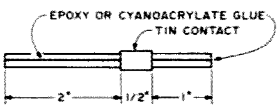

Fig. 1. Paddle construction. Clamp glued ends together until cement has cured. Use same technique for tin-plate ground contact.

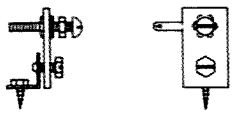

Fig. 2. Keying stanchions. To begin, gap the points at 0.010".

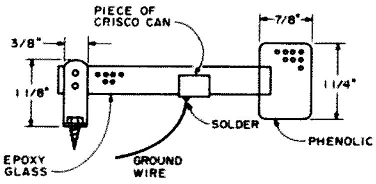

Fig. 3. Details of paddle-arm assembly.

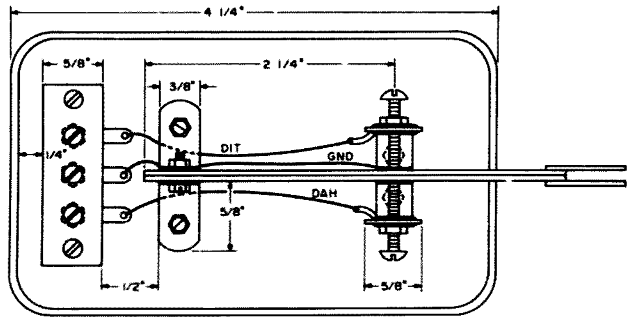

Fig. 4. Top view of the completed key. The dimensions were measured on one of the models, but need not be exact.

springy gadgets have *minds of their* own! They keep on bounding back and forth after you want them to stop, and good electrical contacts they ain't. So, after many trial-and-error experiences, I got down to some basic reasoning.

What I really needed was a lightweight material, having low mechanical Q, or high damping factor, something rigid in one plane and flexible in the other. But what? Then it hit me. How about a strip of perfboard or, better still, *two* pieces? After some experimenting, I ended up with two strips of 3/64" (0.0468) glass-epoxy board, about 5/8" wide and 3½" long, glued together at the last half-inch on each end with epoxy cement. You also can use cyanoacrylate cement. See Fig. 1.

This assembly provided the desired damping factor, and more. Let me explain. When you bend the arm, one of the perfboard pieces is *stretched* and the other one is *compressed*, and the friction between the two absorbs the stored kinetic energy quickly. If you want to test this, clamp one end in a vise, and flick the other end with a finger. Listen closely, and note the time it takes for the vibration to stop. Now try this same test with a hacksaw blade and you will find that the vibrations last *ten* times as long. No minor difference here, but a major improvement. OK?

The Dit-Dah Electrical Contacts

Still another challenge was finding a satisfactory substitute for the precious-metal contacts used on the finer commercial models. No big problem with the stanchion contacts—6-32 nickel-plated brass screws, about one inch long, worked OK. I made the stanchions by cutting a terminal-strip into two pieces, and mounting them to the base with half-inch angle brackets. See Fig. 2.

The common, or ground contact, on the paddle arm was a little trickier. The best thing I could find was shiny tin-plate, such as used for Crisco and other hydrogenated vegetable-oil cans. S-o-o-o, I raided the refrigerator and transferred the cooking grease from its container into a plastic storage box. Then I cut off a piece of the can material about a half inch wide and an inch long, cleaned all the grease off it, bent it around the paddle arm, and glued it in place. See Figs. 3 and 4.

Next, I soldered the flexible ground wire to the bend point. Finally, I sprayed the contact surface for lubrication and corrosion resistance . . . WD-40 or TV tuner spray works well. Voilà! Soft-touch contacts. Not gold, but so much *much* better than blued steel.

The Non-Slip Feet

One thing I hadn't planned on was a 4-pound paddle slipping around on my operating desk, even with rubber feet on it. I talked with some other hams and they told me that they had the same problem with their bugs and paddles. Some glued them to their desks, others drilled holes and screwed them down.

Well, I kept trying different things until one day I hit the jackpot with polyurethane foam. This is the stuff used for cushioning fragile items for mailing. It also is used as weatherstripping tapes. It worked, beautifully. Dime-size pieces, about one-quarter inch thick, glued to the lead base, did the job. The final choice was two strips, about a half inch wide, glued with rubber cement along each underside of the base. This stuff works on the commercial paddles, too. Just slip a little piece under each one of the rubber feet to make contact with the desk surface. I know, because I own one of those commercially-built paddles, a fine piece of precision machinery.

So, why did I go through all of this work to build a paddle? Well, the problem is that the manufactured paddle is *iambic*, and I am *non-iambic*. That's incompatibility. I just couldn't avoid closing both the dit and dah contacts at the same time, too often in the wrong order. Mistakes, mistakes, mistakes. So, I decided that the "squeeze" system, as well as the squeeze paddles, were not for me. Unfortunately, I could find no non-squeeze, non-iambic paddle on the market. So, I built my own. Maybe this article will stimulate some manufacturer to take a step *backward*. Anything to cut down on the keying mistakes on the air would be a blessing.■

Hardware for the key. The contact stanchions were made from a second terminal board (same as the one on the left) cut into two pieces. The angle brackets for the contact stanchions shown had pierced-and-threaded holes, but their base ends had to be cut off to leave only one hole. Ordinary 1/2" × 1/2" angle brackets would serve as well. The sink-faucet washers may be glued to the base to raise it higher if desired. The sheet metal screws for the terminal board have to be 1/2" to 5/8" long to account for the standoff spacers.

The $2 Infinite-Memory Keyer

Take a break. Your cassette recorder will send any message for you.

If you have a cassette tape recorder and like to operate CW, you can add an infinite memory keyer to your station for about two dollars. The idea is to place your CW messages on cassette tapes and play them back to key your transmitter. The demodulator presented in this article will convert the CW tones from the tape player into keying signals to drive the transmitter.

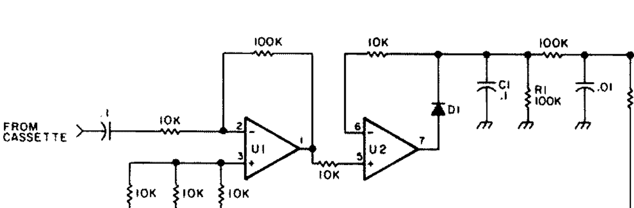

Fig. 1. Cassette memory keyer block diagram.

For repetitive messages such as CQ CQ DE . . ., you can use a continuous cassette tape. These come in 1/2-, 1-, 2-, and 3-minute durations. The tape in the cassette is looped back on itself and thereby forms a continuous tape. For code practice or message broadcasts, the usual C15, C30, or C60 cassettes could be used.

Code can be placed on a cassette by using an audio oscillator or your transmitter sidetone. Best results are obtained if the code is transmitted directly from the oscillator circuit to the mike input of the cassette tape recorder rather than recorded by microphone pickup. Too much background noise results from the latter.

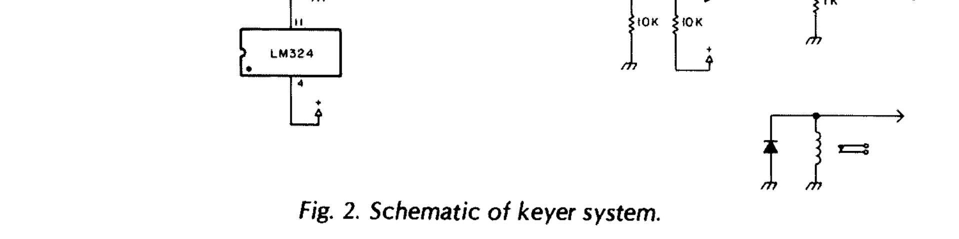

Fig. 2. Schematic of keyer system.

Demodulation

Before presenting the cassette keyer, let's look at the general demodulation process. As shown in Fig. 1, it consists of four steps: limiting, peak detecting, low-pass filtering, and slicing. The limiter is used to amplify the cassette CW tones and to provide sufficient drive for the peak detector. Also, the limiter will smooth out any small variations in the amplitude of the tones. This process is similar to FM detection ex-

cept that the filter or discriminator is discarded.

The peak detector is set to convert the limited tones to positive-going pulses. It acts as a half-wave rectifier but retains the positive peaks for a short duration; hence, the pulses have a slight ripple pattern at their tops. The circuit ignores the negative-going portions of the tones.

The low-pass filter is then added to remove these ripples. The system will work without the filter as long as input tones are clean and strong. It aids operation, however, when tape output is marginal.

The slicer converts the peak-detected pulses into TTL-compatible signals that go from 0 volts in the off state to about 3.5 volts in the on state.

Circuit Schematic

Now, let's examine the circuit schematic, Fig. 2. All of the signal processing is done with a single operational amplifier chip, an LM324, which contains four separate op amps. The circuit can be operated from a 5- or 9-volt dc supply. All resistors are 1k, 10k, or 100k, with the exception of one 470-Ohm resistor.

Circuit Operation

Cassette tones enter at the left and the TTL-compatible output is at bottom right. The circuit can also drive a low-voltage relay if it is substituted in place of the 1k output resistor at pin 14.

The limiter, U1, has a gain of ten and is biased at pin 3 to one-third of the supply voltage. This bias also sets the dc voltage level at pins 1, 5, 6, 10, and 12.

The peak detector, U2, charges capacitor C1 to the peak voltage of the tones that appear at pin 5. When the voltage at pin 5 exceeds the voltage on C1 and hence also at pin 6, U2 forward biases diode D1 and further charges C1. When the voltage at pin 5 drops, U2 turns off and C1 holds its charge until the bleeder resistor, R1, discharges it. C1 and R1 are set so that the ripple at C1 is small but the pulse formed from the code signals follows the code quickly; this is always a compromise.

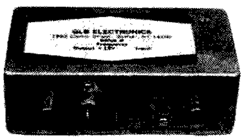
The ripple is then removed by the RC low-pass filter. It does a sufficient job and frees up the fourth op amp in the LM324 IC to be used as a tuning indicator.

U3 and U4 work as slicers, or comparators, and convert the pulses from the peak detector into TTL-compatible signals. A dc restore circuit could be used here as an alternative. The advantages of the slicer are that it cleans up some ripple that may still remain and generates sharp and clean rise and fall edges for the keying output. The bias for U3 and U4 is set about one volt above the bias for U1 and U2. Therefore, when a pulse is generated at U2, the voltage crosses over the bias voltage of U3 and U4, generating positive pulses at their outputs. That is, when the voltage at pin 12 exceeds the bias voltage at pin 13, pin 14 will have an output nearly equal to the supply voltage.

The output of U3 is used to drive an LED indicator. This makes tuning and circuit verification of proper operation easy. The circuit as a whole could be used for receiver CW demodulation if a CW filter is placed between U1 and U2. You may want to consider that when planning circuit construction. Happy cassette keying! ■

GLB HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in **AMATEUR** and **COMMERCIAL** systems.



COMPARE OUR CURVES!

Typical rejection:
± 600 Khz @ 144 Mhz: - 28dB
± 1.6 Mhz @ 220 Mhz: - 40dB
± 5 Mhz @ 450 Mhz: - 50dB

- 40 to 1000 Mhz - tuned to your frequency
- 5 large helical resonators
- Low noise - High overload resistance
- 8 dB gain - ultimate rejection > 80 dB
- 10 to 15 volts DC operation
- Size - 1.6 x 2.6 x 4.75" exc. connectors
- **FANTASTIC REJECTION!**

Price - $79.95 bipolar w/RCA jacks
Connector options: BNC $5, UHF $6, N $10

SUPER HOT! GaAs Fet option $20

We offer a complete line of transmitter and receiver strips and synthesizers for amateur and commercial use.

Apple, Morse, and You

Simple software and cheap hardware make for a great CW keyboard recipe. Just add one operator.

Have you been looking for a CW keyboard program in BASIC for your Apple II computer with Applesoft? The program provided here will enable you to use the Apple as a CW keyboard with sidetone and speeds adjustable from around 5 words per minute to about 70. The program is easily modified to provide for any special characters you might wish to have.

Lines 1000 to 1460 contain the Morse data. The data lines consist of the ASCII value for the character followed by a Morse representation. A 3 signifies a dash, a 1 stands for a dot, and a 0 marks a space. For example, line #1110 says the following:

1110 DATA 65,130

The number 65 is the ASCII code for an uppercase A. The 130 means didah, followed by a short space to keep it from running into the next letter.

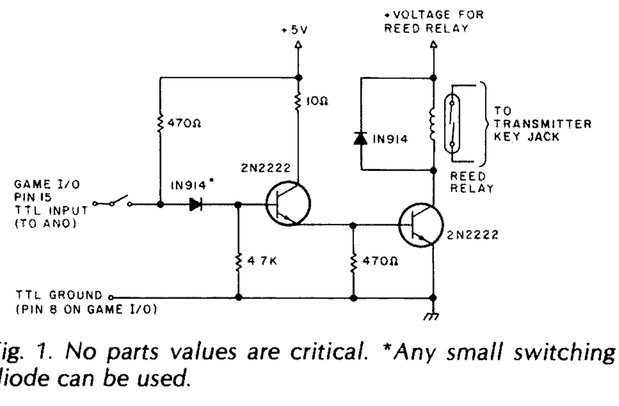

*Fig. 1. No parts values are critical. *Any small switching diode can be used.*

When the program is run, the computer will take the data listed between lines 1000 to 1460 and load it into the string matrix CODE$. The location within CODE$ is the ASCII value of the character; in other words, location 65 in CODE$ contains the data for the Morse letter A. When characters are sent to the computer from the keyboard, the computer changes the letters to their ASCII value (using the BASIC ASC($) command) and looks in CODE$ (<ASCII value of letter>) for the Morse data. The Morse data is then dissected character for character using the BASIC MID$(X$,X,X) command.

Lines 80 to 90 are for the CW sidetone. These lines POKE a machine language subroutine which will enable the Apple to send the CW through the internal speaker. The value POKEd into decimal location 768 on line 70 determines the pitch of the sidetone.

Line 130 gets a single character input from the keyboard. This character is then checked to see if it is a control character used for a special purpose on lines 140 to 160. In this program, the control characters A, B, Y, and Z are used for special functions.

The subroutine at line 200 is what takes the Morse data from the proper location in CODE$ and generates the Morse signal from it. The Morse character can be heard on the Apple speaker. Also, the annunciator TTL output number 0 will be toggled on and off in Morse code. This signal

can be used to drive your transmitter through a suitable driving circuit. The circuit used must take the TTL output and use it to drive a reed relay which, in turn, keys the transmitter. An example of such a circuit is shown in Fig. 1. The lines which turn AN0 on and off are located at line 235 and line 245. Line 240 is a call to the machine language sidetone routine.

Using the program is a simple procedure. When the program is run, the screen will clear and the following will appear:

MESSAGE—>

After this prompt, type in a message for the memory. This message can be played back at any time while in the keyboard mode of operation by simply pressing either CTRL A or CTRL B. The message may be up to 254 characters in length. If the message contains commas, enclose it in quotes.

The next thing to appear on the screen is:

SPEED

Type in a number between 1 and 85. Note that 85 is the *slowest* speed. The fastest usable speed is about 6. At speeds faster than this, the transmitter does not key accurately. When set for a speed of 7, the code speed as measured on a Kantronics Field Day II code reader was in excess of 75 words per minute.

After the above two items are entered in, the program will operate as a CW keyboard. When a letter is typed on the keyboard, it is sent through the speaker and AN0 in Morse code and displayed on the monitor. If you want to play back the pre-programmed message, hit control A or B. To reset the speed, use CTRL Z. If you want to change the message, hit the CTRL Y keys.

I gave the following keys special functions: ESC produces the Morse error code (eight dits), and the colon (:) is the CQ key. To add a special function to any key of your choice, all you must do is determine the ASCII value of the character and put it on a DATA line followed by the Morse representation of what you want sent. For example, if your name were Joe and you wanted the computer to send your name whenever CTRL N was pressed, you would add the following line:

DATA 19, 1333003330010

The line number can be any unused one, as long as it comes before the end of data marker at line 1460.

Because of the structure of this program, it is quite easy to make some useful changes. One thing that would be quite easy to implement would be to have the program output American Morse instead of International Morse. To get the longer dashes used in Continental code, use a 4 or a 5 instead of a 3 for the dash character. This will limit the top speed number that can be entered in to a 51. It also would be necessary to change the *end* of line 50 to read:

IF S * 5>255 THEN 50

*****NEW*****
FOR THE TRS-80*
COLOR COMPUTER
MORSE CODE

Here's a way to turn your Color Computer into a complete CW Morse Code terminal.

—**KA9FSQ CW MODEM** Interfaces the computer to your transceiver via the ROM-PAC slot.
Cartridge: $50.00

—Three CW programs to choose from.

—**KA9FSQ TRANSLATOR** (Machine language)
TX programmable from 5-60 WPM, RX to 60 WPM. Features split screen operation, a 255 character keyboard buffer, and automatic CQ using your own call letters.
Cassette: $24.95

—**W9AV TRANSLATOR** (Extended Color Basic)
TX programmable 5-50 WPM, RX to 30 WPM. Includes 9 message memories, and a CW practice mode which sounds over your TV.
Cassette: $14.95

—**W9AV QSO ROBOT** (Extended Color Basic)
TX programmable 5-50 WPM, RX to 30 WPM. Use the keyboard or Auto Mode. Makes complete CW QSO's without human intervention including exchange of calls, RST, QTH, and names. Also keeps a log.
Cassette: $19.95

For additional information & programming, write to:

MITRONIX

Mike Rice KA9FSQ

*Trademark Tandy Corp.

240

This is needed to accommodate the longer dash character.

I hope you will enjoy using this program. If you own a micro other than an Apple II, you can use the same fundamental program as long as your BASIC contains string manipulation functions. The sidetone and keying of the rig will vary greatly on different types of computers. ■

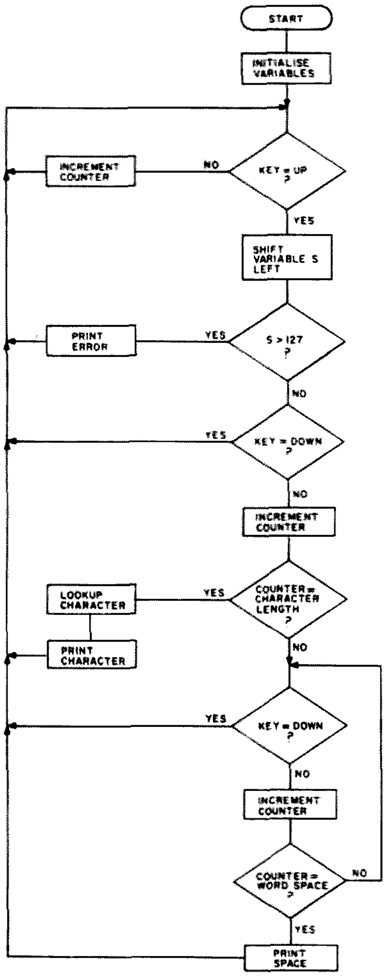
Micro McElroy

Is Pet BASIC fast enough for solid CW copy? You bet—and this program will work miracles with a sloppy fist.



Flowchart.

Mike de la Dette VK3BHM
79 Bedford Road
East Ringwood, Vic. 3135
Australia

Most CW reception programs are written in assembly language to optimize speed and efficiency. This is a good idea, but makes conversion of the program to run on another computer very difficult and time-consuming. Also, while many people are very proficient in high-level languages such as BASIC, not everyone is prepared to devote the time required to program directly in assembly or machine language.

Having written a routine in machine language to decode CW on my Commodore Pet™, it occurred to me to try a direct translation into BASIC. Would it work? Surely BASIC would be too slow and inefficient.

The results were very surprising. The routine is very short (under 500 bytes) and handles speeds of up to about forty words per minute. This limitation on speed is imposed by the BASIC interpreter in the Pet. Higher speeds could be obtained on versions of BASIC which employ a compiler rather than an interpreter. Armed with the BASIC listing and flowchart, anyone reasonably familiar with their machine's assembly-language instruction set should be able to write an equivalent machine-language program, if speeds in excess of 40 wpm are contemplated.

The memory location in my Pet for input/output is at 59471 (decimal). With a key connected between pin L on the user port and ground, the value obtained by PEEKing this location will change from 255 to 127. These values are set in line 5 of the listing. Variables U and D give the values for key UP and key DOWN respectively and variable P contains the input port address. You will need to change these three variables to match your computer's arrangements.

Variables F and T determine the receiving-speed

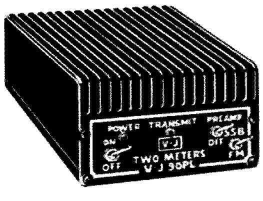
V-J POWER UP

2 METER 90 WATT OUTPUT AMPLIFIER WITH 18 DB GAIN PREAMP

Model 90PL FOR ONLY FACTORY DIRECT

$139.95* PLUS SHIPPING



- FREQUENCY range 144 - 148 MHz
- OPERATION FM or SSB (completely linear) Class AB1
- RF DRIVE 1 to 30 watts
- KEYING RF activated with high quality relays
- SSB operation built in delay
- POWER REQUIREMENTS typical 10 watts drive, 13 amps at 13.8 VDC
- IDLE current 20 mills
- MOBILE or FIXED operation
- PREAMP 18DB gain minimum
- NOISE FIGURE less than 1.5 DB
- PREAMP KEYING independent — separately RF activated relays
- CONSTRUCTION wrap around aluminum heat sink 2 pieces 360 degrees cooling
- SIZE 7"(w) x 6"(d) x 3"(h) — WEIGHT 3 lbs. 9 ozs.
- IMMEDIATE SHIPMENT

SERVING THE ELECTRONICS INDUSTRY SINCE 1965

"window" and are set in line 10. This gives a center speed of approximately 20 wpm on the Pet. As these values will vary according to the execution speed of your computer's BASIC, I have not supplied a conversion constant or table. You will need to experiment with differing values for variable F to obtain a constant which can be divided by the speed required to produce a new value for F. The algorithm used will decode CW over a wide range of speeds without altering these variables, but word spacing will suffer.

If using a hand key or electronic keyer directly into your computer, place a .1-uF capacitor across the key contacts to smooth out the inevitable bounces, especially if using a relay.

After trying things out on local copy, you will need to make up a demodulator to convert your receiver's audio into a signal which switches between ground and +5 volts. A one-IC PLL circuit is a good place to start and will cost very little. If you plan to use a RTTY demodulator, disable the limiter—hard limiting will bring up the background noise to the point at which copy is impossible. Also, you will not be able to use your receiver's CW filter if the demodulator is set up to accept only the standard 2125/2295-Hz RTTY frequencies. This is no great matter, but you will need to set your receiver to a somewhat higher-pitched tone than is usual for CW. Ideally, a separate demodulator with anti-noise circuitry, slow agc, and filtering centered around 1000 Hz should be used.

The algorithm used will cope with odd dot/dash ratios, "swing," and other irregularities. However, like most CW decoding systems, it is easily confused by very poor inter- and intra-character spacing. If the other guy's CQ sounds more like NNMA, then it's time to put your headphones on and switch over to the computer Ted R. McElroy used all those years ago. That's the one with enormous memory, fantastic speed, and incredibly complex I/O; you'll find it right under the headphones! ■

QRP Keyer for Misers

Get machine-perfect code with this keyboard. All it costs is 30 mW and a few dollars.

What on Earth is a QRP keyer? A very reasonable question. If you run a kilowatt, your keyer could draw five Watts, but if you run less than two Watts, you start looking for another keyer: a low-power, or QRP, keyer. Any keyer you have should be consistent with the power of transceiver that you are using. In my case, being a convert to the QRP doctrine, the keyer must be in the very low milliwatt range. Specifically, the following design draws 30 milliwatts and has nearly as many features as it has milliwatts.

Well, now that you are reading about QRP keyers, a word about why a low-power keyer was conceived.

The project was initiated for two reasons: one, to have a keyboard for portable and vacation operation, and the other, to have a good electronic keyer to use for the instruction of a Novice class. My experience with teaching code using a computer and seeing the advantages of properly-sent Morse at known speeds and intervals has confirmed me as a keyboard-keyer user. The problem was not that there were no circuits to do most of the above, but that they each had some good features and some undesirable ones.

In reviewing the more recent articles, several are of note. K1GN[1] describes an excellent keyboard unit which incorporates an instructor function that is capable of sending random five-letter groups with variable delay between characters. However, the method of encoding the Morse character with diodes is not appealing. Also, the lack of any type-ahead buffer would make the sending of Morse for extended periods quite trying.

Steber's[2] Morse-a-Keyer has many more desirable features. It has type-ahead, it has a simple encoding scheme, and it was designed with readily available parts. The major drawback is the use of a 1702A PROM to convert the ASCII to Morse. The ASCII keyboard, the PROM, and its associated negative voltage inverter consume 95% of the power required to run the keyer.

K2BLA's[3] unit offers a good solution to the problem of encoding the Morse characters—a scanned keyboard. However, the limited capability for type-ahead of only two characters is hardly in the realm of a unit for "armchair operation."

After this survey of keyboards, several criteria became apparent for a good portable/instructional keyboard:

- it must be low power
- it must have a type-ahead buffer
- it must have an accurate speed indicator
- the buffer must have a useful indicator of "how full"
- it must be small in size and self-contained
- it should have a store feature for preloading the buffer
- it should have an Escape key to quit operation if break is required
- it should have an indicator for battery condition
- it should have switchable sidetone

With this list of "desirable features," the QRP keyer was attempted and the following was the result.

The Keyboard

The keyboard is a surplus unit with all the electronics removed. (Similar units are advertised in the $20-to-$25 range in this magazine and other amateur journals.) The keys, their mounting frame, and the PC are retained; all excess printed-circuit traces are cut away with a hobby knife and pliers, leaving only the keypads on the PC board.

The push-and-lock switches such as the shift lock and

similar functions were moved to the back row, as these are useful for analog functions which are described later. After all this carving of the PC board was done, the keyboard was rewired with small-gauge wire as outlined in Table 1.

Fig. 1 gives details and references for the following discussions. The keyboard encoder is a 16-by-8 matrix which allows for all of the common Morse characters to be encoded. Additional wiring is required for special characters and functions that are not encoded by the scanned keyboard but are essential just the same. These include Escape, Space, Tune, Speaker, Meter, and Store. The rewired keyboard is interconnected to the electronics card by a 50-conductor cable. I used a length of surplus telephone switchboard cable. (For a description of the operation of a scanned keyboard, see Reference 4, as this is the probable source of most scanned keyboards.) The QRP keyer's design extends the Lancaster keyboard to a 16-by-8 and also makes it a Morse unit rather than ASCII.

Type-Ahead Buffer

A highly desirable feature in a keyer is the type-ahead buffer, providing the ability to type on the keyboard at high speed and have the keyer send at a slower speed. With this capability, the timing of your letters and spaces is not tied to your uneven hunt-and-peck at the keys. The type-ahead in this keyer differs from previous units in that it has a segmented buffer. The 48-character buffer is in three parts, each of which indicates on a meter. While you are typing, the keyer keeps track of how much space has been used with each keystroke. When you are one-third full, the meter will indicate one-third full scale and multiples of one-third up to a full buffer at which time characters will be lost if you keep on typing. The 16-character type-ahead buffer in Reference 2 does not give meaningful indications as it only lights an LED when the buffer is full; you are left to guess whether it was the last key you pressed or one or several before.

I find that with the 48-character buffer there is little problem with overflow of the buffer. In practice, I type on the keyer until the meter indicates two-thirds full and then I finish my sentence and wait until the keyer empties the buffer to one-third or less and start typing again.

The circuit for indicating the fill of the buffer is straightforward. The data-in ready flag on the 40105 FIFO (first-in, first-out memory) indicates whether the particular 16-character segment is full. If it is full, the flag line goes low and this indication is fed via an inverting buffer to a summing network of all three FIFO segments. The summed voltage point of the three FIFOs is fed to a meter. The meter serves a dual purpose since it indicates the condition of the batteries when the switch is moved to the Bat position.

The Keyer

The heart of the keyer is the PISO section (parallel-in, serial-out). The PISO takes the parallel two 4-bit parts of the Morse word from the buffer and sequentially shifts these bits through a

set of four dual flip-flops (ICs 10, 15, 19, 23), testing for dots, dashes, spaces, or whether the last element of the word has been sent. The space character is not, of course, a Morse character, but must be represented by some unique 8-bit word that can be stored in memory like any other character. The space is not generated by the scanned part of the keyboard, but is a jammed character. It is encoded by resetting the scan register (IC2) to all lows and, via gates IC11a and 11b, bits 0 and 3 are set high which in effect generates a space word. The space has its own keyboard strobe circuitry also; it is a part of IC6. (It would have been possible to generate the space character if a larger matrix for the scanned keyboard were used, but the additional logic for the jammed character was less and therefore was used.)

The Wpm Clock

The QRP keyer uses a more complicated clock than previous units. Most common wpm clocks are interconnected gates which rely on RC time constants and are predictably nonlinear. The clockwise rotation of a linear potentiometer to control speed has far too much travel on the slow end and is cramped up on the high-speed end. A log control was tried, but the improvement was not sufficient. I am sure you can remember how important it was to you when you were learning the code that your instructor be able to tell you exactly how fast he was sending. Well, to this end I put a better wpm clock in the QRP keyer.

A voltage-controlled oscillator was used for the wpm timer; this type of oscillator produces a linear scale and has nearly constant duty cycle. There is some slight shift in speed as the batteries age, but with good batteries you can say with some confidence that you know the speed to be over 10 or 15 wpm (or whatever) for a least a year.

Calibration of Wpm

The easiest way to calibrate the wpm clock is to prestore the word PARIS five times with spaces between each and time how long the keyer takes to send the set of words. After timing, apply the formula: code speed (wpm) = 300/T (sec). If, for example, the set takes 15 seconds, your code speed is 20 wpm.

Keying Relay and Sidetone

The relay circuit and the sidetone generator are derived from earlier designs, but a couple of features have been added. The sidetone is now switchable. This allows the sidetone to be silenced when the keyer is used with a transceiver which has built-in sidetone. The sidetone oscillator is turned off at its power connection to conserve power, as the audio section of the keyer draws more than the logic section.

Escape and Store Keys

The Escape key allows you to abort sending if you hear a break or if you want to change that which has already been entered into the buffer. The store function allows you to pre-type into the buffer, but not to send its contents. This is useful when you are just finishing your copy of the other station and you can pre-type in your callsigns while your contact is still sending the required identification.

Physical Layout

The keyer was built into an old but somewhat elegant box which held a tool kit for a chemical instrument. I hope you can be as lucky and find something similar. If not, a small attaché case is ideal both from a size and cost standpoint. A baseplate for the keyer was fabricated from 1/16" aluminum sheet, just big enough to fit inside the case. Photo A shows the whole unit with the cover on. As you can see, the keyboard is not enclosed. It is on spacer blocks (¾") which

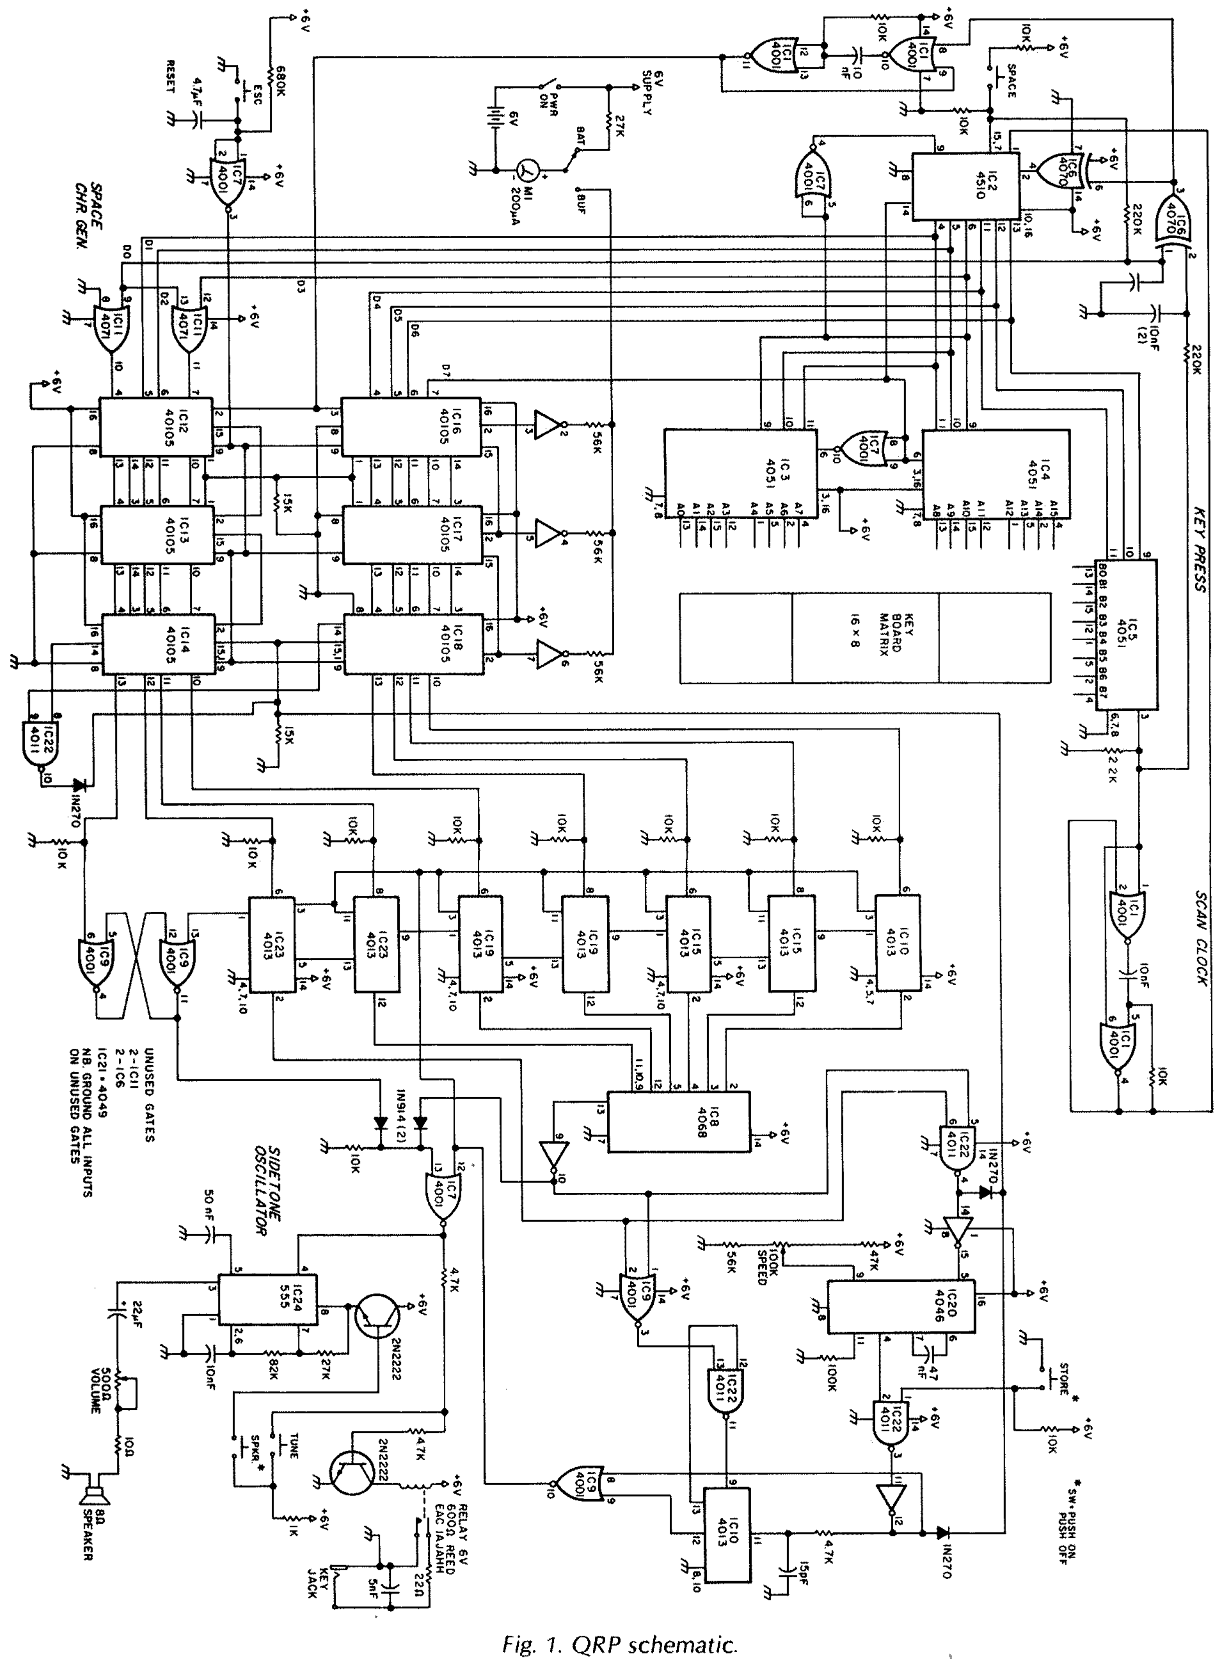

Fig. 1. QRP schematic.

provide sufficient clearance for the PC board on the bottom of the keys and its associated new wiring.

The electronics is in three parts: the main logic board—a 4½" × 6½" 44-pin computer-type card, a small perforated board for the keying relay and sidetone, and the control panel. Photo B shows the logic board and its connections to the keyboard. The small 16-conductor cable which connects together the con-

trol panel, the card, and the sidetone board is on the lower left side of the card. (See Photo C for exact placement.)

Photo C shows the control panel which has the speed control, the power switch, the battery/buffer switch, the volume control, and the miniature key jack. The panel is mounted on small standoffs which allow the speed control to clear the baseplate. As is shown in Photo A, the speed control knob is just level with the top of the panel. (In effect, the panel is in a well cut out of the cover.) Size C batteries were used as space permitted, and annual battery changes are desirable.

Photo D shows the special keytops and the Bat/Buf meter. The meter was mounted on a small plate and fitted to cover the hole for the old keyboard encoder IC which is not now used. The meter's placement is not just cosmetic, but also practical, as you can watch the meter easily while typing, as it is near the space bar.

Keytops

The keytops for the special keys are worth a few words. I have made several other keyboard controllers and was always stuck on how to label the special function keys effectively. I have tried painting the keys and using press-on lettering covered with several coats of lacquer, but this lasts only several months. On this keyer, I tried something which is much better.

The original keys were concave, and after roughing them up with fine sandpaper, a thin "float" of black epoxy was applied. With a little warming with a heat gun (or hair dryer), the epoxy conforms to the shape of a keytop, slightly convex but conforming to the top. After this was completely dry, the keys were labeled with the special functions using white press-on lettering. Next was applied a clear "float" of epoxy on the lettering. After this was set and was lightly sanded to remove any droplets or uneven areas, the tops were polished with a plastic or fine metal polish, and "professional" keytops of specific designations were the result.

As epoxy formulations vary, try the whole procedure on a small scrap of metal to ensure the compatibility of the epoxy and the lettering. I used 5-minute-type epoxy and allowed 24 hours between coats. Another possibility is to use graphite to tint the clear epoxy, but I found that the curing time for the 5-minute type extended to 48 hours due to the inhibiting action of the graphite. If you can wait, you can save some money.

Using the Keyer

When the keyer is first turned on, hit the space bar and then a letter; this initializes the logic. I usually hit an E, as this gives the fastest check that all is well when I hear the dit. If you hit the Escape key to abort sending, repeat the above procedure as this will ensure that you are loading or sending exactly what you intended.

Probably one of the most important things to remember is to send only at a speed you can receive. The temptation will be great to send faster, but just sit back and enjoy the comfort of the keyer sending while you have a sip of coffee. ■

The Easy FIFO Keyboard

First in, first out means you type as fast as you want to. It will send at the speed you set.

Home-brew keyboard designs are now readily available and construction need be no more costly than a regular keyer. However, some home-brew designs, while effective, are limited to the basics of character generation. The operator must provide the proper timing to maintain a certain conversational speed and rhythm. This task can easily be left to the keyboard itself by the addition of a relatively inexpensive buffer memory.

The Fairchild 3341 first-in, first-out (FIFO) is a serial memory that operates in basically the same manner as a shift register. Data is entered, is shifted to the output, and is removed. However, there is an important difference between the two. The conventional shift register will retain data in its first register position until additional data enters the system and forces the previously entered data to the next register position. In the FIFO, data entering the register is immediately shifted to the first open position at the output end. This feature automatically allows buffering between two systems that operate at different data rates. The 3341 is asynchronous in that data input and output are completely independent. The 3341 can also control system speed.

Fig. 1 is a block diagram of the 3341 control logic.

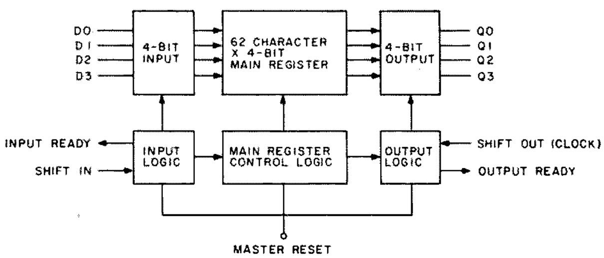

Fig. 1. The Fairchild 3341 MOS FIFO buffer block diagram.

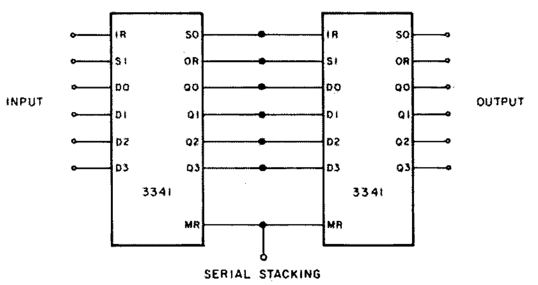

Fig. 2. FIFO serial stacking to expand a buffer memory to 128 or more characters.

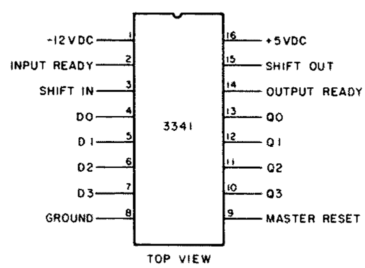

Fig. 3. 3341 connection diagram.

The main register contains sixty-two 4-bit characters, with one 4-bit character contained in each of the input and output registers, for a total of sixty-four character memory positions. Information may enter the input register on the D0 to D3 inputs when both Input Ready (IR) and Shift In (SI) logic is high. When data has entered the input register, IR goes low. Data remains in the input register a preset interval, at which time SI goes low. Data is then shifted into the main register. When the transfer is completed, IR will go high, indicating that the next entry may be accepted. If the main register is full, IR will stay low, blocking further entries. SI will now go high and the next character is accepted into the input register.

Information entering the main register is immediately shifted to the first open data position at the main register output. Transfer of a character from the main register to the output register occurs when both Output Ready (OR) and Shift Out (SO) logic is low. When the transfer has occurred, OR will go high, indicating that information is present at output pins Q0 to Q3. Transfer out of the FIFO takes place when SO logic goes high. OR logic now goes low, followed by a low on SO which again allows a character to enter the output register. SO logic can be controlled by a clock to provide an output speed control.

The 3341 FIFO may be expanded in sixty-four character steps by stacking individual chips. Fig. 2 indicates the serial stacking method. No external logic is required. If character data of more than 4 bits is required, the FIFO may also be expanded in parallel to increase capability in 4-bit steps. In this case, external logic is required to ensure that the input and output logic on each chip is ready before character transfer is attempted.

Refer to Fig. 3 for the 3341 connection diagram. Note that both a +5-V-dc and a −12-V-dc power source is required.

The typical home-brew keyboard probably employs either the diode matrix or the toroid transformer method of character generation. Both methods generate several parallel data pulses, the number depending on the specific CW character, which are fed into a shift register. The shift register converts the parallel data bits into serial data bits. These serial data bits form the CW character.

The FIFO is inserted between the character generator and the parallel-to-serial shift register. System speed is controlled by a clock input to the FIFO to control SO rates. A register content indicator is an option to inform the operator when the FIFO is approaching full memory status.

One keyboard design,[1] recently available as a PC board kit, is an excellent example of FIFO application to the toroid transformer method of character generation. Referring to Fig. 4, note that the character generator is 8 bits wide, requiring that two FIFO chips stacked in parallel be used. The required input logic begins with U1. A high pulse on any one of the eight character bits will cause a low U1 output. This low is inverted to a high at the input of U2A. When the IR in-

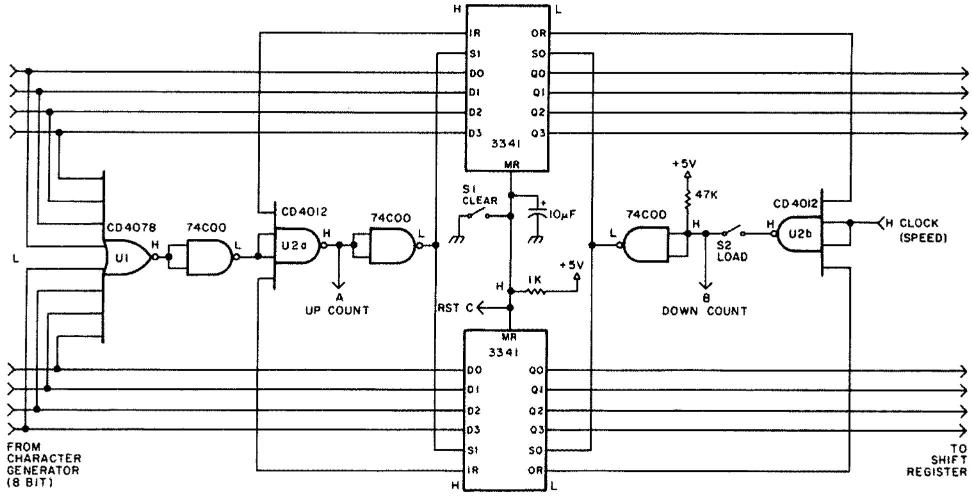

Fig. 4. FIFO parallel stacking to accommodate an 8-bit character. Logic indicated is with circuit at rest.

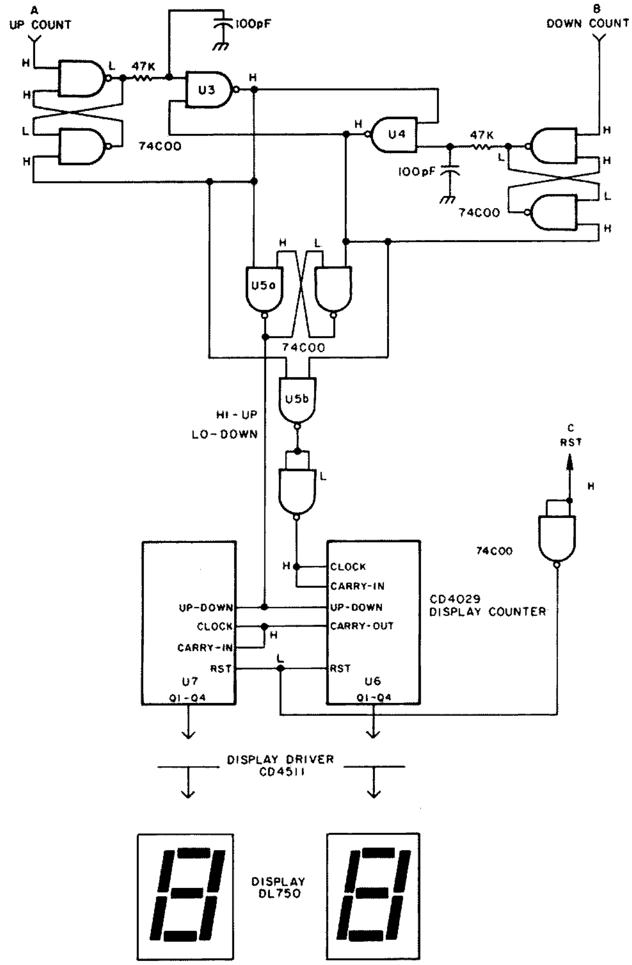

Fig. 5. FIFO register content count. Logic indicated is with circuit at rest.

puts to U2A from each FIFO are high, indicating the FIFO is ready to accept data, the output of U2A goes low. This low is inverted and appears as a high at the SI input at each FIFO, indicating that data may enter the input register. This logic ensures a coordinated flow of data into the FIFO stack.

Characters stacking up at the FIFO output are shifted out according to the speed control setting. When OR goes high on both FIFOs, indicating a character is present in the output register, a low will appear at the output of U2B. This low will occur at clock speed as long as information is flowing into the output register. If S2 is closed, the low is inverted and places a high on the SO pins of both FIFOs, and information may flow into the parallel-to-serial shift register. If S2 is open, the low cannot be inverted and the FIFO will fill to capacity. This feature allows the operator to pre-load a message into the FIFO for later transmission at the flip of a switch. The FIFO can be completely cleared by S1.

A memory content indicator, while not an absolute necessity, is certainly a worthwhile convenience. The previously mentioned design also provides an excellent example of one method of memory count logic. Referring again to Fig. 4, note that up-count, down-count, and reset inputs to the memory counter are obtained at points A, B, and C. Counter logic is displayed in Fig. 5.

U3 receives and inverts an up-count pulse from the input gating. The low output from U3 inhibits a down-count from U4 and drives the output of U5A high. A high appearing at the up/down terminal of the display counter will initiate an up-count, provided clock and carry in logic is low. The low from U3 also appears at the input to U5B, which causes the output to go high. This high is inverted and provides the necessary low at the clock and carry in terminals of the counter. This process is repeated for a down-count except that a low appears at the up/down counter input. When the count in U6 reaches its maximum count, carry out logic will go low. This low appears at the clock and carry in terminals of U7, which initiates a ten count at the next up-count command.

A buffer-equipped keyboard is truly a joy to operate. When sending at speeds below your typing ability, just fill the buffer, then sit back and compose your next sentence. The down-count will tell you when to resume typing. You can easily tell when you are approaching speeds that tax your typing ability. Just keep an eye on the memory count. If you cannot build up a lead, turn down the speed control and give the buffer room to function. Quite often your contact will sign his call after each transmission. This time can be used to fill the buffer and be set to go at first opportunity.

All logic for the example design is readily available through advertisers in this magazine. The buffer section requires one each of the 74C00, CD4012, and CD4078 logic in addition to the two FIFOs. Currently, this will cost about $15. The two each of the CD4511, CD4029, and DL750, and the three 74C00s in the counter section will cost about $10.

If you have a question on this article, an SASE will bring a prompt reply. ■

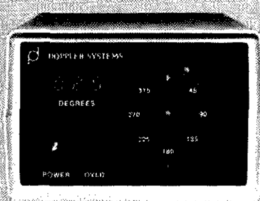
DIRECTION FINDING?

★ Doppler Direction Finding
★ No Receiver Mods
★ Mobile or Fixed
★ Kits or Assembled Units
★ 135-165 MHz Standard Range



★ Circular LED Display
★ Optional Digital Display
★ Optional Serial Interface
★ 12 VDC Operation
★ 90 Day Warranty

New Technology (patent pending) converts any VHF FM receiver into an advanced Doppler Direction Finder. Simply plug into receiver's antenna and external speaker jacks. Use any four omnidirectional antennas. Low noise, high sensitivity for weak signal detection. Kits from $270. Assembled units and antennas also available. Call or write for full details and prices.

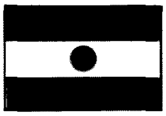
73 INTERNATIONAL

Each month, 73 brings you amateur radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73: Amateur Radio's Technical Journal, Pine Street, Peterborough NH 03458, USA, Attn: Avery L. Jenkins WB8JLG.



INDIA

The Bangalore Amateur Radio Club had its club night on Sunday, March 12, 1983. This annual function is specially held to bring ham families together. This year, the function coincided with the 70th birthday of OM Girimaji VU2GX. He was given an autographed memento by all the hams present. (See photos.)

GARDEN CITY CONTEST

This is an annual CW contest jointly organized by the Bangalore Amateur Radio Club (VU2ARC) and Visvesvaraya Industrial and Technical Museum (VU2VTM). This contest is essentially conducted to promote the DX capabilities of VU2 hams. It is held in the third week of December every year between 1200 GMT on Saturday and 1200 GMT on Sunday. The frequencies of operation used are 7 and 14 MHz.

Message Exchange: RST report with a three-digit serial number of contact (599039 = 39th contact).

Eligibility: Contest is open to all licensed amateurs worldwide.

Type of Operation: Single operator.

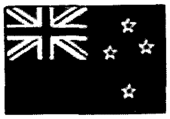
Classes of Entry: Group A for VU2s holding grade I license. Group B for VU2s holding grade II license. For non-VU2 hams, no group classifications.

Scoring: Points earned by VU2s for making complete contact with Asia, including India—1; Europe, Africa, and Australia—2; North and South America—3. DX stations score 1 point for every VU2 contacted.

All entries to the contest must be postmarked not later than 15th January and addressed to: The Convenor, Garden City Contest, Bangalore Amateur Radio Club, PO Box 5053, Bangalore-560 001, India.

There is no entry fee. True copy of a contest log must be submitted with sender's name, call, address, etc.

The three top scorers in each class will be awarded the winning certificates. All contestants submitting valid logs will also receive certificates of participation.



NEW ZEALAND

Des Chapman ZL2VR
459 Kennedy Road
Napier, New Zealand

June in New Zealand is the month when the shortest day occurs (signifying the middle of the the winter season) and also the month when the New Zealand Association of Radio Transmitters (NZART) holds its Annual Conference and Convention. It is the time when the members get together to attend the Annual General Meeting and discuss the policies concerning the running of our Association. Also held are the annual meetings of the various sections of the NZART: WARO, the Women's Amateur Radio Operators, OTC, the Old-Timers Club, AREC, the Amateur Radio Emergency Corps, and forums of the VHF groups, the Novice Radio Training Scheme, and the DX buffs.

The weekend program also includes plenty of social- and radio-oriented activities—trade displays, trading tables for hams and XYLs and YLs, a dinner dance, a fox hunt on 2 meters, a mobile rally on 80 and 2 meters, and, over the past couple of years, several technical seminars and forums as well as the usual rag-chewing that always forms part of any ham get-together.

The venues of the Annual Conferences are set about two years in advance so that the branch responsible for the organization of the Conference has plenty of time for the planning of it. The Conference is held in a different city or town every year; last year it was the turn of my hometown, Napier, because it was the 50th anniversary of the formation of the Amateur Radio Emergency Corps (AREC), our emergency communication network. The AREC was born about 12 months after the devastating earthquake which hit Napier and the surrounding areas in February, 1931, when several amateur radio operators, including three within the devastated areas, maintained emergency communications for several days after the first shocks of the earthquake. As a matter of interest, some of the emergency signals were received in the United States and were the subject of an article in *QST* in 1931 or 1932.

As a result of these emergency operations, the amateurs of New Zealand saw the necessity for some form of emergency group to be available at any time to provide emergency radio communications. Since its inception, the AREC has assisted in hundreds of emergency situations including earthquakes, floods, land subsidences, aircraft crashes, mountain and bush rescues, and shipping disasters. This year's Conference was held over the first weekend in June (which is a long holiday weekend in New Zealand) at Dunedin, the main city in ZL4-land.

Next year's Conference is scheduled for Palmerston North, a university city in the center of the lower half of New Zealand's North Island. The city has some wonderful conference facilities, both in the city itself and at the university, and boasts of pleasant public gardens and recreational facilities. Overseas visitors are always welcome at our Conferences, and we have had visitors from VK, VE, W, and some of the Pacific islands in past years. So, if you are contemplating a ZL holiday, what better time to come to our fair land than at Conference time in June? If you are interested, a letter to NZART or myself will supply you with the necessary information. Even though it's winter time, a very warm welcome awaits you; the winters are reasonably mild in ZL since only the high country areas and the mountains are snow areas.

NZART NATIONAL FIELD DAY

NZART holds an annual Field Day contest each year during February, when

Photo A. (left to right) Back row: VU2IR, 3 SWLs, VU2KVR, VU2AUS, 2 SWLs, VU2RVS, VU2RRN, VU2RO, SWL, VU2GX, SWL, VU2GSM, and VU2YZ. Center row: families and VU2UV. Front row: VU2NRS, VU2USA, VU2KAX, SWL, VU2RXZ, VU2RAH, VU2VNS, and VU2VIZ.

NZART branches go portable in the field. The contest is over two days, Saturday and Sunday, the operating periods being from 1500NZST to 2400NZST, Saturday, and 0600NZST to 1500NZST, Sunday, and the frequencies used are 80 and 40 meters, CW and phone.

Field-Day stations must operate from a portable power supply, in a tent or trailer (caravan), or some other portable location, e.g., a car or mobile home, on antennas erected for the Field Day no earlier than 1200NZST on Saturday.

Our Field-Day contest this year was one of the most successful for some time. In all, over 56 branch stations operated during the two days, out of a possible 80 branches. Contacts are on phone and CW in each hourly period, with points allotted for contacts and multiplier points for the number of branches worked on each band and mode. Some overseas contacts are admissible, with stations in VK and some of the near Pacific islands only.

My local branch station was set up on the banks of the Tutekuri River, about 3 miles from the center of town. The station was set up in a tent and a mobile camper. We used tall poplars about 120 feet high for antenna supports, placing pilot lines over the top of the trees with a surf-casting rod and line. We had 80- and 40-meter dipoles at about 80 feet, a delta loop on 40 meters, and a long-wire about 500 meters long across the river as our other 80-meter antenna.

The team had 1500 contacts, for 181 multipliers, giving us a total of just over 1,000,000 points; we did not think that we were the winners, as there were two or three teams ahead of us! The station was operated from the club's portable motor generator, supplying 230 volts to the four rigs used: a Kenwood TS-930S, a Yaesu FT-101, a Yaesu FT-901, and a FTDX-401—a rig on each of the modes on the two bands used.

I hope to be able to include some of the photographs taken at Field-Day locations in a future column to illustrate the similarity between our Field-Day exercises and yours (wherever you live), as hams around the world have a lot in common concerning our hobby.

BITS 'N' PIECES

June was the diamond jubilee for one of New Zealand's original ham operators, Dan Wilkinson ZL2AB, who was allotted his callsign in June of 1923. His was the third to be granted, and he still holds the same original call today. Who knows, that could be some sort of a record. Incidentally, the first call was issued to Jack Orbell 3AA, and #2 was 4AB, the Otago Radio Society. Another early call issued in 1923 was 1AC to Len Spackman, and he, too, still holds that same callsign and is active on the Old-Timers Club Net, so his diamond jubilee will be due later this year. Dan ZL2AB is also heard regularly on the Old-Timers Net on Sunday mornings on 40 meters.

AREC PHILATELIC COVERS

A small quantity of special commemorative philatelic covers is available. Issued to commemorate the 50th anniversary of the foundation of the Amateur Radio Emergency Corps, the covers were postmarked with a special cachet in June of last year, at the time of the Annual Conference and Convention. They are unaddressed and will be sent under a separate outer cover to avoid damage.

Please send 6 IRCs for one cover by return 2nd class airmail. Send applications to Napier Branch 25, NZART, PO Box 4030, Napier, New Zealand.

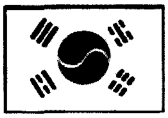
DX NEWS

Chatham Islands. . . Allan ZL2BKM has been operating from the Chatham Islands since April and will continue until August 29, 1983, all bands, CW and phone. Allan is a radio operator in the New Zealand Post Office, and he is doing a tour of duty at the Chatham Island Coast Radio Station run by the NZ Post Office. Allan's rig is a TR-430S. When he leaves the Chathams, he will be traveling to the States with a group of New Zealand hams to attend the Seattle NEZCHEQ get-together over the US Labor Day weekend, September 2-3.

Niue Island. . . Peter ZL2IK has taken the position of Director of Telecommunications, Niue, a two-year tour of duty which started in mid-May. Peter is a 160 buff and will be endeavoring to work DXCC on 60 and, if it is possible, 160 during his stay in Nuie. He also will operate on the other HF bands. His rig is an IC-720; he will be ZK2IK.

Also operating from Nuie at present are two other ZL operators, Bob ZK2RS and John ZK2JS, both telecommunications technicians on tours of duty in the islands. Both of these operators are also active on the HF bands, and when these two are joined by Peter, they probably will make quite an impact on the DX front. So the DX boys will be sure of Nuie being active for some time in the future—at least until 1985 when the present ZLs' tours of duty will finish. But then let's hope more hams from ZL will take their places when they return to New Zealand.

Penrhyn Island. . . Warwick ZL3AFH has been active operating from Penrhyn, in the Northern Cook Islands, as ZK1WL. He will operate until some time around the middle of this year.



KOREA

J. Michael Wengert HL9KT/KH2AC
CPO Box 2961
Seoul, Korea

In the spring, a young ham's fancy turns to operating portable! Koreans are natural outdoorsmen and love to climb rocks and mountains, camp at the seashore, and generally commune with nature. A dream situation for a young Korean ham might be camping in the mountains with his favorite rig and perhaps YL. Realizing that dream, however, has been a difficult thing for Korean hams.

In the past, portable/mobile operation required permission from the MOC (Korean Ministry of Communications) in the form of a special callsign, but such operation was possible. An important restriction was that operation was not permitted in certain areas near the demilitarized zone (DMZ) that separates the hostile states of the Republic of Korea and North Korea, for obvious security reasons. Well, no matter where you go, there is a "wrong-way Charlie," and Korea is no exception. Violation of this taboo by a single ham resulted in cancellation of the privilege for all.

Efforts to regain the portable/mobile privilege are expected to come to fruition sometime this year. VHF handie-talkies are popular here but have been prohibited for use outside the shack. Most 2-meter FM operation is with Japanese mobile-type transceivers, so the changeover to mobile operation would be easy. Along with the question of permitting portable/mobile operation in Korea, the MOC is also considering issuing licenses for repeaters. In Korea's mountainous terrain, repeaters are a necessity for serious mobile work.

When portable/mobile operation is finally a reality, it will have been in no small part because of the efforts of Mr. Lee Hae Soo HL1BO, one of the pioneer hams in Korea and several-times director of the KARL. He has devoted much of his time and energies to regaining those privileges. He was instrumental in setting up the Korean National Red Cross regional club station system for use in time of national disaster and introducing the concept of amateur radio as a public service rather than a self-serving hobby. Much of this work has served to convince the Korean authorities of the value of amateur radio to society and encouraged them to liberalize the rules and regulations applying to amateur operation. A *73* International salute to HL1BO!

Much confusion regarding QSL Bureaus took place when the Korean hams changed over from HM to HL prefixes as a result of the 1973 WARC. Until that time, only US Forces/United Nations Command personnel used the HL prefix. To further complicate things, at about the same time, the USFK/UNC QSL address changed.

Following is the *correct* information: HL9 stations—American Amateur Radio Club of Korea, c/o Dependent Mail Section, APO San Francisco CA 96301; all other HL stations (1,2,3,4,5,8,0)—Korean Amateur Radio League, CPO Box 162, Seoul, Korea.

One final note. . . when signing with a Korean station, if you really want that QSL card, *never say Sayonara!* Koreans are completely different people from the Japanese. The correct farewell would be *Ahn-young!*

Well then, Ahn-young and 73 from the Land of the Morning Calm.

CANADA

(Reprinted from the CARF News Service Radio News No. 7/83 *by permission of the Canadian Amateur Radio Federation, Inc.)*

As the old saying goes, you win some, you lose some, and here's some proof. The same Privy Council Office which held up proposed license increases so long that they could not be implemented this year has been sitting on proposed revisions to the amateur regs since last May. The proposed changes which surfaced a couple of weeks ago were some of those which resulted from recommendations made to DOC (Department of Communications) by amateurs at the 1981 CARF Symposium. Included were revisions which would lift power restrictions on 160 meters, permit repeaters on 10 meters, allow European amateurs to use all of the two-meter band while operating in Canada under a reciprocal operating agreement, and redefine permitted bandwidths for AM, FM, FSK, and ATV. DOC hopes that now that these drafts which it had submitted to the Privy Council have been found, they will be approved fairly soon.

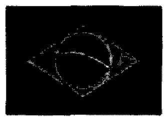
British Columbia amateurs were involved in a novel way in the recent Royal Tour activities in Vancouver. During the ceremonies connected with the upcoming 1984 World Exposition, held in the new BC Place, the Queen's speech on March 9 was relayed by a 450-MHz link to Vancouver repeater VE7RPT and retransmitted on 20 and 40 meters. To mark the event, BC amateurs were allowed to use the prefix XO. A special QSL card is available to listeners who report hearing the broadcast. VE7 stations who used the XO prefix can obtain a special QSL card free from the BC government.

TOWERS COLLAPSE

The worst ice storm in Manitoba's history hit in early March and put Brandon and Baldy Mountain repeaters out of business when the broadcast towers holding their antennas collapsed. Many amateurs lost their antennas and some had the tough luck to lose their towers as well, according to VE4MG.

CORDLESS TELEPHONES

The cordless telephone, like CB radio, is rapidly becoming a fad, and like CB radio, it already poses problems for amateurs. QRM from these devices is already showing up from their harmonics in the 40- and 80-meter bands and some of them are, according to a US source, being crystalled in the 160-meter band. DOC is currently working on some regulations concerning them. Just to complicate the scene, there is apparently a 25-Watt amplifier now on the market. The phones themselves operate duplex, using 49 meters and 1.6 to 1.8 MHz, although the latter slot is going to the broadcast-band expansion in a couple of years. These things work well, but the Consumers' Association of Canada points out that with some models which have dial-out facilities, it is possible to access another telephone line and rack up toll-line charges on it.



BRAZIL

Carlos Vianna Carneiro PY1CC
Rua Afonso Pena 49, Apt. 701
20270 Rio de Janeiro, RJ
Brazil

YL FROM BRAZIL

Need a "sure QSL" from Brazil? Looking for a YL contact for your YL award? Well, all you have to do is come to 14.248 kHz every Wednesday from 1900 to 2100 UTC and join the BRYLA (Brazilian YL) net. The net has existed since March, 1976, and is directed by Inge PY2JY. The net attracts YLs from all of the Brazilian states on both SSB and CW.

Inge has held her license only since 1970, but she fell so in love with amateur radio that she now has 290 countries and holds this BRYLA net to stimulate DX operations with Brazilian YLs and to spread the BRYLA Award to all places and continents. 159 of these awards have been sent to 35 countries of the 105 countries filed by the net.

Listen to PY1YL, PY1AIP, PY1LMS, PY1MF, PY1DVQ, PT2ML, PT2SV, PT2LS, PT2TF, PT2DCR, PY2ATL, PY2DLZ, PY2FL, PY2JY, PY4AKL, PY4ML, PY4DY, PY4RA, PY2ACR, PY5BZN, PY7AVN, PY7VBG, PY8SSB/7, PS8YL, and many others on the BRYLA net, and most of the requirements for the BRYLA Award will be fulfilled.

The BRYLA Award was created by Therezinha PT2TF, and it is great! DX stations must prove a two-way QSO with 12 YLs from different countries on three continents, plus 8 YL stations from Brazil—on any band, any mode, and all QSOs from 1975 on are valid.

The log must be certified by a radio association and must include the station, date, time, mode, report, and band. SWLs also may qualify. Send QSLs for files and

10 IRCs to BRYLA, c/o Ziza PT2LS, PO Box 07/0004, 70000 Brasilia, DF, Brazil, South America.

On the BRYLA net, you can find Eva PY2PE, DXCC Honor Roll member, Tessy PS8YL and Marilia PY4AKL, who both have more than 300 countries, Inge PY2JY with 290 countries, and PY2ADI with 172 countries. Ziza is BRYLA Award Manager with hundreds of first-class awards including 5 BRYLA Awards which were endorsed all CW.

When propagation is fine, Japan, Hawaii, New Zealand, Australia, and many other first-class DX stations are available.

A general CQ is called aiming the beam to South Africa, Asia, or Europe, and traffic is passed just like other international nets. Each YL is listed and one by one they QSO the other participants. No "chats" are allowed during these two hours so all calls can be answered. Only a call and report will be given by each YL.

Another very funny award was created by Inge, the WBYL (Worked Brazilian YL) Award, and it has been offered since the first day of 1981, with the first request coming from South Africa. Just contact 8 Brazilian YL stations and form the words "BRASIL YL" using any one letter from each suffix. One of the YL stations must be a PY2. Any band, any mode. The standard log is required, including station worked, date, time, mode, report, and band. SWL entries are also accepted. Send QSLs with 10 IRCs for return postage to Inge Tobias de Aguiar PY2JY, Rua Texas 448, 04557 Brooklin Novo, Sao Paulo, Brazil, South America.

Inge is so enthusiastic for radio, she was the first YL to operate VHF from a hot-air balloon flying over Sao Paulo, on August 18, 1974. She was with her husband Jose PY2JO and Vitorio Truffi, balloonist and proprietor.

She also participated in two DXpeditions to Arvoredo Island in 1975 and 1980. This island is the most beautiful small island in the world and is located at 46° 10' W and 23° 58' S, 176 miles from Rio de Janeiro. It was developed and maintained by Fernando Edward Lee.

There are hundreds of birds and fishes which come from distant places to the island. The island also has the largest wind alternator in the world, a lighthouse, solar water heating, a rainwater reservoir with a 1-million-liter capacity, and coconut trees which give 12,000 liters of coconut milk each year. There is also a 70-ton crane which can easily lift a 3-ton yacht into a specially-designed tank. Paradise on Earth, says Inge.

A new net is being planned and studied for 14288 kHz on Wednesdays at 2330 UTC. It will be beaming toward the USA and Canada.

LIBERIA

Brother Donard, Steffes, C.S.C.
EL2AL/WB8HFY
Brothers of Holy Cross
St. Patrick High School
PO Box 1005
Monrovia, Republic of Liberia

Liberia is on the westernmost point of the great continent of Africa. Most of the country is nearly at sea level, although there are parts of the interior that rise to somewhat over a thousand feet. For whatever reason, the amateurs in this country enjoy excellent communications conditions with the United States, all of Europe, and in the direction of Russia during the greater part of the year. It seems to be well situated geographically and it is in the GMT time zone.

The amateurs in the country number less than a hundred and most are not natives. The reason for this situation is simply that Africans have had little opportunity to learn amateur radio and, for the most part, they do not have the money to purchase and operate radio equipment. Very few of the cities have electrical power and those that do have it for only a part of the day.

The Liberian Amateur Radio Association (LARA), under the direction of Mr. Benjamin Walcott, is doing everything in its power to reverse those statistics. Radio classes are being run in increasing numbers and the response is very gratifying. In Monrovia, a course is being taught currently at St. Patrick High School, and the turnout is over a hundred persons of all ages and includes both men and women. These classes operate under great difficulty since textbooks are not available and things like code oscillators are rare. The students must rely on class notes and on duplicated pages which are prepared and handed out by the instructor. Many of the people have tape recorders, which are a great help.

When the students are licensed, there is the problem of equipment for them to use. The association plans to gradually set up club stations in strategic areas so that those who do not have their own equipment may have access to a club station. At the present time, there is one such club station in operation. The equipment for these club stations will have to come from amateur friends in other parts of the world. The station which is presently operational was donated by a radio club in Barberton, Ohio.

The Telecommunications Ministry here in Monrovia has neither the personnel nor the funds to test and evaluate applicants for amateur licenses. The government relies on the LARA to do this job for them. The LARA instructs persons interested in amateur radio, tests them, and when they have met the requirements, recommends them to the Ministry for licensing. This system is working remarkably well and the cost to the government is minimal.

Amateur radio in Liberia is proud of its record of performance in times of emergency and disaster. It measures up to the high standards of amateur radio around the world, and it is the aim of the LARA to expand the numbers of operators, increase amateur activity, and at the same time maintain the high standards at which it now functions.

(Brother Donard is Secretary of the Liberian Amateur Radio Association.—Ed.)

GREAT BRITAIN

Jeff Maynard G4EJA
10 Churchfields
Widnes WA8 9RP
Cheshire, England

The continuing growth of interest in amateur radio in the United Kingdom was evidenced recently when the Radio Society of Great Britain (RSGB) held a National Amateur Radio Convention at the National Exhibition Center near Birmingham. The NEC is a prestige exhibition and conference center with its own airport, railway station, and hotel complex situated more or less in the center of England and well served by motorways (freeways).

I had previously visited NEC for trade shows such as Communications 83 and the International Business Show and had found parking easy and queues minimal. Not so with the RSGB, who, although using a hall of adequate size, had arranged for only two ticket counters to be open. This meant a wait of some twenty minutes in a fresh breeze which at least sharpened our minds for the coming fray.

The majority of major importers were exhibiting the latest in Japanese microprocessor-controlled black boxes. I tried, unsuccessfully, to find a new rig that performed better than my FT-101 rather than just outdid it in numbers of knobs. There are no longer any indigenous manufacturers of HF gear in the UK. However, we do have some able representatives in the specialist scene including Microwave Modules and Wood & Douglas. MM displayed its range of transverters for 2 meters and 70 centimeters, together with linear amplifiers for these and higher bands. Perhaps their most innovative product (and one that always attracts attention) is the Morse Talker. This microprocessor-controlled device sends random Morse at a user-selected rate and then speaks the letters sent for the pupil to check his copying. As an option, the model two will interpret (but not comment upon!) pupil-sent Morse.

Wood & Douglas exhibited a range of 70 cm, 2-, 4-, and 8-meter kits, and modules for the construction-minded operator. As well as traders, the exhibition hall included the various support groups such as the RSGB (showing its extensive range of books), AMSAT-UK, selling the newly-published *Technical Handbook*, Navy and Air Force Amateur Radio Societies, the Radio Amateur Invalid and Bedfast Club, and BARTG (the British Amateur Radio Teleprinter Group).

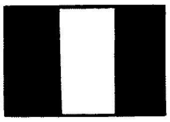
With most of the stands 5 deep in excited people clutching for leaflets, it was something of a relief to take a break for lunch. This is an area in which we have a little to learn from the US. The choice at NEC was to queue for half an hour for a very soggy beefburger or (as we did) walk over to the attached Metropole Hotel and pay over the odds for an average meal.

Many believe that the intense interest in amateur radio is a spin-off from the recently legalized CB service (27 MHz, FM, 4 Watts) which many are finding frustrating and uninteresting (surprise, surprise!). Lots of ex-CBers are furiously studying for the radio amateurs' examination, which twice yearly opens the doors to those answering the questions correctly.

Some early problems with CBers spreading into the 10m band have now largely disappeared. My own local cowboy was discouraged from using 28.1 for SSB by some 200-Watt RTTY tests I ran! There is, however, some worry over here about the 10m band and its lack of use during quiet sunspot periods. Moves are afoot to encourage FM around 29.6 for mobile-to-mobile working (many 2m repeaters are very busy indeed).

Cheap CB rigs ($25.00 to $50.00) are being snapped up and converted from 27 to 29 MHz quite easily. Although low in price, some of these are from well-known names such as Icom and offer a range of facilities including 40 channels.

The RSGB is encouraging 10m usage by promoting a new 28-MHz Counties Award. This requires confirmed contacts on 10m (any mode) with 40 UK counties/Scottish regions from the total of 77. Contacts must be made after April 1, 1983. The award is free to RSGB members and $3.00 to others.



FRANCE

Claude Guee F1DGY
11 Rue Emile Labiche
28100 Dreux, France

2M FM REPEATERS

About 25 FM repeaters are located in France. Placed on 15 channels in 25-kHz steps, they can be found between 144.725 and 145.175 MHz, with a +600-kHz offset. ERP is between 20 W and 200 W. Some are very busy.

70-CM FM REPEATERS

France has about 10 of these repeaters. Present channels of the machines will be moved, but all have a −1600-MHz offset.

AWARD: DIPLOME VILLE DE PARIS

HF bands: Class 1—contact 20 arrondissements, Class 2—contact 15 arrondissements, Class 3—contact 10 arrondissements. All contacts after January 1, 1946. A log book certified by an officer of the national organization is required. Fee: 30 FF (IRC).

For YL: 10 arrondissements, or 20 for "diplome d'honneur."

Diplome manager: Bernard Louis F5BL, 15 Place d'Aligre, 75012 Paris, France.

WORLD COMMUNICATIONS YEAR

For this event, French stations are authorized to use a TO prefix.

SATELLITE ACTIVITY

RACE (Radio Amateur Club de l'Espace) is supporting ARSENE (Ariane Radio Amateur Satellite Enseignement Espace). This satellite is scheduled to be launched by Ariane IV by the end of 1985. Two modes are planned: B and F (2.4 GHz and 435 MHz). The orbit will be an equatorial ellipse. The president of RACE is F8ZS and the vice president is F8YY.

SWITZERLAND

Peter W. Frey HB9MQM
PO Box 1127
CH-5401 Baden
Switzerland

As in most other Western countries, repeaters are an important aspect of amateur radio in Switzerland. However, in the last couple of years, many amateurs in this country have grown increasingly skeptical about what some call "garbage-in-garbage-out machines." They charge, for example—not entirely unfounded—that repeaters tend to promote bad operating practices and that the difference between what you hear on 27 MHz and on 145 MHz has become rather marginal. Monitoring a 2-meter repeater like HB9AN near Zurich, the biggest Swiss city, for a day can indeed be a frustrating experience: QSOs abound with CB-type lingo and their content is only too often in violation of the rules. (Remember, for example, that third-party traffic of any kind is an absolute no-no in almost all of Europe!)

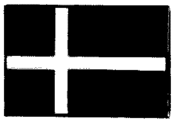
So far, repeater jammers in Switzerland haven't had to fear much in terms of getting caught. Some repeaters, like HB9F on top of Mount Schilthorn (known to James Bond 007 movie addicts as "Piz Gloria") in

the Bernese Oberland or HB9RW on top of the Parpaner Rothorn in the southeastern part of the country, are situated well above 9000 feet. They cover a great part of Switzerland and considerable portions of neighboring countries, thus making it a rather difficult task to locate and track down a jammer. On top of that, the radio surveillance people of the Swiss PTT can't provide as much help as the amateurs sometimes expect. They are facing enough problems already in coping with the messy 27-MHz situation in this country.

For the officials of the Swiss national society, repeaters are a constant item on the agenda. It's the business of repeater coordinating that sometimes gives them headaches. If you thought repeater coordinating was difficult in the US, imagine just how it is to coordinate repeater frequencies when societies and authorities of some five countries are involved!

The 2-meter band plan of the International Amateur Radio Union Region 1 (Europe, the Soviet Union, and Africa) provides only for ten repeater channels designated RØ to R9 with inputs located between 145.000 MHz and 145.225 MHz and outputs 600 kHz higher. You don't need to be a repeater-coverage expert to see that it is close to impossible to cater to all wishes with only ten channels available. Therefore, repeater problems are an everyday fare for the VHF managers of Europe's national societies.

A few years ago, one could even witness a "repeater war" in Central Europe. The French national society unilaterally decided to put into operation a couple of repeaters on frequency pairs well apart from the internationally-agreed-on channels and with inputs right in the middle of the 2-meter-beacon band. The Austrians closely followed suit. Through a lot of negotiating across country borders and shuffling around of channels, the problem is now in the process of being resolved. However, when you're experimenting with HB9W, the flea-power (36 mW!) S-meter calibrating beacon on Zurich's Mount Uto, you still stand a good chance that your test is rendered useless because of constant interference. The input of an Austrian repeater on Mount Valluga just across the border is on exactly the same frequency.



DENMARK

Hanne Nielsen OZ1CID
Hvidovrevej 468
2650 Hvidovre
Denmark

In Denmark we are 8000 radio amateurs strong, and about 7000 are members of EDR (Experimenterende Danske Radioamatører). Under EDR we have 60 local divisions of varying size.

The Copenhagen Division, or as we call it, club, is the biggest, with 300 members. We have our own house bought in 1974. The club was founded in 1932 and we have just celebrated our 50th jubilee.

During the week, we have many activities. Monday evenings we have a common meeting with lectures upon different technical sides of our hobby and afterwards comfortable talks over a cup of coffee and some eatables. Of course, the club station is on the air with the call OZ5EDR.

The EDR Copenhagen Division QTH.

Tuesday we have laboratory evening, where members can receive technical assistance for their problems with stations or construction projects or, as a group, we start some new projects. Four to five days every week, except in the summer time, we have technical courses and CW courses for those who want to have a license or upgrade their present license.

In the clubhouse, we have a laboratory, library, VHF/UHF shack, HF shack, instruction room, office, dining room, three apartments for leasing to members, a workshop, material rooms, and a newly established museum for radio amateurs. Outside the house, we have an antenna mast with HF/VHF/UHF beams.

Many weekends we join into the different national and international contests on both CW and SSB. Joining in Field Days and the Jamboree on the Air are also some of our activities. We also do a lot in award hunting. That special side of our hobby hasn't been going on for more than 4 years, but through many QSOs and a fine award manager, we now have got 104 different awards decorating our walls, many from *73* magazine. We have also founded 2 awards: The Copenhagen Award founded many years ago, and the OZ Prefix Award founded on the occasion of the 1982 jubilee.

The house we own is very old. Every weekend some members work on it as there is always something to do and we are not able to pay workers from outside.

It's very nice, as a chairman, to see that our hobby, amateur radio, is flowering, not only in the Copenhagen Division of EDR, but everywhere. If any radio amateur in the USA should visit Copenhagen, you would be very welcome to visit our club.

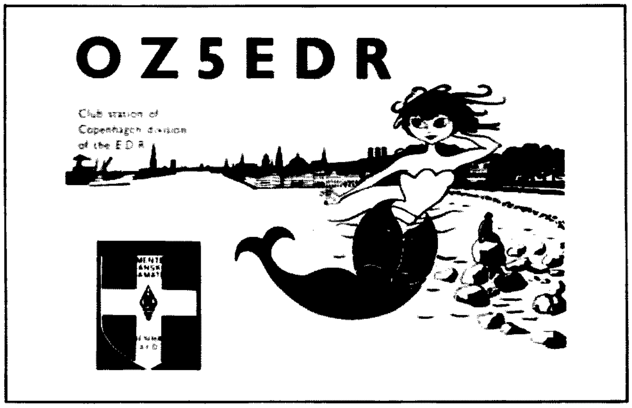
SCANDINAVIAN HORIZON

"Do you always carry your radio with you whenever you travel?" the customs lady asked me at Logan Airport in Boston, Massachusetts, when I unloaded the two 40-pound boxes with ham gear in addition to our 5-person family luggage. "Yes, I always do," I replied, and she let us pass through.

Most of us hams like to have our radios with us when we travel. It sure is fun to experience how the bands sound at a distant location from home. A 2-meter FM handheld can give you lots of opportunities to meet local hams during a vacation in a foreign country. Many of you Americans have been fortunate enough to be able to use ham radio far away from home while in the service overseas. However, only some twenty years ago or less, a citizenship in the licensing country was required. Luckily, this has changed in recent years. Many countries now have formal reciprocal agreements for temporary licenses for foreign visitors.

A DREAM COMES TRUE

You are planning your trip to some foreign country and you would like to operate ham radio while staying there. Start your



planning well in advance. If you have no information on licensing in the country concerned, write to their telecommunications authority or the amateur radio organization in that country for information. Addresses can be found in ham magazines and in the *Callbook*. The easiest way, though, is to write to your own national amateur radio organization for reciprocal licensing information.

Generally speaking, the following things are common in most European countries:

- A reciprocal licensing agreement between the two countries
- Application required
- Processing time, one to three months
- License issued for a period of maximum three months each calendar year
- Operating privileges in accordance with the class of license in the country you visit which is closest to your own license
- You have to follow the regulations in the country you visit which can differ a lot from what you are used to back home, especially maximum power limits and frequencies used

There are some important differences from country to country. The following is currently valid for each of the Scandinavian (Nordic) countries.

Denmark. An application with the following data should be sent to Radiotekniske Tjenste, Tilladelsessektionen, Islands Brygge 83 C, DK-2300 Kobenhavn S, Denmark: Name and address of applicant, date of birth and town, citizenship, callsign and class of license, time period for the stay in Denmark, address in Denmark, any remarks, and date and signature.

A photocopy of your license, certified by two persons, should be attached to your application. This procedure is accepted for applicants from the USA, Canada, Brazil, Australia, Portugal, Switzerland, France, Spain, Luxembourg, Belgium, West Germany, Great Britain, Holland, Iceland, Sweden, Norway, and Finland. Amateurs from other countries have to supply documents stating the requirements for a ham license in their country in addition to the license document.

The fee, 20 Danish kroner (around \$2.50), shall be paid when arriving in Denmark. A special money order form sent with the license should be used. The same procedure applies for the Faroe Islands, prefix OY.

Finland. The Finnish amateur radio organization, SRAL, has a somewhat different status than what is common in other countries. It is mandatory to be a member of the SRAL when being a ham in Finland. Your application sent to the SRAL will be handled faster than if sent directly to the licensing authority. The address is Suomen Radioamatooriliitto r.y., Postilokero 306, SF-00101 Helsinki 10, Finland.

The application shall state your complete name and address, citizenship, fixed station address in Finland, time period for the stay in Finland, any remarks, and date and signature.

A photocopy of your license and personal identification (photocopy of passport or similar document) is required. Finland requires reciprocal agreements. Non-Finnish citizens are prohibited from working mobile ham radio.

The fee is 38 Finnish Markka (around \$8.50) and the license is sent COD.

Norway. Norway also requires a reciprocal agreement, and application shall be mailed to Norwegian Telecommunications Administration, Radio Inspection Office, PO Box 6701 St. Olavs Plass, N-Oslo 1, Norway.

Preferably, you should send for their ap-

plication form which includes about the same data to be filled out as for the other countries. If you intend to operate mobile, the registration number of your vehicle shall be stated. If you intend to rent a car, you can state that. One important difference is that you have to enclose a Certificate of Good Conduct issued by your local police authority.

If you are a foreign citizen but a resident in Norway, you can apply for a license one year at a time. The prefix then is LAØ. Operations from the Norwegian territories JWØ, JXØ, and 3YØ are under separate regulations.

The fee is 50 Norwegian kroner (around $8.00), and shall be included with the application.

Sweden. Together with Denmark, Sweden is one of a few countries that does not require reciprocal agreements. We have agreements, however, due to the reason that otherwise we would not be able to operate in countries where they require such formal agreements. The application form includes the regular data and shall be sent to The Swedish Telecommunications Radio Department, Licensing Section, S-123 86 Farsta, Sweden. The application can be written in Swedish, Danish, Norwegian, English, French, or German. A copy of your valid license and a Certificate of Good Conduct (impunity) issued by the police authorities in your native country must be included. In certain countries, such a certificate cannot be obtained. A certificate issued by the applicant's amateur radio organization must then be included.

The fee is 80 Swedish kroner (around $13.50), and shall be sent after you have received your temporary permit. They prefer not to receive payments in advance.

Any foreign national with permanent residence in Sweden for a considerable time (currently 3 years) can get a permanent Swedish license. If holding a foreign license, the equivalent Swedish license will be issued without any further exams. However, one obstacle to getting the highest class of license, class A, is the code proficiency requirements. Most countries have 12 wpm as their highest code speed. A code exam at 16 wpm will solve that problem.

In both Finland and Sweden, you use your call followed by /OH or /SM and a number stating the district where the radio transmitter is used temporarily.

LG5LG and SJ9WL. These two callsigns belong to the same station located on the border of Norway and Sweden, not very far from Oslo, the capital city of Norway. The place is called Morokulien, a name combined of the word "fun" in those two languages. It is not a separate DXCC country, but you can operate this amateur station without any reciprocal agreements. The only requirement is that you show your valid ham license when visiting the station. You can rent the house with the station if you would like to spend a few vacation days there. However, if you want to rent, you are advised to make reservations.

COMPARISON WITH THE US

As a comparison, the reciprocal licensing for visiting hams in the US is very favorable. There is no fee, the license is issued for up to one year at a time and is renewable, and the processing time is short (usually sent by return mail), although the application form states 60 days. However, if your country does not have a reciprocal license agreement with the US and you want to operate from there, you can take the exams at an FCC (Federal Communications Commission) office. US citizenship is not required, and you can go through all exams at the same time if agreed upon by the local FCC office. You start with (e.g.) the 20-wpm code and then take the combined Technician/General class 70-question exam. If you pass, you can continue with the Advanced written exam and finish with the Extra. Then you just wait for the mail.

CONCLUSION

If you plan to visit a foreign country, apply for a license and you get a chance to meet the people. That is much more rewarding than all the tourist attractions in the world.

GREECE

Anastasios D. Panos SV1IG
4 Voltairou St., N. Kosmos
Athens 411
Greece

The Ministry of Communications, which is responsible for issuing licenses for new amateurs, announced that 43 hobbyists passed the tests in March. Exams are held twice a year in Athens, during March and September. Negotiations between radio amateur officials of the Radio Amateur Association of Greece (RAAG) and the Ministry of Communications are being made so that at least once a year exams are held in northern Greece (Thessaloniki). Newcomers to the hobby are issued a C class ticket which allows them to operate with 50 Watts on the HF and 5 Watts on the VHF bands, and this is the only limitation. They are free to operate any frequency in all bands and in any mode.

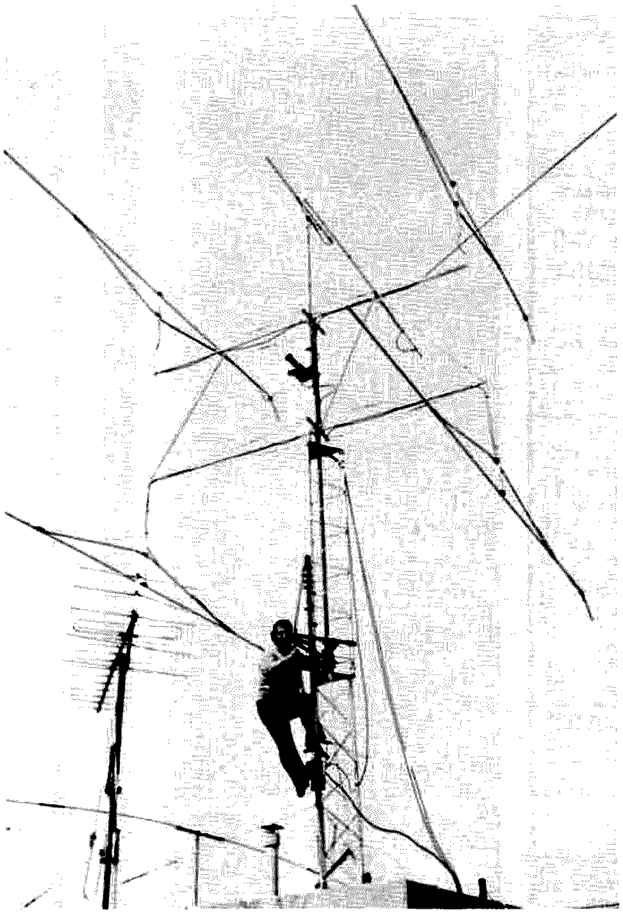
Elections for RAAG's new board of directors were held in February with about 1000 members, but only the 360 licensed members have the right to vote. The new board of directors is as follows: Evangelos Moustakas SV1AN, president; Kostas Fimerelis SV1DH, vice president, Kostas Thanopoulos SV1DC, secretary; Manolis Darkadakis SV1IW, treasurer; Dimitrios Konstantinou SV1GL, member; and Dimitrios Alexandris SV1LL, member.

Elections are held once every two years and candidates for the board of directors must be licensed members for at least 5 years. Members with the right to vote must be licensed and have at least one year in the association.

After a long waiting time, the new repeater R3 (145.075 in, 145.675 out) was placed at Heraklion, Crete Island. There are some problems with the antenna system, but these will be solved soon. Similar problems, plus interference in the input of the R2 repeater in Athens forced it out of operation, and it is in the fine hands of Dimitrios SV1GL. Besides the necessary adjustments and the placement of a duplexer, he is thinking of changing the frequencies from R2 to R7.

Kostas SV1OE, is quite an active radio amateur, one of the few hams who are working RS satellites, and the only one in Greece who makes moonbounce QSOs. His location is close to Hymetus Mountain, about 6 kilometers from the center of Athens. His shack is composed of Kenwood and Yaesu VHF rigs and he uses a Kenwood transceiver for HF. His antennas are a set of four (F9FT) yagis and several dipoles for HF. He is active on the 1296-MHz nets, using the yagi and a parabolic antenna of his own construction. Kostas transmits the A5 mode and his 3-D pictures were really impressive. He is anxious to work the Phase III satellite.

A visit to the Voice of America installation was made by the radio amateurs of Greece. At this visit, a demonstration of high-power transmitters and antennas was given at the transmitter site of Xanthi, Greece. Most of northern Greece's radio amateurs attended, and Bad SVØBK, deputy director of the station, was present at the dinner. He showed them the big complex of antennas used and the transmitters and the voltage generators that keep VOA independent from power lines.



Konstantinos Gioulseren SV1OE.

Attention: Here is required reading for any radio amateurs coming into Greece and bringing their gear. It is against the law to bring a radio into the country if a permit has not been issued by the Ministry of Communications. If caught, you may be charged with illegal possession and/or use of radio, with up to two years imprisonment and/or up to a $2,500 fine as punishment.

Via Stradella, 13
20129 Milano, Italy

On April 20, 1983, San Marino amateurs changed their prefix. The new one is T77. You will also have the possibility to work them with a T71 prefix that will be released only during contests and through the club station, T7ØA.

The Yaesu FT-980 has been released for the Italian market; the price should be around $2400. If you are interested in buying something here, some of the most common prices in the market are: TS-930—$2200, TH7DXX—$550, 3-500Z—$145, KLM 34XA—$750, and *Callbooks*—$60. Luckily for us, our salaries are generally lower than the American ones. Otherwise we could end up buying too many rigs!

In Italy, the new WARC bands have not yet been released, though we do hope to get them shortly. Some of us have been authorized to use 160 meters during contests in 1982/83, but now this frequency is again completely off limits. We do not have even 50 and 220 MHz, and as a result, the 2-meter band is incredibly crowded (only two MHz are used, from 144 to 146).

Repeaters are working in the 145.500/145.800 segment, with a 600-kHz split. The 432-MHz frequency is starting to become quite common, and repeaters are starting to be installed in the main cities.

We have two classes of licenses, a VHF one that does not require any code proficiency test and allows you to use 144 MHz and up with a maximum input power of 10 W, and an HF class with a code proficiency test of 8 wpm which permits use of all frequencies with a maximum input power of 300 W. As a result of the easiness to obtain the first license, there is a lot of activity in the VHF sector. To give you an idea, here are some of the distance records of the local VHFers on 144 MHz: I4EAT, 7788 km, using F2 propagation, IØAKP, 3628 km, using sporadic E, and I4EAT, 2500 km, using meteor scatter.

I4EAT has a personal record of 57 countries worked, and 22 other hams have obtained more than 20 countries.

A recent announcement has been made about the discovery of a new elementary particle. It is called the W particle. The discovery has been made in Geneva by a team of 134 European and American scientists headed by an Italian. Many other Italians participated in this W particle project; a major position is held by Giorgio Goggi I2KMG from Pavia, a city close to Milano. I2KMG has just been credited with his country 342/318, thanks to the BY1PK card that was his last missing one, and that places him in the first position on the DXCC Honor Roll.

It's amazing to discover that I2KMG has been able to perform such an impressive achievement on the air and in the lab considering also that his QRL is more than 200 miles from his QTH and that he can devote time to DX only during the weekends.

Of the new particles, it has been said that it is not yet 100% proven they really are Ws, but that they "walk like Ws and talk like Ws"; let's hope they will not make too much QRM during pileups!

A new award was introduced in March by the Italian Amateur Association (ARI), the Italian Islands Award. To obtain the award, you must reach 10 points contacting different islands (or the same one on different bands). Full details on this award and others will be made available to you in the future in this column. If you have a particular interest in Italian awards, write to: Award Manager, ARI, Via Scarlatti 31, 20124 Milano, Italy.

During the first quarter of 1983, most of the interest of active hams in this country was devoted to the various contests—in particular, the 73 40- and 80-meter contest, the ARRL DX contest, and the WPX. Big guns participate in them, fighting for the first positions, and small fishes take advantage of the situation to hunt for new states or for new prefixes.

This year, propagation has not been too good on the higher bands, but good openings have been found on 40 and 80; W6s and W7s have been worked easily without too much power or big antennas. Good scores have been claimed and some records surely will be broken.

Other records are: on 432 MHz, IØMNI with 1520 km; on 1296 MHz, IØSVS with 1520 km; on 2304 MHz, I1PE with 267 km; on 5670 MHz, I1RIP with 183 km; on 10 GHz, IØSNY with 1166 km; and on 24 GHz, I3SOY with 73 km.

ANTARCTICA SP 90 THE WORLD'S LAST FRONTIER

ANTARCTICA

Harry A. Mills W4FD

Dry Branch GA 31020

Gene Brizendine W4ATE
600 Hummingbird Dr. SE
Huntsville AL 35803

Brian Combs KA3JXR/KC4 contacted us in mid-October, 1982, seeking a high-performance, low-angle antenna suitable for long-haul amateur communications at the South Pole. Happily, the Controlled-Current Distribution antenna, (see Refs. 1,2,3), which has been in continual development by W4FD since 1959, amply fills these requirements.

Excitement ran rampant among the three of us, because Brian would have an outstanding antenna, and our CCD would be in the spotlight for the world to see what it can do.

Since Brian's scheduled departure time was October 25, W4FD immediately began the assembly of three CCD dipoles, for 7, 14, and 21 MHz. Each was of very rugged construction, necessary to endure the load of the incessant west wind, massive snowstorms, and temperatures which plunge to 100° F below zero.

Siple Station is located at the base of

the Antarctic Peninsula at 75°55' S, 83°W on ice and over 4000 feet above sea level. Since the ice is salt-free, it provides a really tall antenna-supporting insulator.

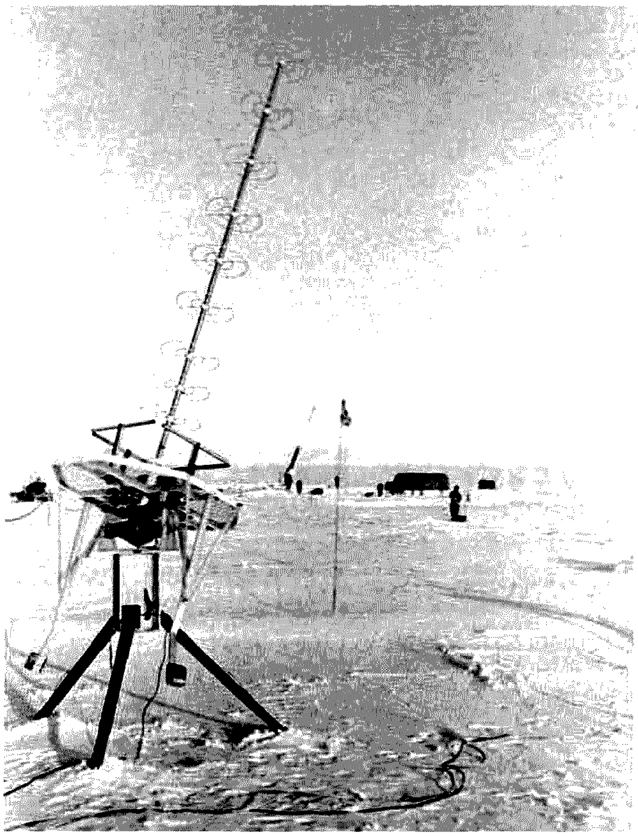
Here, the National Science Foundation will continue to investigate the response of the Earth's magnetosphere to the injection of coherent ultra-low-frequency (ULF) waves in the 2-3-kilohertz range. This response includes wave growth, spectral broadening, development of sidebands, triggering of ULF emissions, wave coupling, and particle scattering. The existing doublet for injecting the ULF waves lies on top of the accumulated snow and is 13 miles (21.4 kilometers) long. During the present Austral summer, the enormous antenna will be raised above the surface and its length doubled.

During 1983, transmissions will be made to such satellites as the Dynamics Explorer-1, the ISIS-1, and the ISIS-2 and to support the SEEP (Stimulated Emission of Energetic Particles) experiment. This is an extremely brief glimpse of the Antarctic investigations under the direction of scientists at Stanford University, the University of Minnesota, the University of New Hampshire, Bell Telephone Laboratories, and Utah State University, in cooperation with the British Antarctic Survey.

Brian KA3JXR/KC4 is age 32, married, and the son of a minister. He has a great interest in QRP operating, the outdoors, and boating. On October 26, he departed California for New Zealand, for fitting of winter clothing. He then went to McMurdo Base to await weather suitable for a safe landing at Siple Station.

Until about the end of January, mail service is through FPO, San Francisco, New Zealand, and McMurdo Base. From there it is distributed to Siple and South Pole Stations by C-130 aircraft.

Brian writes (Nov. 30): "We have now gone over a week without mail or any planes. However, life here is not hard. We are warm and comfortable, with plenty of food, which is all that anyone could ask. During the Austral summer months, we may have as many as 40 people at the station, doing various construction projects, the major one being to extend the ULF dipole to 26 miles. By the end of January, only eight of us who are staying for the winter will be left, to keep the station running on our own without outside help.



The P-Band antenna at Siple Station, Antarctica, is used to receive data from Nike-Tomahawk rockets launched into the magnetosphere (US Navy photograph).

"I am looking forward to using the three CCD antennas. I expect to be on the bands regularly; also, other members of the station will be using the equipment, so the overall use should be quite high, because there will be no mail until November, 1983. The CCD antennas also sound just right for my QRP operations on CW around 21.170 MHz, beginning around the end of December.

"We have plenty of coax and fittings of all sizes that we will likely need.

"During the present heavy work schedule, several plans for amateur construction are being considered. The problem is that the conduit carrying the coaxial transmission lines to the tower is under 40 feet of snow. The major idea at present is to utilize the aurora hut for a shack, where we would install a Collins KWM-2 and the HW-8. This plan gives a reasonable overground run to the tower. A patch board would be constructed, to mix and match equipment.

"Due to commercial schedules, we are not able to meet the Sunday and Wednesday schedules originally planned for amateur operating. We do come up a couple of times per week, after 2000 hours our time, on the Maritime Mobile net on 14.313 MHz SSB (catch us there for any traffic). All our linears are one kilowatt. I had not heard that 10 MHz had opened up. We will try to find a crystal for that band.

"We did not expect the 7-MHz CCD antenna which you provided; it should make life very interesting, indeed. Forty meters doesn't really open up for us until sunset begins. This 24 hours of daylight is quite hard on communications. Twenty meters is our best band by far. It is the only one that we can count on. Several hams have asked me on the air about the CCD antenna; they all want to learn more about it. It should be an interesting year!

"I have had my first experience with a pileup! For a newly-licensed ham who is still trying to master the basics (like moving from a net and finding the other station), a pileup is quite something. When it happened, I had to shut down before giving every station a QSO. Patience seems to be the key to keeping everything reasonably under control (perhaps some Valium wouldn't be a bad idea, either). Perhaps I could work more stations if I only gave RST reports. But I don't think that is fair, so I spend some time with every QSO.

"I expect to use off-duty time for studying to fill the gaps in my knowledge, so that I can take the commercial examination for radio telegraphy and maritime endorsements and the exam for the amateur Extra.

"The weather so far has been remarkably good. We have gone 9 days with clear sunny skies. But very soon we will be getting 5-6-day snows and winds. That is the "whiteout" that you have heard of, when you often can't see more than a few feet in front of you; still, there is work out there to be done. The Antarctic is easily one of the most beautiful places that I have been. The work is hard and often long, but we are getting a lot done."

The zero humidity in Antarctica results in violent lightning and atmospheric disturbances, as well as auroral effects, which subject antennas to many-thousand-volt stresses. For this reason, drain resistors were installed across the capacitors in the largest (7-MHz) CCD dipole. The heavy wind loading is a major structural consideration which was met by assembling each antenna on a length of 500-pound-test monofilament fishing line as a supporting messenger. Two 300-pound-test monofilament lines were then spiralled around the entire length of the antenna, in opposite directions, with frequent ties. Survival of the antennas now depends upon the monofilament lines remaining flexible and not crystalizing in the extreme sub-zero temperatures. Ends of the 500-pound-test messenger lines extend beyond the antenna ends to serve as insulators and also to provide a means for anchoring.

Ideally, the CCD dipole is fed by 300- or 450-Ohm transmission line through a 1:4 balun located directly at the transmitter output. This provides the best current balance and bandwidth, and band-changing is then only a matter of turning the transmitter bandswitch. No matching network or tuner is needed. However, at Siple, the violent winds dictated the use of coaxial line, which has a better chance for survival than even the heavy commercial-size twinlead-line types. Also, the antenna tower being over 100 feet away, a considerable run of line is exposed to possible damage by nature's elements.

The call KC3AAD will be used by another staff member at Siple Station. Phone patches to families and friends will be made on 14 and 21 MHz and have first priority. Brian asks only that callers wait until these are cleared, then general contacts on SSB and CW are welcomed. The most reliable band in the Antarctic has been 14 MHz, so more activity is expected there. All contacts will be confirmed by Brian's QSL upon his arrival home following the 15-month tour.

A CCD antenna net was recently formed by a group of enthusiastic users in the Oklahoma area. Anyone interested in a better antenna is invited to join N6ATS and the group on 7.203 MHz (3.843 MHz, alternate) at 0100 UTC daily.

For construction data for the improved CCD, send an SASE to either of the authors.

Laramie WY 82070

If anyone can supply me with the manual and schematic for a Lafayette HE-89 vfo, I will pay for the copying and postage.

Greg Dickerson N4OBS
12453 Northwood Rd.
Savannah GA 31406

I am compiling a list of access codes for repeaters, and I need input from *73*'s readers. Access codes for open autopatches will be listed with permission; access codes for closed (member-only) autopatches will not, but information about how to join will be included. Also, please indicate repeater power, antenna height, coverage, and autopatch exchange. Lists will be sent to all who contribute, and others may receive it for an SASE and copying costs. I would also like to hear from others in the EMS and forensic medicine fields (I am a CEMT and Deputy Coroner).

Down-Under Depth Sounder

Get your feet wet with this Australian construction project. We promise that you won't get in over your head.

Reprinted with permission from the November, 1982, issue of *Electronics Australia*, PO Box 163, Chippendale, 2008, NSW Australia.

Depth sounders on pleasure craft are primarily used for simply measuring water depth, although some more elaborate (and expensive) models can locate fish or even produce a scan of the sea bottom so that reefs and other sunken objects can be located. The unit described here falls into the former category and, as such, is designed to be easy to construct and to operate.

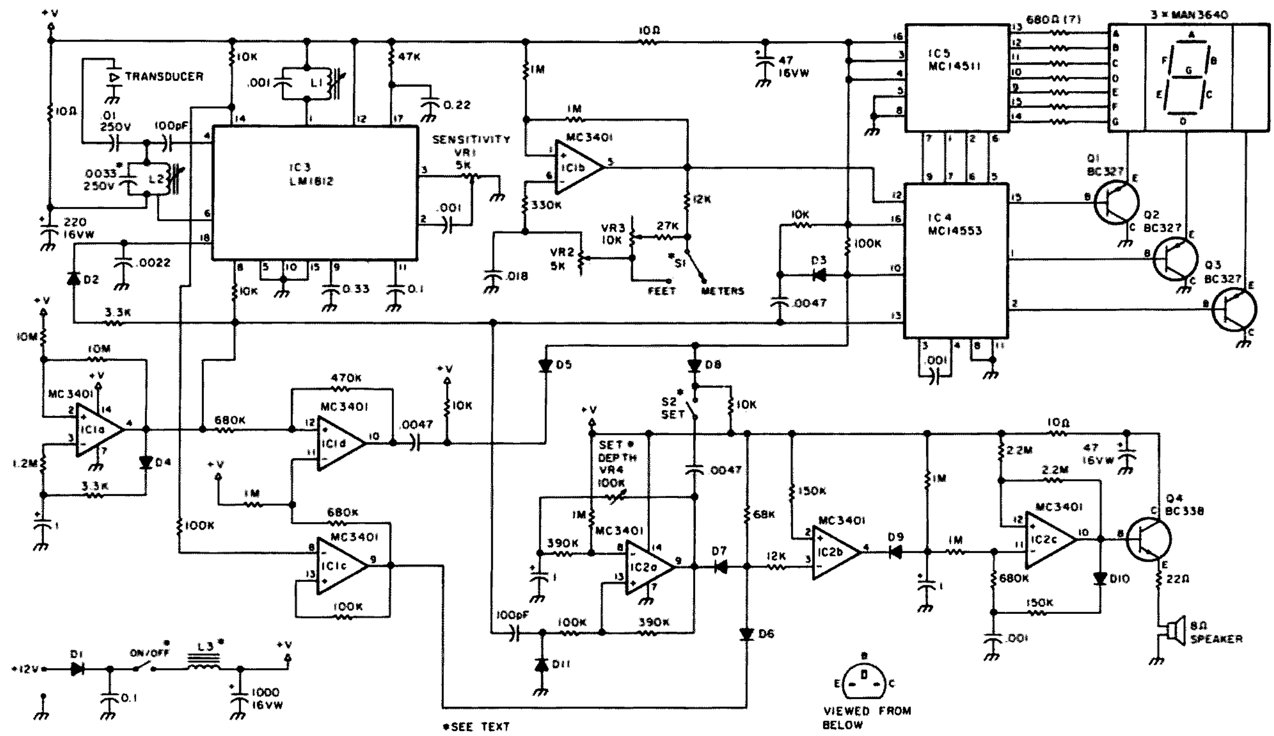
After all, what could be easier than reading a few numbers off a digital display?

The circuit was developed by Sydney engineer Neville Harleck whose company, Monitor Instruments, can supply complete kits for the project. We at *Electronics Australia* simply assembled the unit depicted here and prepared the constructional details.

Once assembled, the kit certainly looks the part. Two printed circuit boards—a display board and a main board—accommodate virtually all the electronics, and these are housed in a white molded plastic case. Overall case dimensions are a compact 125 mm W × 140 mm D × 58 mm H.

While the case is not watertight, it is reasonably weatherproof and should stand up well to the rigors of the marine environment. Its compact size also means that you should have no difficulty in finding a suitable mounting position for the device regardless of the type of boat you own.

Photo A. The digital depth sounder.



Circuit diagram for the digital depth sounder.

Other features include a bright 3-digit LED display, a sensitivity control, an alarm-depth-set control, and a feet/meters switch mounted on the rear panel. A U-shaped mounting bracket allows the case to be tilted to provide a convenient viewing angle.

The audible alarm function is a particularly useful feature. When selected, it sounds whenever the water depth decreases below a preset level, thus eliminating the need for continuous visual monitoring. The danger of running aground is never greater than when the fish are biting, or you are otherwise preoccupied!

Basic Principle

The principle on which a depth sounder operates is quite straightforward. An ultrasonic sound pulse is directed into the water and the time taken for the signal to be reflected from the bottom is measured. Since the speed of sound in water is reasonably constant, the distance the sound pulse has traveled, and hence the water depth, can be easily calculated. Fig. 1 shows the essential elements of a depth-sounder system.

First, the transmitter generates a short pulse of 200-kHz energy and, at the same time, starts the clock. The receiver subsequently detects the reflected signal and produces a pulse that stops the clock. If the clock is counting at the correct rate, then the display will indicate the water depth directly in the appropriate units (meters or feet).

Most of the important functions of the transmitter and receiver circuits are incorporated into a single IC made by National Semiconductor. This IC, designated the LM1812, has been around for some years now and greatly simplifies the design task for a practical depth sounder. Fig. 2 shows the block diagram of the complete unit and should be studied in conjunction with the circuit diagram in order to understand how the instrument operates.

Circuit Description

Our circuit description starts with IC1a, which functions as the timebase clock. This generates a 1-ms pulse approximately every 800 ms. This pulse activates the transmitter and resets the display and alarm functions.

IC1a, part of an MC3401 quad op amp, is wired as an astable multivibrator which

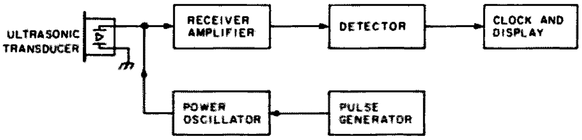


Fig. 1. Basic scheme for an ultrasonic depth-sounder circuit.

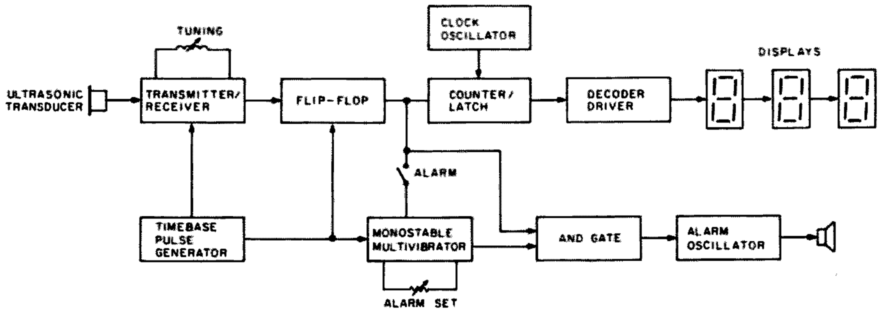

Fig. 2. Block diagram of the complete depth-sounder circuit. The transmitter/receiver is based on a single IC.

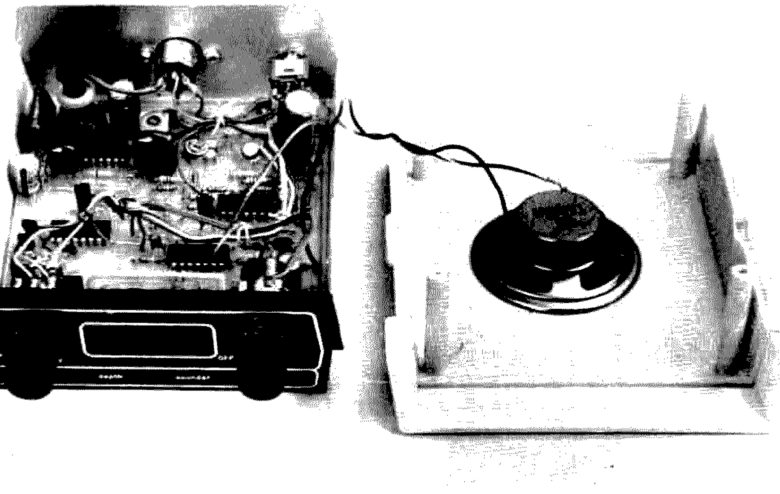

Photo B. Virtually all the circuitry is accommodated on two PC boards.

functions as follows: At switch-on, both the non-inverting input (pin 2) and the output (pin 4) are high. The 1-μF timing capacitor now charges via diode D4 and its series 3.3k-Ω resistor. When the voltage across the capacitor (and hence on pin 3 of IC1a) reaches a critical level, the output of IC1a goes low.

Since diode D4 is now reverse biased, the timing capacitor discharges via the 1.2-megohm resistor into pin 3 of IC1a. When the voltage on pin 3 goes low enough, pin 4 switches high again and the whole cycle is repeated. The 10-megohm resistor between pins 2 and 4 provides positive feedback to speed up the switching transitions.

The output of IC1a thus consists of a train of short positive-going pulses. These pulses are coupled to ultrasonic transceiver IC3, counter IC4, and to the non-inverting input of IC2a which controls the alarm function.

IC3 is the LM1812 transceiver chip referred to earlier. Both the transmitter and receiver sections share a common tuned circuit, consisting of L1 and the .001-μF capacitor, which makes for easy tuning. Readers are referred to the *National Semiconductor Linear Databook* for a detailed description of this IC, as only a general description of its operation will be given here.

The timebase pulse from IC1a is applied to pin 8 of IC3 via a 10k-Ω resistor. This causes the transmitter to "fire" at a frequency determined by the tuned circuit, the output signal appearing at pin 6. This is coupled to the transducer via L2, a parallel 3300-pF capacitor, and a .01-μF blocking capacitor. The signal appearing across the transducer thus consists of a 1-ms burst of 200-kHz energy of about 150-200 V peak-to-peak. At the end of the 1-ms clock pulse, IC3 reverts to the receive mode.

Signals picked up by the transducer are coupled into the first receiver stage at pin 4 via a 100-pF capacitor. Following amplification, the signal appears at pin 3 and is coupled into the next amplifier stage via VR1, the sensitivity control. It is this stage that is tuned by the LC network on pin 1.

As far as the user is concerned, the signal is not seen again until it appears at pin 14, and by this time it has been amplified, detected, shaped, clamped, and clipped so that we get a nice clean negative-going pulse from the supply voltage to ground.

The functions of a few other pins on IC3 should also be considered before moving on to the next section. It will be noticed that the timebase pulse is also fed into pin 18 via a 3.3k-Ω resistor and series diode D2. This is done to inhibit the detector during the transmit time and thus prevent a false output signal appearing at pin 14. The 47k-Ω resistor and 0.22-μF capacitor connected to pin 17 provide a measure of impulse noise rejection.

The 0.33-μF capacitor on pin 9 is charged during the transmit period and serves to inhibit the second stage of the receiver. As the

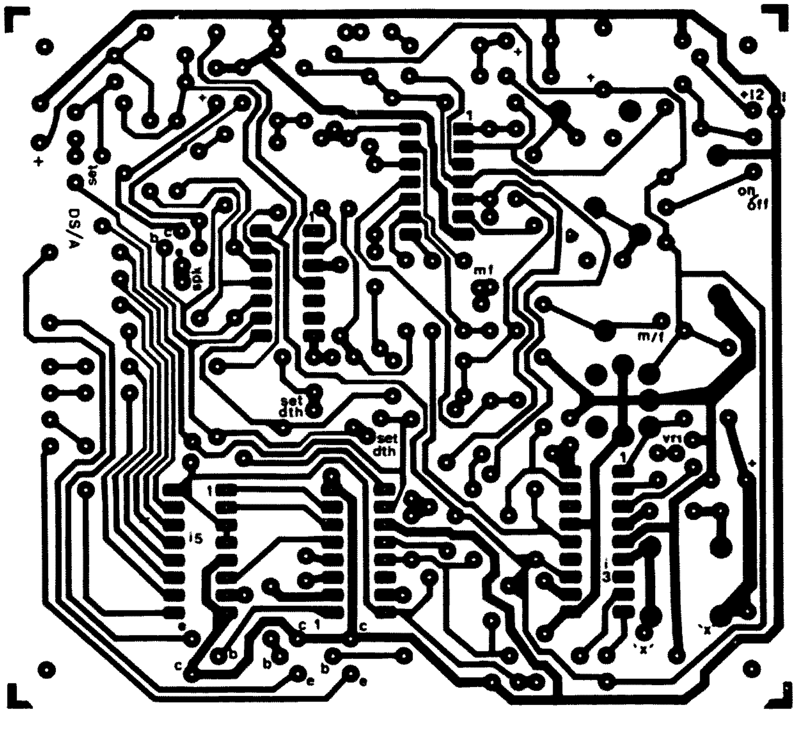

Fig. 3. PC board for the depth sounder.

voltage across the capacitor falls (at the end of the transmit period), the gain of the second stage increases. This has the effect of filtering out signals received during the first few milliseconds after the transmit pulse. Without this effect, echoes from the boat's keel or rudder could falsely trigger the display circuitry and cause an incorrect reading.

The output signal appearing at pin 14 is coupled to IC1c which functions simply as an inverter. The inverted signal is then fed to IC1d which is connected as a monostable and functions as follows.

Pins 9 and 4 of IC1 are normally low and, because of its 470k-Ω feedback resistor, IC1d will be latched either high or low. When a timebase pulse occurs, pins 12 and 10 are forced high, and the feedback resistor latches the device in this state. When an echo is subsequently received, it produces a positive pulse at pin 9 which is coupled to the inverting input of IC1d and hence forces pin 10 to go low.

Thus, the time that pin 10 stays high is the time from transmit pulse to received echo. Note that pin 10 stays low until the next transmit pulse, which means that any echoes occurring after the first have no further effect on IC1d. Multiple echoes are thus ignored.

The signal at pin 10 of IC1d is differentiated and the negative-going pulse coupled via diode D5 to the latch-enable input (pin 10) of counter IC4.

IC4 is an MC14553 3-digit BCD counter with multiplexed outputs. The counter is reset to zero by the timebase pulse on pin 13 and the trailing edge of this pulse is used to enable the latches in the chip (thus displaying 000); i.e., the timebase pulse is differentiated by a .0047-µF capacitor and a 10k-Ω resistor and the resultant negative-going pulse coupled to the latch-enable input of IC4 via D3.

As soon as the reset pulse has finished, the counter starts counting clock pulses from IC1b. When an echo is received, a negative-going pulse is coupled through to pin 10 via diode D5 as above, and the counter data is transferred to the latches for decoding and display. The next transmit pulse again resets the counter and displays to zero and the cycle is repeated.

Note that if no echo is received, the displays will remain on zero. This is because a latch-enable pulse must occur before data can be transferred to the latches.

IC5 is a BCD-to-7-segment decoder/driver chip which decodes the binary data from IC4 to drive common cathode 7-segment LED displays. Since the displays are multiplexed, the corresponding anodes are wired in parallel and connected to the outputs of IC5 via 680-Ohm current-limiting resistors. Each display cathode is connected to the emitter of a BC327 PNP transistor (Q1, Q2, and Q3), and these transistors are turned on and off by signals from the multiplexer in IC4.

If you like, you can regard the counter, decoder, and display circuitry as a "black box" controlled solely by the timebase pulse, the latch-enable pulses, and the clock pulses on pins 13, 10, and 12 of IC4 respectively.

Clock pulses for IC4 are derived from IC1b which is connected as a multivibrator and runs continuously. Its frequency is controlled by the .018-µF capacitor in company with VR2, VR3, and the 27k-Ω and 12k-Ω feedback resistors. Switch S1 shorts out VR3 and the 27k-Ω resistor, thus changing the oscillator frequency so that the display can read directly in either feet or meters.

The clock frequencies for IC1b are derived as follows: The speed of sound in water is approximately 1500 m/s and is fairly constant over

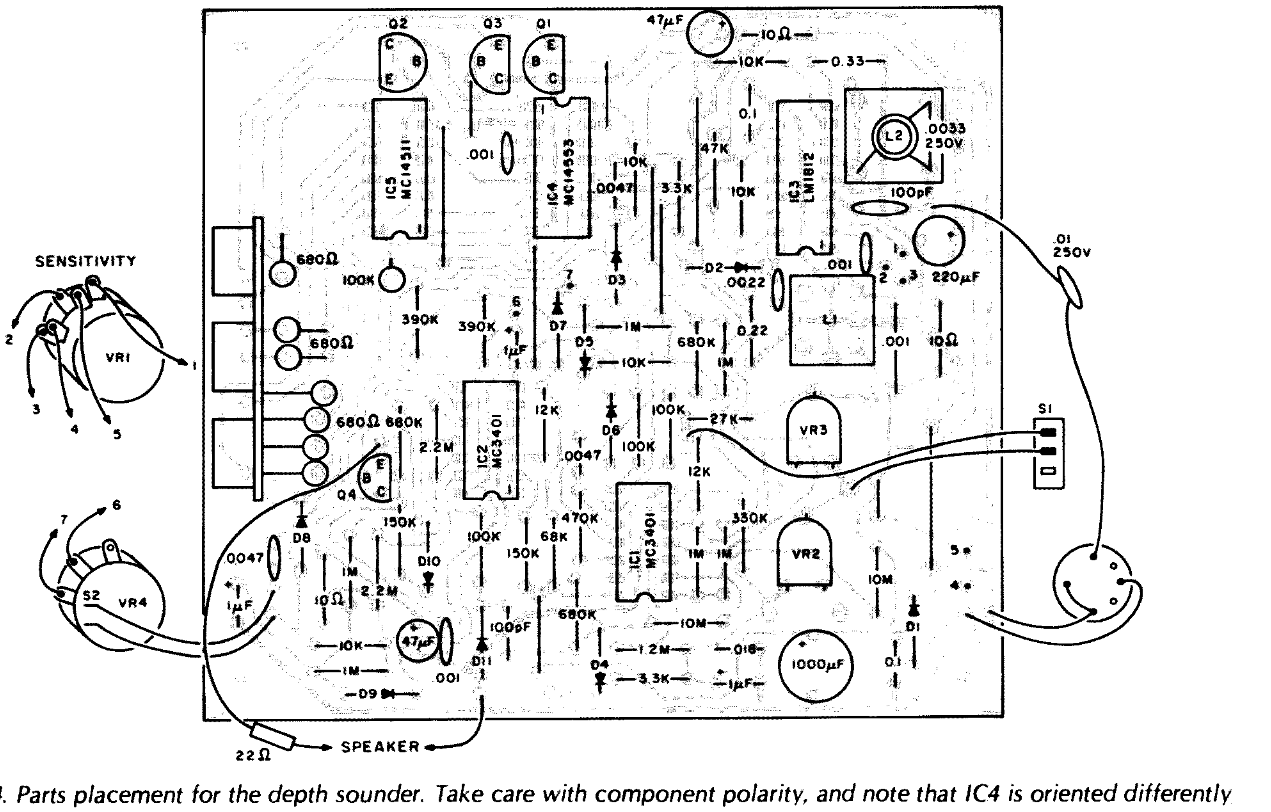

Fig. 4. Parts placement for the depth sounder. Take care with component polarity, and note that IC4 is oriented differently than the other ICs.

quite a wide range of temperature and salinity. It will therefore take 1 second to receive an echo in 750 meters of water, since the sound pulse has to go down and up. Thus, if the clock is set to 750 pulses per second, the counter will count up to 750 and the water depth will be displayed directly in meters.

If we want the display to read in feet, then the oscillator frequency can be found simply by multiplying 750 by 3.28 (the conversion factor from meters to feet), which gives 2460 Hz. Thus, the clock must run at 2460 Hz for feet and 750 Hz for meters. A fathoms display could be achieved with a clock of 2460/6 = 410 Hz.

Finally, we come to the alarm function. The depth at which the alarm sounds is set using front-panel alarm-set control VR4. First, the alarm-set control is pulled out to display the alarm setting. The control is then rotated until the display reads the required alarm depth and then pushed in again. The display immediately reverts to the water depth and, if this is less than the alarm setting, an audible warning is produced.

All alarm functions are controlled by IC2, an MC3401 quad op amp. IC2a functions as a monostable multivibrator, the period of which is determined by VR4 and the 1-µF timing capacitor. The monostable is triggered by the timebase pulse which is coupled in via a 100-pF capacitor and causes pin 9 to go high, thus reverse biasing diode D7.

If an echo is received while the monostable output is high, then both D6 and D7 will be reverse biased for the duration of the echo pulse (i.e., for as long as pin 9 of IC1c remains high). This causes pin 3 of IC2b to go high and the pin 4 output to go low. Since it is now forward biased, the anode of diode D9 also goes low, enabling oscillator IC2c to start up.

IC2c is a voltage-controlled oscillator whose frequency depends on the voltage at the anode of D9, i.e., the charge on the 1-µF capacitor. Initially, the 1-µF capacitor is discharged and the oscillator starts at a high frequency. When the echo pulse ends, D9 is reverse biased again and the 1-µF capacitor charges towards the positive supply rail via a 1-megohm resistor. As the voltage across this capacitor rises, the discharge current from the .001-µF capacitor slows and the output frequency drops lower and lower until eventually the oscillator stops.

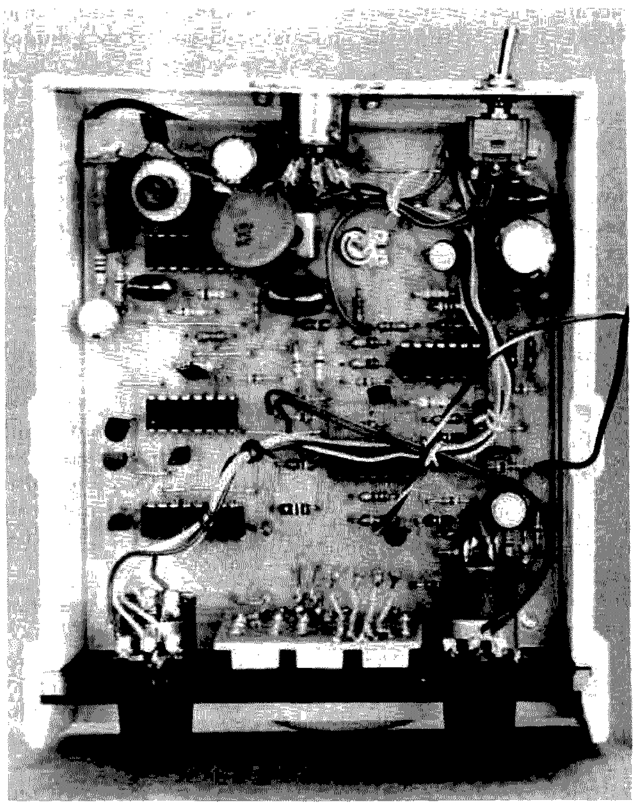

Photo C. Close-up view of the completed PCB assembly. Note that the seven 680-Ohm resistors adjacent to the display board are mounted end on.

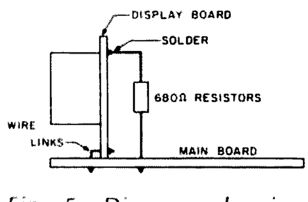

Fig. 5. Diagram showing how four of the 680-Ohm resistors are mounted.

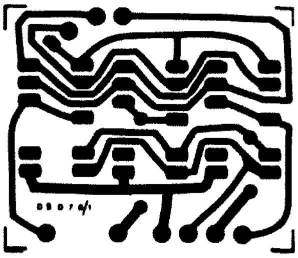

Fig. 6. PC board for the display.

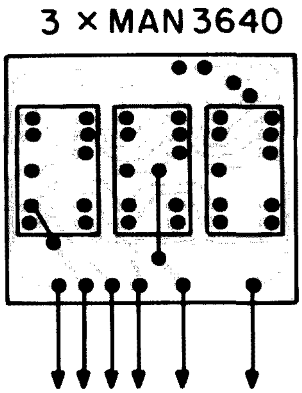

Fig. 7. Parts placement for the display PCB.

NPN transistor Q4 simply functions as a buffer and drives a small loudspeaker in its emitter circuit via a 22-Ohm resistor. The result is a siren-like note pulsed at the timebase frequency.

The alarm can sound only if an echo pulse is received while the output of monostable IC2a is high. Thus, it is the monostable pulse width that determines the alarm depth and this is displayed by using the trailing edge of the pulse to trigger the latch enable (pin 10) of counter IC4.

First, however, the echo pulse must be disabled, and this is done by setting the sensitivity control (VR1) to minimum. The output of monostable IC2a is differentiated by the .0047-µF capacitor and the negative-going pulse produced at the trailing edge coupled via switch S2 (on the back of VR4) and diode D8 to the latch enable of IC4. Since the timebase simultaneously resets IC4 and enables IC2a, the display will now show the alarm depth in the appropriate units.

Power for the circuit is derived from a 12-V battery (normally fitted to the boat). Diode D1 provides protection against reversed supply polarity, while 0.1-µF and 1000-µF capacitors provide supply decoupling and filtering. Choke L3 is not supplied as part of the kit and is not fitted unless problems are encountered with ignition interference (see Construction).

Construction

Construction can begin with the assembly of the main PCB according to the overlay diagram. Insert the wire links first, followed by the resistors, capacitors, coils, diodes, and transistors. Take care to ensure that all polarized components are mounted the right way round.

The ICs should be inserted last. Note that IC4 and IC5 are CMOS devices and

should be treated accordingly. When soldering these devices, ground the barrel of your soldering iron to the ground track on the PCB (use a small clip lead) and solder the supply pins (8 and 16) last.

The display PCB should be assembled next. Watch the orientation of the displays and note that the links must go in first. The display board is mounted on the main board using six tinned copper-wire links along the bottom edge. In addition, four of the 680-Ohm current-limiting resistors are mounted between the main PCB and the display PCB and, if these are bent as shown in Fig. 3, will provide additional support.

The front-panel controls can now be mounted in position and the red perspex window cemented in place using epoxy adhesive. This done, wire the controls to the main PCB and fit the DIN socket and feet/meters switch to the rear panel.

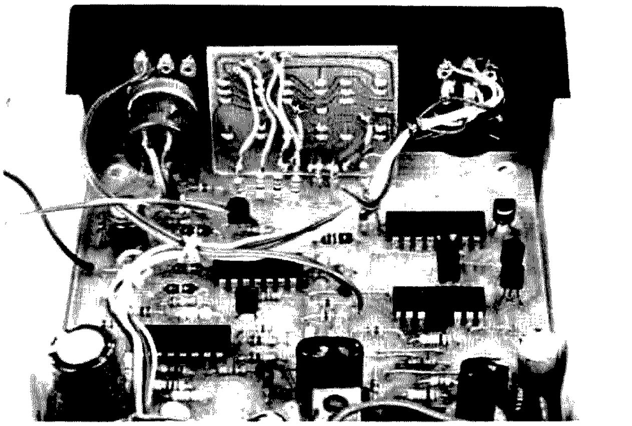

Photo D. Front panel and display PCB details. Note that the spare switch pole on the alarm-set control can be used to automatically disable the echo pulse (see text).

Complete the wiring according to the main wiring diagram and Fig. 3.

Although not part of the original design, the circuit can be easily modified so that the echo signal is automatically disabled whenever S2 is closed. As supplied, there is a spare switch pole on the back of VR4, and this may be used to disable the echo signal by connecting it between pin 2 of IC3 and ground. With this simple modification, you won't have to fiddle with the sensitivity control each time you wish to display the alarm depth.

The loudspeaker is fitted to the top half of the case (over the slots) by gluing it in place with contact adhesive. A piece of cloth is provided to cover the slots. Connect up the speaker, fit the transducer DIN plug with a couple of flying leads for the power connections, and you are ready for the smoke test!

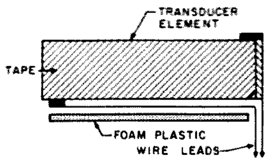
Apply power (12 V) and switch on. All being well, you should be greeted by a chirp from the speaker and the display should read 000 or 001. Make sure that the alarm-set control is pushed in and fully anticlockwise (i.e., alarm off).

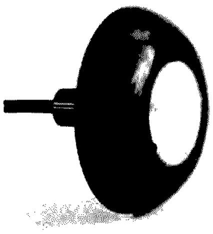
Now set the sensitivity control to minimum (to disable the echo pulse) and pull out the alarm-set control. Slowly rotate the alarm-set control clockwise and check that the display shows progressively higher numbers. If this check is OK, operate the feet/meters switch and check that the display changes by a 3:1 ratio. With the alarm-set control fully clockwise, the display should read a maximum of approximately 30

TRANSDUCER ASSEMBLY

Begin the transducer assembly by gluing together the two plastic pieces forming the element housing. These are molded in ABS, so use a suitable styrene adhesive. Apply adhesive sparingly to the top edges of the "fried-egg"-shaped piece and then press the two parts together, ensuring that the mounting holes are correctly aligned. Allow sufficient time for the adhesive to dry.

The barium titanate element must be prepared next. Carefully tin a small spot close to the edge of the element on each side and solder a short length of hookup wire to each spot. Be very careful with this operation, as too much heat will burn the silver off the surface of the element. Wrap the circumference of the element in plastic tape, using the tape to hold one of the wires against the edge.





The surface where the two wires emerge is now the rear face of the transducer. Now lay the wire from the rear surface against the transducer and place the plastic foam disc in position. Use more tape to secure it in place. The two wires should now emerge from one side as shown and should be reasonably well supported by the tape. Leave about 25 mm of wire free and strip and tin 3 mm at the end of each wire.

Force one end of the coaxial cable through the hole in the stem of the housing and strip and tin the ends of the braid and the center conductor. Carefully solder the coax to the wires coming out of the transducer assembly and insulate the joints with more plastic tape.

The transducer assembly must now be pushed into the housing, carefully pulling the coax down to avoid building up a loop of cable behind the transducer.

Push the transducer down in the housing so that its front surface is about 3 mm below the lip of the housing cavity. Check the cable at the other end for shorts; if all is well, put your meter on a low ac voltage range and tap the transducer with a screwdriver handle. You should see the meter give a kick, indicating that the transducer is functioning correctly. If not, check your connections carefully.

Support the transducer assembly face up, where it can be left overnight, and you are ready for the epoxy resin encapsulation. Do not use 5-minute epoxy. You must obtain some epoxy resin with a 6–12-hour setting time and carefully mix up enough to fill the transducer housing. After mixing, allow it to stand for about 20 minutes to allow the air bubbles to escape, then pour it into the transducer housing.

Fill the housing right to the top so that the transducer element is completely immersed and keep an eye on it for an hour or so, topping it as it runs down behind the element. Use a pin to prick any air bubbles that emerge. Take care here, as any air bubbles can drastically degrade transducer performance.

On no account should you use polyester resin—you must use epoxy. Epiglass 40 resin is quite satisfactory.

Finally, fit the DIN plug to the end of the cable, and fit the red and black supply leads.

meters (VR2 and VR3 roughly midrange).

Now turn the alarm off and the display should go back to zero. Turn the sensitivity control fully clockwise and lightly tap the face of the transducer with a screwdriver handle. The display should flicker and momentarily read some random numbers. If the alarm is now set to maximum depth, it may be possible to trigger it by tapping the transducer face as above. (It will trigger only if you "hit" upon an echo reading of less than the alarm setting.)

Calibration

If all the above tests work, your depth sounder is functioning and will give readings if taken out in a boat. However, it has to be tuned and calibrated if we are to obtain maximum sensitivity and if the readings are to be accurate. If you have access to the appropriate test gear, this can be done easily on the bench; if you don't have test gear, the only way is to take the instrument out on the water.

Assuming that you don't have test gear, the procedure is as follows:

● *Tuning.* Advance the sensitivity control until an echo is obtained, then back it off until the echo is just lost. Now tune L1 carefully until the echo reappears (display reading). Reduce the sensitivity again and continue the process until the optimum setting is found for L1. L2 can be tuned in the same way, but as this has a low Q, its setting is not so critical. Most units will tune with the slug of L2 about flush with the top of the former.

● *Calibration.* Once the tuning is done, the calibration can be set if you have a chart. The problem is to find a known depth of water and set VR2 and VR3 to the known depth. Do not forget to allow for the fact that the transducer may not be at the surface if it is mounted on the bottom of the boat; i.e., the instrument reads depth beneath the transducer.

It may even be possible to resort to the good old lead line to get an accurate depth measurement.

First, set switch S1 to the feet position and adjust trimpot VR2 until the display shows the correct depth. This done, set S1 to meters and adjust trimpot VR3. Note that VR2 must be set first as it affects the setting of VR3.

If you have access to an oscilloscope, a signal generator, and a frequency meter, the procedure is somewhat different:

● *Tuning.* Connect the oscilloscope probe to pin 1 of IC3 and couple in a 200-kHz signal to L2 via the .01-µF capacitor. Now adjust L1 and L2 for maximum signal strength.

If no signal generator is available, then it is possible to get a signal echo in air. Clamp the transducer to the underside of the workbench and check that the unit is over a hard floor (carpet will not reflect ultrasound). Once an echo is being received, simply tune L1 and L2 for maximum signal strength. (Note: Because of the much lower velocity of sound in air than in water, the display will read about four and a half times the actual distance.)

● *Calibration.* A frequency meter connected to pin 5 of IC1b will allow precise setting of VR2 and VR3 to 2460 Hz and 750 Hz respectively. Alternately, you can use a CRO or a frequency meter to set the periods to 406 µs and 1.333 ms respectively.

Once the unit is tuned and calibrated, it may be mounted in the case. To do this, lay the top half of the case (the half with the speaker in it) upside down on the bench and sit the circuit board on the four mounting pillars. Fit the front and back panels into the slots provided and fit the large brass nuts into the cavities in the sides. Ensure that the board holes line up with the mounting pillar holes and fit the bottom half of the case.

The two halves will fit together closely and the four 12 mm × no. 4 self-tapping screws may be fitted through the bottom holes and screwed into the mounting pillars. The U-shaped mounting bracket may now be attached with the large plastic knob-headed screws. Fit the front-panel control knobs, and your instrument is ready for use.

Operation

The transducer is the key to satisfactory operation of

Parts List

1	printed circuit board, 111 x 100 mm

Miscellaneous

Rainbow cable, tinned copper wire, solder, styrene adhesive, epoxy resin

any depth sounder, and a few tips on mounting may not go astray. Many people have mounted transducers inside the hull in a "water-box" and it is possible to get satisfactory results with this method. However, some sound attenuation will occur and this will reduce the range of the instrument. In the worst case, it may not work at all.

The best mounting method is on the outside of the hull, roughly in the middle third of the boat and as close to the center line as possible. It must be clear of any fittings and in an area of clear water flow. Turbulence and bubbles under the transducer will reduce its performance. In yachts, hull-heeling under sail will cause the transducer to fire its sound beam out at an angle and this will reduce sensitivity; if the boat heels far enough, the echo may be lost altogether. Mind you, when this happens, the crew is usually too busy to be looking at echo sounders!

Installation of the unit should be straightforward, but keep the transducer and all leads as far away from the engine as possible to avoid ignition interference. If ignition interference does prove a problem (i.e., the display reading fluctuates randomly), choke L3 will have to be fitted in place of the appropriate link on the PCB. This should be a power supply choke of around 10 mH in value.

Because this choke is not available from Monitor Instruments, it will have to be purchased separately, if required.

The maximum depth range attainable with this instrument will vary considerably and depends on a number of factors including tuning accuracy, transducer mounting, water turbulence, and bottom reflectivity. Bottom reflectivity will be high with a flat sandy bottom and may be nil with heavy weed growing over soft mud.

A typical unit should give a depth range of from 80-120 meters without any difficulty and possibly more with careful tuning and installation.

Note that apparently strange readings can occur with this type of instrument because the display is triggered by the first echo received. For example, echoes may be received from cold layers in the water, undersea currents, propeller wash from other boats, and even fish. The usual effect of this is a steady bottom reading of 30 meters, say, with occasional readings of much less, e.g., a fish at 20 meters or a salinity or cold water layer at 15 meters, etc. ■

KITS AND PARTS AVAILABLE

The sole supplier of the PCB, a proprietary design, is Monitor Instruments, PO Box 116, Rosebery, Sydney, 2018, NSW Australia. Any of the following ordered, when orders are received with payment, will be shipped within 5 days. Amounts are in US dollars.

Fully assembled and tested Depth Sounder—$180.00[1]
Complete kit (add $12.00 for postage)—$138.00
Transducer kit (add $7.00 for postage)—$40.00
Molded plastic case/mounting (add $5.00)—$25.00[2]
Set of circuit boards (add $5.00)—$20.00
Set of coils (add $5.00)—$12.50
Set of semiconductors, complete (add $5.00)—$25.00[3]

[1]Postpaid.
[2]Includes front and back panels, control knobs, and gimbal mounting bracket/knobs.
[3]Does not include the displays.

The ROM-less, RAM-less CQ Sender

Automatic CW can be yours for the price of a few diodes. And you can reprogram without spending a dime.

Morse code can be generated automatically by various methods using memory chips like RAMs, PROMs, and EPROMs. If RAMs (Random Access Memory) are used in the design, the memory is temporary. That means if the unit is switched off, all the memory contents will be blanked unless there is a standby battery connected permanently. Providing a standby battery is not economical, at least for hams.

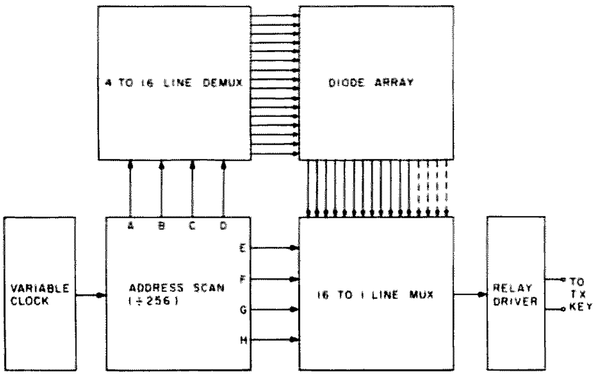

Fig. 1. Block diagram of CQ Sender.

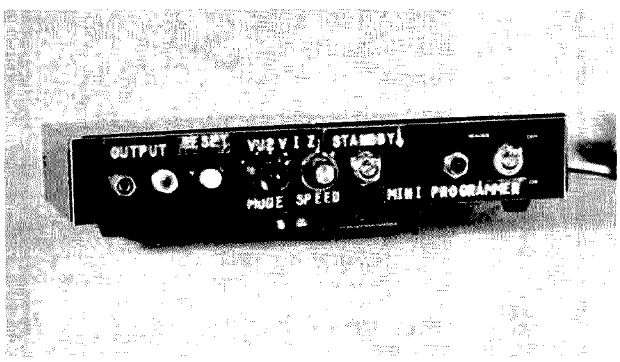


The reprogrammable automatic CQ Sender.

ROMs (Read Only Memory) are programmed by the manufacturer according to the consumer's requirement and cannot be altered once programmed. But the programming is permanent, hence does not require a standby battery.

PROMs (Programmable ROMs) are identical to ROMs except that they can be programmed by the user. The big disadvantage is that the programming cannot be altered once programmed. Hence it will become useless if the callsign of the user is changed. Moreover, PROMs require a complicated setup to program. The IC becomes useless if greatest care is not taken while programming.

One is able to program EPROMs (Erasable PROMs) any number of times. They do not require standby power to retain their memory. The contents can be erased by exposing the IC to UV lights (UVEPROMs) or by electrical energy (EEPROMs). However, for each programming, a complicated separate circuitry with different voltage supplies and UV light to erase the contents are required. Many builders do not have and cannot afford to have what is required for this. Also, the EPROMs themselves are very costly.

Keeping all this in my mind, I have designed a "CQ Sender" which is equivalent to EPROM design in operation yet uses no EPROMs, PROMs, ROMs, or RAMs. My design has got all the facilities you can get using EPROMs, yet it does not require any separate programming circuitry or the UV light for erasing the contents! At first you may think that it is not possible, but I did it!

The block diagram of "CQ Sender" is shown in Fig. 1 and the schematic diagram in Fig. 2. It consists of the following:

- Clock-pulse generator, 7400 IC
- Address scan (÷256 counter), 2×7493
- 4-line-to-16-line 74154 demultiplexer
- Diode matrix—all 1N914 diodes

●16-line-to-1-line 74150 multiplexer
●Switching transistor SL100 and relay

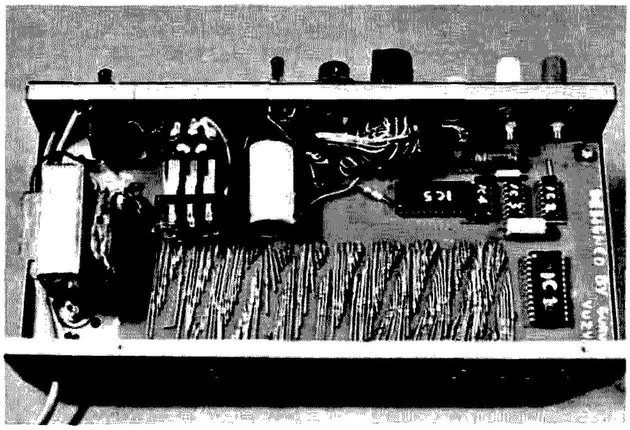
The *clock-pulse generator* is constructed using 2 inverters (a NAND is used as an inverter). The clock frequency is variable, enabling us to set the CW speed at any desired level.

The *address scan* is constructed using two cascaded 7493 chips (each ÷16 mode). An address scan is nothing but a ÷256 counter. It counts from 0 to 255 (256 states) and resets to 0 and starts counting once again. The clock output is fed to this counter's clock input. This means for every one clock pulse (falling edge) the counter advances by one count. The counter has 8-bit output lines (to represent 255 in binary form we need 8 bits), and out of these 8 lines the first 4 lines (starting from LSB) are applied to the demultiplexer IC and the remaining 4 lines to the multiplexer IC.

The *4-line-to-16-line demultiplexer* accepts a 4-bit binary output address and has 16 output lines. If a 4-bit binary output address like 0110 is applied to it, then the corresponding output line (no. 6) will go to the low level leaving all the remaining 15 output lines at high level. Since 4 output lines of the 7493 IC are fed to the "output address" of this demultiplexer, each of its output lines will go low and remain there for a duration determined by the clock frequency.

The *diode matrix:* While programming, each dot is considered as 1 unit, each dash is considered as 3 units, a character gap is 1 unit, a letter gap is 3 units, and a word gap is 5 units. Whenever a dot is required, the output from the appropriate line of the demultiplexer is taken through a diode. If a dash is required, then the outputs from 3 consecutive lines are taken through individual diodes and these diodes are bunched together. These bunches (columns) of diodes are then connected to the different input lines of the 74150 multiplexer.

Referring to the schematic diagram (Fig. 2), the first diode column consists of 8 diodes and the second column consists of 10 diodes. In the first column, the outputs of lines 2, 3, and 4 are taken to generate a dash and the output of line 5 is not taken (for 1 unit space). Then the output of line 6 is taken for a dot, while line 7 is not used (for a unit space). The outputs of lines 8, 9, and 10 are taken through diodes (for a dash), the output of line 11 is not used (for a unit space), and the output of line 12 is taken for a dot. This arrangement produces the code — · — · which is equivalent to the letter C. As per convention, a 3-unit space is given after the letter C (the outputs of lines 13, 14, and 15 are not used). In the



Interior view of the reprogrammable automatic CQ Sender.

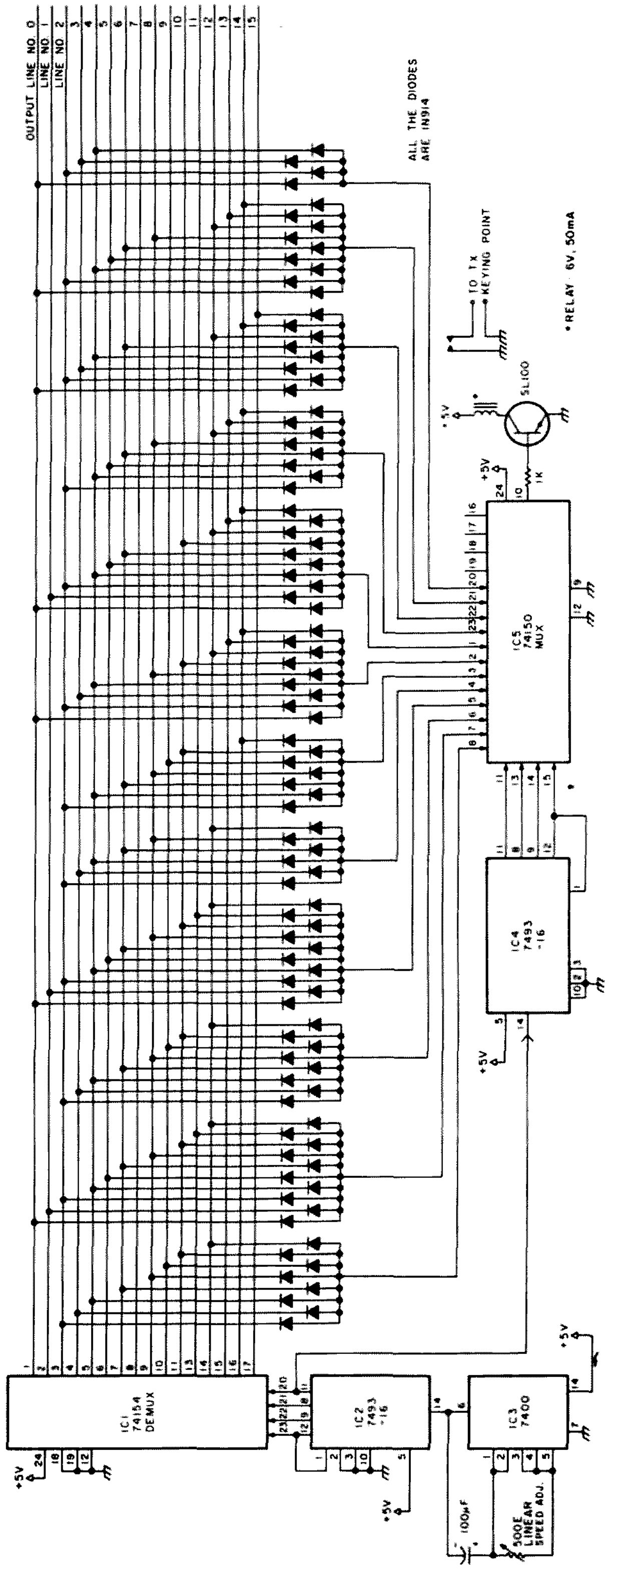


Fig. 2. Schematic diagram of the CQ Sender, programmed to call "CQ CQ DE VU2ARC $\overline{AR}$ K."

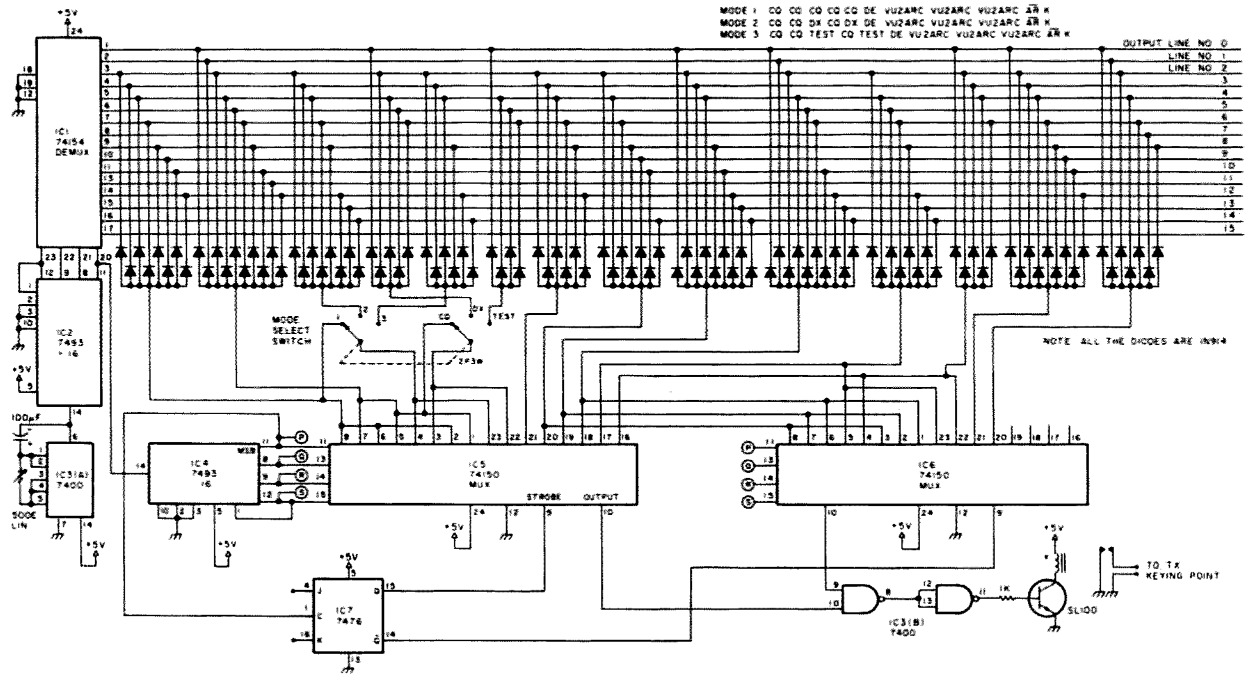

Fig. 3. Improved CQ Sender with different modes.

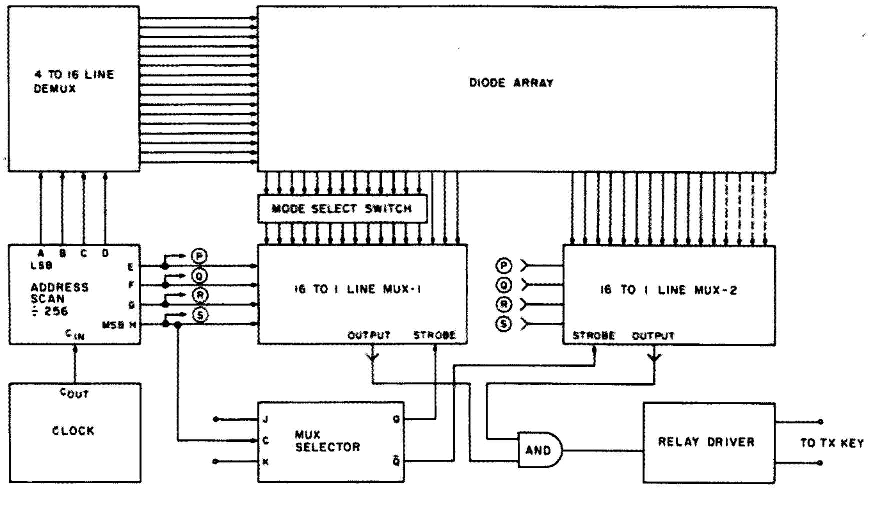

Fig. 4. Block diagram of the "improved" CQ Sender with different modes.

second column of diodes you will notice the letter Q is generated, in the third column again C (notice the 5-unit word space before this C), and in the fourth column Q is generated. In the fifth column the word DE is programmed and so on. All these columns are connected to the individual input lines of the 74150 multiplexer.

The *74150 multiplexer* has 16 data-input lines, one output line, and 4 input addresses. If a 4-bit binary code is applied to its input address, then the data-input line which is the decimal equivalent of the applied binary input address will be connected to its output line. Suppose a binary code like 1000 is applied to its input address. Then data-input line 8 would be connected to its output line (pin 10 of the 74150 IC), and during this period, whatever data is fed to this input line would be made available at its output line (after an inversion, of course). To make it simpler, this multiplexer can be considered as a single-pole, 16-way (1P16W) bandswitch. As soon as the unit is switched on, the pole will be connected to its first "way" (bandswitch in position 1) and at the end of the 16th pulse (from the clock), this bandswitch receives a command through its input address to change its position from the first band to the second band. At the end of the 32nd pulse, this bandswitch moves to the third position and so on. At the 16th position, the bandswitch remains for a 16-pulse duration, then switches back to its first band position and the cycle repeats.

The output of this multiplexer will be a continuous stream of 0s and 1s. This output will then be applied to a switching transistor, SL100. For each 1 the relay will be actuated (holds) and for a 0 the relay will not operate. The relay contacts are used to key the transceiver (alternately, a switching transistor like 2N3696 could be used).

An improved CQ Sender with different modes and an increased memory (Fig. 3) will add either "DX" or "test" to the call and will repeat the callsign three times. The memory of the modified sender is doubled by the addition of a second 74150, a 7476, and an AND gate to create a 32-line-to-1-line multiplexer. This allows the callsign to be repeated three times, although it is programmed only once in the diode matrix.

A double-pole, three-way switch selects the message

to be sent. As it is programmed in Fig. 3, the enhanced CQ Sender will send "CQ" five times, "DE," and then "VU2ARC" three times if the switch is in position 1. In position 2, the message will be "CQ CQ DX CQ DX" with the same sign-off, and in position 3 the sender will emit "CQ CQ TEST CQ TEST," again adding the same ending. In all three modes, it will complete the transmission with $\overline{\text{AR}}$ K.

(In the prototype, the word QRZ was also included as the fourth mode. Later on, it was found not very important and hence it is not shown in Fig. 3.)

Conclusion

With the RC values shown for the clock oscillator, the generated Morse speed can be varied anywhere between 8 and 15 wpm. After calling "CQ CQ DE VU2ARC $\overline{\text{AR}}$ K" once, a pause of about 8 seconds (at 8 wpm) occurs before it starts calling the CQ message once again. During this 8-second gap the transceiver will be in the receive mode to receive a possible reply. The relay output (normally-open contacts) can be connected in parallel with a straight key or to an automatic keyer.

The power supply for this unit was designed using the 7805 3-terminal 5-V voltage-regulator IC.

The programming can be altered simply by rearranging the diode positions in the diode matrix.

The circuit was assembled on a PCB and housed in a ready-made slim metal box and was demonstrated at our club meeting and also at the BEL ARC exhibition held recently in Bangalore. The design was much appreciated by the engineers and by many senior hams like VU2GSM, VU2GZ, and VU2IR. ■

Yasme and the Call of Abu Ail

It was just a speck in the Red Sea, but it created pileups as big as a mountain.

Lloyd Colvin W6KG
Iris Colvin W6QL
Yasme Foundation
Box 2025
Castro Valley CA 94546

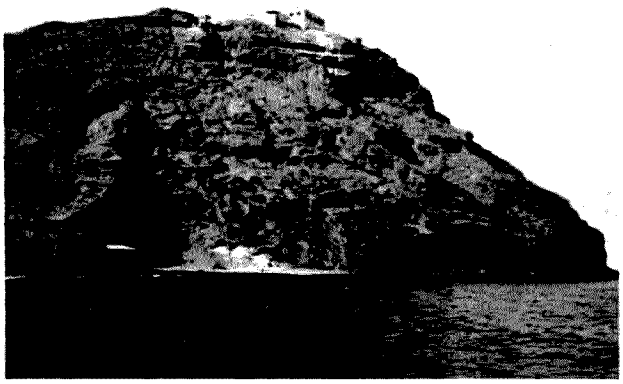
Yasme was the name of the boat on which a radio amateur named Danny Weil went forth in 1954 on a continuous worldwide trip devoted primarily to communication with other radio amateurs throughout the world. He was the first person in the world to make such an expedition. The Yasme Foundation was formed and, over the last two decades, nearly 100 Yasme DXpeditions to rare and semi-rare countries have been made with various operators participating.

This is the story of the December, 1982, Yasme DXpedition to Abu Ail, which is one of the rarest DX countries in the world. Preparations and correspondence pertaining to the trip were in the making for three years.

Abu Ail (with Jabal At Tair) is listed as a separate country by the ARRL. They are both islands with a lighthouse and people on them. Abu Ail is a 350-foot-high rock located in the Red Sea, on the major water route from the Indian Ocean through the Red Sea to the Suez Canal and on north to the Mediterranean. The island is well named (Arabian words meaning "Father Ail") because its lighthouse watches over and guides the many ships away from the rocks. None of them stop, and the lighthouse keeper stays there eight months at a time without leaving the lighthouse.

Abu Ail is an international island owned by no one nation. On a clear day, Ethiopia can be seen to the west and North Yeman to the east.

Permission was eventually obtained from the administrators of the islands, The Compagnie Maritime Auxiliare d'Outre-Mer in Djibouti—who are associated with Red Sea Lights of London—to visit the island and operate an amateur radio station there, thus making a DXpedition to Abu Ail possi-



Abu Ail and the cliff up which everything had to be carried.

Lloyd and Iris in the landing cove with a generator and some gasoline. The Fahnous *is in the background.*

ble. We have been going on Yasme DXpeditions for many years and did most of the planning of the trip up to this point. Additional help then was needed, and fortunately, two French amateurs, Christian Dumont FØECV and Jean Michel Gabouriaud F6GBQ, were recruited. (They are J28DP and J28DL in Djibouti.) They supplied generators and additional needed radio gear.

All four of us had to sign agreements that we and our heirs and assigns accepted full responsibility for any casualty or mishap that might occur. We agreed not to interfere with the functions of the lighthouse in any way whatsoever. We agreed to take with us anything that we needed in the way of food, water, generators, gasoline, and anything else that we might use.

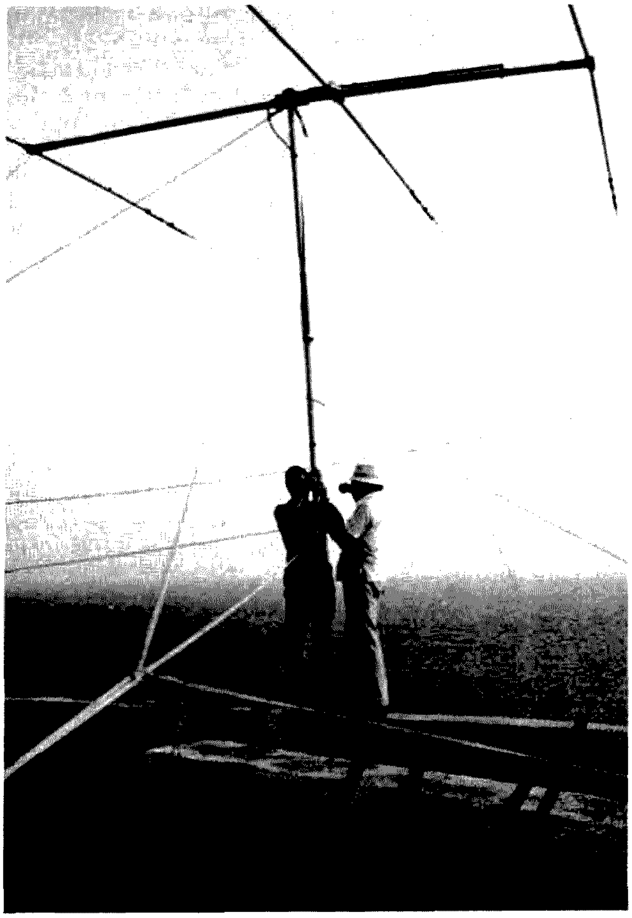
Arrangements were made for passage on the *Fahnous* (Arabian word meaning "lamp"), the supply ship that services the island monthly with food, water, and supplies. We agreed to pay for our passage and for the diversion of the ship from its regular route, putting us ashore on Abu Ail, continuing on to Jabal At Tair, and then returning 48 hours later to pick us up. We fully understood that the ship could not remain anchored near the island and that we must be ready and waiting to board quickly when the ship arrived.

We made a list of essentials, keeping in mind that time was limited and that everything must be carried up the steep cliff. The list included food and water for 48 hours, sleeping bags, gifts for the lighthouse keeper, and our radio equipment, consisting of two generators (one 1.5 kW and one 500 Watts), gasoline, antennas, coax, a Yaesu 707, a Kenwood 520, a Yaesu 902DM transceiver, and a Heathkit 230 amplifier.

The good ship *Fahnous* left Djibouti with the four of us and our equipment aboard at about 3:00 pm on December 4, 1982. The seas were extremely high during the night but were somewhat calmer when we arrived at Abu Ail at 8:00 am the following morning. All of our equipment and ourselves had to be transferred from the ship to a small dinghy. The seas were still rough, and the dinghy was bouncing up and down alongside the ship as much as 6 feet with each wave. Both the loading of the dinghy and the landing ashore were dangerous and tricky. It would have been very easy to have lost our equipment or suffered injury ourselves. Fortunately, the only mishap was to the dinghy, which hit a reef during the landing, causing some damage to its side. After landing, we started the ascent up the cliff with our equipment, giving priority to the actual radio gear. The wind blew continuously, making the trek up even more difficult.

By about 10 am, G5ACI/AA was on the air, using the vertical antenna, the Yaesu 707, and the small generator. A little after noon, both stations were in operation. The four of us took turns operating for sessions of approximately two hours each. At the same time, work was continued to bring the rest of the supplies up the hill and to put up doublets for 40 meters and the new 30-meter band.

We encountered a number of minor setbacks and delays. The limited space at the top of the rock made it impossible to locate the two stations far enough apart for both to operate on some frequencies simultaneously without interference. The guys for the TH3 had to be located over the edge of the cliff, which slowed the process of erecting the beam. We also ran into some difficulties in getting either the Yaesu 707 or the Kenwood 520 on CW operation.



Jean F6GBQ (left) and Lloyd W6KC erecting an antenna on Abu Ail. It is 350' almost straight down to water behind them.

The crew at G5ACI/AA. Left to right, Jean Michel Gabouriaud F6GBQ, Christian Serge Dumont FØECV, Lloyd Colvin W6KC, and Iris Colvin W6QL.

All obstacles were eventually overcome. We stayed on the air continuously, operating on 5 bands, both phone and CW. We made contact with over 4000 amateurs in 105 different countries.

At about 6:00 am on the morning of December 7th, we sighted the *Fahnous* approaching. We began dismantling the stations and pulling down the antennas. We bid farewell to the lighthouse keeper, who said that our visit was an exciting change from his usual routine. The descent was somewhat easier and faster than the ascent. The gasoline had been used up, and any extra food was left behind.

As we boarded the *Fahnous*, we felt tired and exhausted—but we also were very happy over the successful completion of Operation Abu Ail.

A few observations and recommendations to anyone going on a similar DXpedition are listed:

1. Be sure that you obtain proper authorization and licensing, in writing, well in advance.

2. If possible, set up the complete operation, including all equipment (generators, etc.), at your home base before going on the DXpedition. We did this and discovered and corrected a number of time-consuming problems on the test run. These included how to solve problems of guying antennas, what interference we could expect to find, and what frequencies to use when simultaneously operating several stations close to each other. We found that we could operate a station on SSB and a station on CW simultaneously on the 10-meter band—but this could not be done on the other bands.

3. If you are going to climb a steep mountain carrying 50 to 80 pounds, figure out in advance the easiest way to do this. We found that the best thing was to reduce weight. Do not carry one pound of anything that is not required!

4. Try to think of everything in advance. We had small lights to use for nighttime operation, but we forgot to carry shades for the days. We had to waste some DXpedition time fabricating makeshift shades.

5. Don't forget to bring earphones—we almost did. With the noise from generators and two stations operating at once, the use of headphones was essential.

6. Remember to bring a soldering iron. Something will come up when it will be needed. We used ours on two occasions.

7. Figure out in advance how you are going to keep your logs. We were so anxious to get on the air that we got our log-keeping of the two stations a little mixed up at the start.

8. If you are going by sea, bring seasick pills and use them. We had the pills OK, but one of our operators thought that he wouldn't need them. He did.

9. If you have any equipment requiring batteries, bring along extras. Both of our keyers and one flashlight required battery changes.

We were very lucky as to the ability of our operators. All four operators carried their fair share of both the physical work and the operating. All operators were trained, experienced DXers, and the handling of the pileups was no major problem.

The Yasme Foundation and everyone connected with it wish to thank the DX operators of the world for the general courtesy they showed in standing by until they could work the rare country of Abu Ail. ■

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

MAPLE RIDGE BC CAN
JUL 2-3

The Maple Ridge ARC will hold its Hamfest '83 on July 2-3, 1983, at the Maple Ridge Fairgrounds, 30 miles east of Vancouver on Highway #7. The registration fee for hams is $5.00 and for non-hams over 12, $2.00. Features will include a swap and shop, bunny hunts, ladies' and children's programs, and displays. Food and lots of camper space (some with hydro) will be available. Talk-in on 146.20/.80 and 146.34/.94. For registration information (20% off for pre-registration), contact Bob Haughton VE7BZH, Box 292, Maple Ridge BC V2X 7G2, Canada.

SHELLSVILLE PA
JUL 4

The Harrisburg Radio Amateur Club will sponsor the annual Firecracker Hamfest on Monday, July 4, 1983, at the Shellsville VFW picnic grounds, Exit #27 (follow signs 2 miles to Shellsville), I-81, north of Harrisburg. Admission is $3.00, XYLs and children will be admitted free, and there will be no charge for tailgating. There will be plenty of parking, shade trees, tables, and a pavilion. Talk-in on .16/.76 or .52/.52 simplex. For additional details and table reservations, contact KA3HZW, 131 Livingston Street, Swatara PA 17113, or phone (717)-939-4957.

SPOKANE WA
JUL 8-10

The 5-state ARRL Northwestern Division Convention will be held on July 8-10, 1983, at the Spokane Convention Center, Spokane WA. The Spokane Swapfest (normally in April) will be combined this year with the convention as will be the flea market. Registration is $5.00 and swap tables are $10.00. Events will include displays by manufacturers and dealers, seminars on antennas, computers, VHF/EME, weather, traffic handling, and repeater operation. There will be ARRL and advisory committee forums. Ladies' programs will include a luncheon and style show. The Saturday-night banquet will feature Roy Neal, NBC news correspondent, and the Royal Order of the Wouff Hong ceremony will follow at midnight ($1 admission). The DX breakfast and church services will be on Sunday morning. Close-in RV parking is available. For additional information, write Northwest '83, PO Box 3933, Spokane WA 99220.

FARIBAULT MN
JUL 9

The Faribault Amateur Radio Club will hold its 2nd annual swapfest on Saturday, July 9, 1983, from 9:00 am to 3:00 pm, at the Rice County Fairgrounds on the north edge of Faribault MN. General admission is $1.50, admission and selling space is $3.00 (indoor or outdoor), and tables (7-foot and by pre-registration only) are $3.00 each. Lunch and free parking will be available. There will be amateur radio and computer gear as well as electronic equipment displayed. Talk-in on 146.19/.79. For more information, contact Donald Klier, 1118 NW 8th Street, Faribault MN 55021.

OAK CREEK WI
JUL 9

The South Milwaukee Amateur Radio Club will hold its annual swapfest on Saturday, July 9, 1983, from 7:00 am to approximately 5:00 pm, at the American Legion Post #434, 9327 South Shepard Avenue, Oak Creek WI. Admission is $3.00 per person and includes a "Happy Hour" with free beverages. Parking, a public picnic area, hot and cold sandwiches, and liquid refreshments will be available on the grounds. There will be free overnight camping. Talk-in on 146.94. For more details, including a local map, write South Milwaukee Amateur Radio Club, Inc., PO Box 102, South Milwaukee WI 53172-0102.

STATE COLLEGE PA
JUL 9

The Nittany Amateur Radio Club will hold a hamfest and computer fair on Saturday, July 9, 1983, beginning at 8:00 am, at the Pleasant Gap Firemen's Park, Route 144, Pleasant Gap PA (just off Route 26, east of State College). Tickets are $3.00; tailgating spaces are $5.00. Talk-in on 146.16/.76 and 146.25/.85. For further information, write Dave Buckwalter KC3CL, 1635 Circleville Road, State College PA 18801, or phone (814)-234-0759.

MILTON ONT CAN
JUL 9

The Burlington Amateur Radio Club, Inc., will host the ninth annual Ontario Hamfest on Saturday, July 9, 1983, at the Milton Fairgrounds. For more information, write Burlington Amateur Radio Club, Inc., PO Box 838, Burlington ONT L7R 3Y7, Canada.

CROSSVILLE TN
JUL 9-10

The Plateau Amateur Radio Club will hold the Crossville Hamfest on July 9-10, 1983, at the Cumberland County Community Complex, Highway 70 North, Crossville TN. Admission is $1.00 for adults. Exhibit and flea-market space will be available on a first-come basis. There will be a Dutch-treat dinner on Saturday night. Talk-in on 147.93/.33. For further information, contact the Plateau Amateur Radio Club, PO Box 2621, Crossville TN 38555.

ALEXANDER NY
JUL 10

The Genesee Radio Amateurs, Inc., will hold the ARRL-approved third annual Batavia Hamfest on Sunday, July 10, 1983, from 6:00 am to 5:00 pm, at the Alexander Firemen's Grounds, Rte. 98, Alexander NY (9 miles south of Batavia). Registration is $2.00 in advance and $3.00 at the gate. Features will include a large exhibit area, OM and YL programs, contests, a boat-anchor auction, and overnight camping. Food will be available. Talk-in on 8.52 or 4.71/5.31 (W2RCX). For more information or advance tickets (make checks payable to Batavia Hamfest), write c/o GRAM, PO Box 572, Batavia NY 14020.

INDIANAPOLIS IN
JUL 10

The Indiana State Amateur Radio Convention, in conjunction with the Indianapolis Hamfest and Computer Show, will be held on Sunday, July 10, 1983, at the Marion County Fairgrounds at the southeastern intersection of I-74 and I-485. Gate tickets are $4.00 and entitle you to all activities. There will be inside and outside flea markets, a separate computer show and flea market, a commercial vendor's display area, technical forums, club activities, ladies' activities, and professional food services. There will be setups after 12:00 noon on Saturday, July 9th. Security will be provided Saturday night and Sunday, and camper hookup facilities will be available on the grounds. For further information, contact Indianapolis Hamfest, Box 11086, Indianapolis IN 46201.

DOWNERS GROVE IL
JUL 10

The DuPage Amateur Radio Club Hamfest/Computerfest will be held on Sunday, July 10, 1983, from 9:00 am to 4:00 pm, at the American Legion Post grounds, Downers Grove IL. Tickets are $2.00 and will be available only at the gate. There will be food, drinks, and plenty of parking space, as well as a large outdoor flea market. Talk-in on 144.89/145.49. For more information, send an SASE to W9DUP, PO Box 71, Clarendon Hills IL 60514, or call (312)-971-1156.

MONTANA-ALBERTA CAN
JUL 15-17

The 49th Glacier-Waterton International Hamfest will be held on July 15-17, 1983, at Waterton Homestead Campground, just north of Waterton National Park entrance on Highway 6 (Alberta, Can.). There will be a bunny hunt, technical sessions, entertainment, and swap tables. For more information and pre-registration, write PO Box 148, Milk River, Alberta T0K 1M0, Can.

CARY NY
JUL 16

The Cary Amateur Radio Club will hold its eleventh annual Mid-Summer Swapfest on Saturday, July 16, 1983, from 9:00 am to 3:00 pm, at the Lion's Club Shelter (next to Cary Senior High School), Cary NC. There is no admission or commission charge. Featured will be an open auction at 1:00 pm. Talk-in on 146.28/.88, 147.75/.15, and 146.52 simplex.

SHEBOYGAN WI
JUL 16

The annual Sheboygan County Amateur Radio Club Lakeshore Swapfest and Brat Fry will be held on July 16, 1983, from 10:00 am to 4:00 pm, at the Wilson Town Hall, south of Sheboygan WI. Tables are free and camping is available at Terry Andre State Park. There will also be a public auction. For a flyer and other information, write PO Box 895, Sheboygan WI 53081, or phone (414) 457-3203.

AUGUSTA NJ
JUL 16

The Sussex County Amateur Radio Club will hold its fifth annual hamfest, SCARC '83, on Saturday, July 16, 1983, at the Sussex County Farm and Horse Show grounds, Plains Road, off US Highway 206, Augusta NJ, just north of Newton. General registration is $2.00. There will be acres of free parking and outdoor flea-market space. Pre-registration for sellers is $4.00 ($5.00 at the gate). There will be a huge building for indoor sellers and pre-registration is $5.00 ($6.00 at the gate). Talk-in on 147.90/.30 and 146.52. For more information or registration, write Lloyd Buchholtz WA2LHX, 10 Black Oak Drive, RD 1, Vernon NJ 07462.

MANCHESTER NH
JUL 16

The New Hampshire FM Association will hold an electronics flea market on Saturday, July 16, 1983, beginning at 9:00 am, at the Manchester Municipal Airport. General admission is $1.00 per person (sellers, $5.00). Sellers should tailgate or bring their own table. Commercial displays are welcome. Refreshments will be available. Talk-in on 146.52 FM. For pre-registration, write NHFMA, Inc., 30 Meadowglen Drive, Manchester NH 03103. For further information, contact Dick DesRosiers W1KGZ at (603)-668-8880 or Doug Aiken K1WPM, 30 Meadowglen Drive, Manchester NH 03103, at (603)-622-0831.

EUGENE OR
JUL 16-17

The 8th annual Lane County Ham Fair will be held on July 16-17, 1983, at the Oregon National Guard Armory, 2515 Centennial, Eugene OR. Registration is $4.00 and swap tables are $5.00 each (2 maximum). Doors will open at 8:00 am both Saturday and Sunday and there will be a potluck supper at 6:00 pm on Saturday. Features will include a 2-meter bunny hunt, computer demos, technical seminars, swap tables, bingo, a Kiddie Korner, and women's activities. An all-day snack bar and free parking for RVs (no hookups) will be available. Talk-in on .52/.52, 146.28/.88, and 147.86/.26. For tickets or swap tables, send a check payable to Lane County Ham Fair to Tom Temby WB7WPU, Treasurer, 3227 Crocker Road, Eugene OR 97404, or phone (503)-689-1761.

PALMYRA IL
JUL 16-17

The Quad-Co. Amateur Radio Club will sponsor the 26th annual Hamfest of the Breakfast Club on July 16-17, 1983, at Terry Park, 3/4 mile east of Palmyra IL. Pre-registration until July 7, 1983, is $1.50 (at the gate $2.00). Camping facilities will be open from Friday afternoon until Monday morning. There will be games, contests, golfing, fishing, gear swapping, and on Saturday night, dancing and movies. Bring your own basket lunch; sandwiches and soft drinks will be available on the grounds. Talk-in on 3973 kHz from noon Saturday until 11:00 am Sunday. For more information, write Hamfest, c/o Quad-Co. ARC, 602-D East Walnut, Chatham IL 62629.

LAPORTE IN
JUL 17

The combined LaPorte-Michigan City Amateur Radio Clubs will hold their Summer Hamfest on Sunday, July 17, 1983, from 8:00 am to 2:00 pm, at the LaPorte County Fairgrounds, State Road 2, west of LaPorte IN. The donation is $3.00 at the gate. Good food, cold drinks, and paved outdoor parking will be available. For reservations for indoor tables (40¢/foot), write PO Box 30, LaPorte IN 46350.

EDGEWATER PARK NJ
JUL 17

The 5th annual West Jersey Radio Amateurs Hamfest will be held on Sunday, July 17, 1983, 9:00 am to 3:00 pm, rain or shine, at the Super 130 Drive-In Theatre, Route 130, Edgewater Park NJ (2 miles south of Burlington, 8 miles north of Palmyra). Registration is $3.00 and tailgating is $3.00 (sellers must bring their own tables). Early setup for vendors only is at 7:00 am. Talk-in on 147.75/.15, 144.87/.47, and 146.52. For further information or to order tickets, send an SASE to Mary Lou Shontz N2CLX, 107 Spruce Lane, Route 16, Mount Holly NJ 08060, or phone (609)-267-3063.

CANTON OH
JUL 17

The Tusco ARC (W8ZX) and the Canton ARC (W8AL) will present the 9th annual Hall of Fame Hamfest on Sunday, July 17, 1983, at the Nimishillen Grange, 6461 Easton Street, Louisville OH. Tickets are $2.50 in advance, $3.00 at the gate, and children under 16 will be admitted free. Flea-market parking is $2.00 and tables are available on a reserved basis at $3.50 each. For additional information, write Art Holmes WA2TIF, 2 Straub Drive, Pleasant Valley NY 12569, (914)-635-2614, or Walt Sutkowski K2DPL, W. Redoubt Road, Fishkill NY 12524, (914)-897-5158.

GLENWOOD SPRINGS CO
JUL 23

The Ski Country Amateur Radio Club will hold its second annual swapfest on July 23, 1983, at Colorado Mountain College, 1402 Blake Avenue, Glenwood Springs CO. There is no admission charge. Tables are $5.00 each. Talk-in .07/.67. For further information, contact Frank WA0BBI, Box 280, El Jebel CO 81628.

WELLINGTON OH
JUL 23

The Northern Ohio Amateur Radio Society will hold NOARSFEST on Saturday, July 23, 1983, from 8:00 am to 5:00 pm, at the Lorain County Fairgrounds, Route 18, 1/2 mile west of Route 58, Wellington OH. Donations are $2.50 in advance and $3.50 at the gate. Children under 12 will be admitted free. Parking for the flea market is $1.00 per car space. Flea-market setup is from 6:00 am to 8:00 am. Plenty of free parking will be available in a large general parking area. Indoor exhibit spaces with an 8-foot table are $8.00 each. Send check for advance registration to Don Winner WD8RZG, 8927 Torrance Avenue, Brooklyn OH 44144, or phone (216)-749-6594. There will be refreshments and 807s will be furnished by NOARS. Campers may park overnight Friday at no charge but no hookups will be available. Talk-in on 146.52/.52 (K8KRG) and 144.55/145.15. For admission tickets, write NOARSFEST, PO Box 354, Lorain OH 44052.

SEATTLE WA
JUL 29-31

The Western Washington DX Club (W7FR) will host the 31st annual Northwest DX Convention on Friday, Saturday, and Sunday, July 29-31, 1983, at the Double Tree Plaza Hotel, located near the South Center Shopping Mall and the Seattle-Tacoma Airport. There will be a Saturday night banquet and a Sunday morning breakfast, as well as speakers, slides, symposia, and awards. Talk-in on 146.40/147.00 (W7FR). For registration, contact Ruth Bennett WA7RVA, 6729 Beach Drive SW, Seattle WA 98116, or phone (206)-932-1335. For further information, contact WA7RVA or Roy Foote N7AIF, Chairman, 3029 48th Avenue SW, Seattle WA 98116, or phone (206)-935-8041.

OKLAHOMA CITY OK
JUL 29-31

The Central Oklahoma Radio Amateurs will hold the ARRL State Convention at Ham Holiday '83 on July 29-31, 1983, at the Myriad Convention Center, Oklahoma City OK. Pre-registration is $6.00 ($7.00 at the door). Children age 12 and under will be admitted free with a parent. Every pre-registrant may buy one flea-market table for $1.00. In addition to the noncommercial flea market, there will be displays, forums, programs, special group meetings, and a buffet and dance on Saturday night. Ample parking will be available and hotel accommodations with special Ham Holiday rates are nearby. For further information or pre-registration forms, write CORA, PO Box 14268, Oklahoma City OK 73113.

CUMBERLAND ME
JUL 30

The Blackstrap Repeater Association will hold the second annual Greater New England Hamfest on Saturday, July 30, 1983, from 8:00 am to 5:00 pm, at Cumberland Fairgrounds, Cumberland ME. Tickets are $1.00 in advance and $2.00 at the gate. There will be forums, exhibits, meetings, speakers, dealers, and a giant flea market. Food and free camping will be available. Talk-in on 147.69/.09, 146.52, 3.940, and 146.13/.73. For more information, call Ed Williams KA1FZD at (207)-846-3509.

ISHPEMING MI
JUL 30

The Hiawatha Amateur Radio Association of Marquette County, in celebration of its 50th anniversary, will sponsor the 35th annual Upper Peninsula Hamfest on July 30, 1983, from 9:00 am to 5:00 pm, at the Michigan National Guard Armory in Ishpeming. Registration is $1.00 and tables will be available for $3.00 each. Features will include a computer demonstration and net meetings. Talk-in on 146.16/.76. For more information, contact George Lehtinen W8IOC, 100 N. Daisy, R2, Ishpeming MI 49849, or phone (906)-485-5038.

ASHEVILLE NC
JUL 30-31

The Western Carolina Amateur Radio Society will sponsor the WCARS Hamfest and Computer Fair of 1983 on July 30-31,

I need a source for a 1N23B diode used in a General Radio Slotted Line 874.

Rudolf E. Six KA8OBL
30725 Tennessee
Roseville MI 48066

1983, beginning at 9:00 am, at the Buncombe County Fireman's Training Center, Asheville NC. Features will include an ARRL booth and seminar by Bob Grove WA4PYQ, McElroy Memorial CW competition, a flea market, bingo, RV parking and free camping (no hookups), and computer hardware and software. Talk-in on .31/.91, .61/.76, and .52 simplex. For ticket information, write Garland Lance NC4N, 854 Sandhill Road, Asheville NC 28806.

OLIVER BC CAN
JUL 30-31

The Okanagan International Hamfest will be held on July 30-31, 1983, at Oliver Centennial Park, Oliver BC. Registration will be at 9:00 am (PDT) on Saturday, July 30th and the activities will be from 1:00 pm on Saturday through 2:30 pm on Sunday. YLs may bring crafts, hobbies, and flea-market items for sale or display. There will be a potluck luncheon on Sunday, as well as entertainment and bunny hunts. Talk-in on the .34/.94 repeater or .76/.76. For further information (no advance reservations), write John Juul-Andersen VE7DTX, 8802 Lakeview Drive, Vernon BC V1B 1W3 or Lota Harvey VE7DKL, 584 Heather Road, Penticton BC V2A 1W8.

ALEXANDRIA LA
JUL 30-31

The Central Louisiana Amateur Radio Club will hold a hamfest on Saturday and Sunday, July 30-31, 1983, at the Bolton Avenue Community Center, Alexandria LA. Swap tables will be available.

BELVIDERE IL
JUL 31

The Belvidere Amateur Radio Association will hold its annual hamfest on July 31, 1983, at the Boone County Fairgrounds, Route 76, Belvidere IL. Admission is $2.00 in advance and $2.50 at the door. Tables may be reserved for $2.00. There will be plenty of free flea-market spaces and, if it rains, there will be inside space available. There will be camping on Saturday night. Talk-in on 146.52. For more information, contact Bob Anderson K9DCG, 910 Locust Street, Belvidere IL 61008.

CENTREVILLE MI
JUL 31

The Amateur Radio Public Service Association of Saint Joseph County MI will hold its 5th annual swap and shop on Sunday, July 31, 1983, at the Saint Joseph County Fairgrounds, Centreville MI. Doors will open at 8:00 am. Tickets are $2.00 in advance and $3.00 at the gate. Indoor tables are $3.00; trunk sales are free. Camping will be available on Saturday night only for $6.00. Talk-in on .52. For more information, contact Warren Harder N8EOX, 14820 Broadway Road, Three Rivers MI 49093.

JACKSON WY
AUG 5-7

The 1983 ARRL Rocky Mountain Division Convention, in conjunction with the 51st WIMU Hamfest, will be held on August 5-7, 1983, at the Virginian Motel, Jackson WY. Talk-in on 146.22/.82 and .3923 kHz. For reservations, call the Virginian at (307)-733-2792. For more information, phone R. L. "Pete" Stull WB7AMP at (307)-382-9032 or Dave Gregory N7COA at (307)-875-5324.

MOBERLY MO
AUG 7

The NEMO ARC of Kirksville MO and the Tri-County ARC of Moberly MO will hold the 5th annual North Missouri Hamfest on Sunday, August 7, 1983, at the Moberly Municipal Auditorium, Moberly MO. The auditorium has 12,000 square feet of air-conditioned space for the inside flea market and there will be a limited number of tables available free. Tickets are $1.50 in advance or $2.50 at the door. Doors will open for the flea market and distributors beginning at 8:00 am and for the hamfest, from 9:00 am until 3:00 pm. There will be forums, films, sandwiches, and drinks, as well as donuts and coffee for the early birds. Talk-in on 147.69/.09. For more information and/or tickets, contact Sam Fischer KA8ILO, PO Box 341, Moberly MO 85270.

ANGOLA IN
AUG 7

The Steuben County Radio Amateurs will hold their 25th annual FM Picnic and Hamfest on Sunday, August 7, 1983, at Crooked Lake, Angola IN. Admission is $2.50. Features will include picnic-style BBQ chicken, inside tables for exhibitors and vendors, a large electronics flea market, and overnight camping (fee charged by county park). Talk-in on 146.52 and 147.81/.21.

AUSTIN TX
AUG 12-14

The Austin Amateur Radio Club and the Austin Repeater Organization will sponsor Austin Summerfest '83 on August 12-14, 1983, at the Austin Marriott Hotel, Interstate 35 at Highway 290. Admission is $5.00 in advance and $6.00 at the door. Swapfest tables are available on a first-come, first-served basis, but each seller may also reserve one table in advance for $1.00. Summerfest '83 will combine the Texas VHF-FM Society Convention with forums, meetings, an indoor swapfest, dealer exhibits, and many outside activities for the family at Austin's annual Aqua Festival. Talk-in on 146.34/.94. For more information, write Austin Summerfest '83, PO Box 13473, Austin TX 78711.

DUNKIRK NY
AUG 13

The Lake Erie International Hamfest Association will hold its fifth annual Lake Erie International Hamfest on Saturday, August 13, 1983, beginning at 8:00 am, at the Chautauqua County Fairgrounds, Dunkirk NY. Admission is $2.50 in advance and $3.00 at the gate. Each flea-market space is $1.00 plus admission. There will be indoor dealer exhibits as well as a large flea market. Talk-in on 146.25/.85 and 146.52. For more information, write Lake Erie International Hamfest, PO Box 455, Dunkirk NY 14048.

POMONA CA
AUG 13

The Tri-County Amateur Radio Association will sponsor the TCARA 13th Annual Hamfest and Picnic on Saturday, August 13, 1983, from 8:00 am to 2:00 pm, at the Los Angeles County Fairgrounds in Pomona CA. Tables will be available for ham/computer exhibits and displays. There will be sandwiches and soft drinks available. For more information, contact Tony Skvarek W6ELZ, 1514 W. Mission #14, Pomona CA 91766.

BURLINGTON VT
AUG 13-14

The Burlington Amateur Radio Club will hold its annual International Hamfest and Flea Market on August 13-14, 1983, at the Old Lantern Campgrounds, Charlotte VT. For both days, tickets are $4.00, outdoor flea-market spaces are $2.00, and indoor spaces are $5.00. Food and drink will be available. Talk-in on .34/.94, .01/.61, and .52 simplex. For further information, contact Frank W1CTM, Burlington Amateur Radio Club, PO Box 312, Burlington VT 05402.

WILLOW SPRINGS IL
AUG 14

The Hamfesters Radio Club, Inc., will hold their 49th annual hamfest and picnic on Sunday, August 14, 1983, at Santa Fe Park, 91st and Wolf Road, Willow Springs IL (southwest of Chicago). Tickets are $2.00 in advance and $3.00 at the gate. Featured will be the famous swappers' row. There will be exhibits for OMs and XYLs. For advance tickets, send a check or money order and an SASE to Hamfesters, PO Box 42792, Chicago IL 60642.

FCC

10-YEAR LICENSES

Hoping to save both time and money, the FCC has proposed that the length of amateur licenses be extended to 10 years, with a 2-year grace period for renewing expired licenses. In its comments, the Commission noted that license renewals, which were up to 36,000 in 1982, would be reduced to about 12,000 per year. In addition, the number of licenses which are allowed to lapse inadvertently would decrease, according to the FCC.

Here is the Commission's proposed Part 97 amendment, as it appeared in the *Federal Register*.

PART 97—[AMENDED]

Appendix

It is propsed to amend Part 97 of the Commission Rules, 47 CFR Part 97, as follows:

1. In § 97.13, paragraph (d) would be revised to read as follows:

§ 97.13 Renewal or modification of operator license.

* * * * *

(d) If a license is allowed to expire, application for renewal may be made during a period of grace of two years after the expiration date. During this two year period of grace, an expired license is not valid. A license renewed during the grace period will be dated currently and will not be backdated to the date of its expiration. Application for renewal shall be submitted on FCC Form 610 and shall be accompanied by the applicant's expired license.

(2) In Section 97.47, paragraph (b) would be revised to read as follows:

§ 97.47 Renewal and/or modification of amateur station license.

* * * * *

(b) If a license is allowed to expire, application for renewal may be made during a period of grace of two years after the expiration date. During this two year period of grace, an expired license is not valid. A license renewal during the grace period will be dated currently and will not be backdated to the date of expiration. An application for an individual station license shall be submitted on FCC Form 610. An application for an amateur club or military recreation station license shall be submitted on FCC Form 610-B. In every case the application shall be accompanied by the applicant's expired license or a photocopy therof.

(3) In Section 97.59, paragraphs (a) and (b) would be revised to read as follows:

§ 97.59 License term.

(a) Amateur operator licenses are normally valid for a period of ten years from the date of issuance of a new, modified or renewed license.

(b) Amateur station licenses are normally valid for a period of ten years from the date of issuance of a new, modified or renewed license. All amateur station licenses, regardless of when issued, will expire on the same date as the licensee's amateur operator license.

20M PHONE EXPANSION

After a three-year battle, the 20-meter phone-band expansion went into effect on May 22. The new frequency allocation gave General-class operators use of the frequencies between 14.225 MHz and 14.275 MHz. Advanced-class licensees have phone privileges between 14.175 and 14.225 MHz, and Extra-class ticket holders are allowed to operate phone from 14.150 to 14.175 MHz. The Commission's amendments to Part 97, as published in the *Federal Register*, are shown below.

PART 97—[AMENDED]

Part 97 of the Commission's Rules and Regulations, 47 CFR Part 97, is amended as follows:

1. In § 97.7, paragraph (a) is revised to read as follows:

§ 97.7 Privileges of operator licensee.

(a) Amateur Extra and Advanced Class. All authorized amateur privileges including exclusive frequency operating authority in accordance with the following table:

Frequencies	Class of license authorized
3500-3525 kHz	Amateur extra only.
3775-3800 kHz	Do.
7000-7025 kHz	Do.
14,000-14,025 kHz	Do.
14,150-14,175 kHz	Do.
21,000-21,025 kHz	Do.
21,250-21,270 kHz	Do.
3800-3890 kHz	Amateur extra and advanced.
7150-7225 kHz	Do.
14,175-14,225 kHz	Do.
21,270-21,350 kHz	Do.

* * * * *

§ 97.81 [Amended]

2. In § 97.81, in the table in paragraph (a), the row beginning with "14000-14200 (kHz)" is revised by beginning the row with "14000-14150 (kHz)" so that the entire row reads as follows:

14000-14150 .... F1

3. Also in § 97.81, in the table in paragraph (a), the row beginning with "14200-14350 (kHz)" is revised by beginning the row with "14150-14350 (kHz)" so that the entire row reads aa follows:

14150-14350 ________ A3, A4, A5, F3, F4, F5

E.T. FEEDBACK

My wife and I both enjoyed the article on "How E.T. Really Called Home." When we saw the movie and Elliott and E.T. set the communicator up, I said, "That looks like something a ham would build." Looks like I *was right!*

Stephen Wimmer WB0GGT
Raymond NE

THE ELITE MODE

The solution to the question of code or no code can be answered to the satisfaction of everyone. The proponents of code offer the ability to "get through with CW when voice is unintelligible," narrower *bandwidth, etc., as proof that CW is the* ultimate skill that everyone should have as their goal. The thing I don't understand is, if CW is so damned good, why isn't it reserved for the select group that can master it and that have the technical expertise necessary to pass the Advanced- and Extra-class tests?

Instead of reserving CW for those who are most deserving of its fantastic benefits, the CW proponents prefer restricting those least deserving of its benefits to using only CW.

It just plain seems backwards. What needs to be done is to restrict Novices and Techs to voice until they've earned the right to use the far superior method of communicating, namely CW. Under this system, the highest class licensees would be able to use the best possible means of communicating, up to and including CW, while the lower class licensees would be restricted to the less efficient methods, i.e., voice.

What could be simpler or fairer? People who can't master or have no interest in mastering CW wouldn't be saddled with it *while those who do enjoy it would have the* added satisfaction of having the "best," to some extent, reserved for them.

James Delton N7ECC
Tempe AZ

Troublemaker.—Wayne.

FOR VIETNAM VETS

An open letter to all veterans of the US military during the Vietnam era who are now amateur radio operators:

We are trying to form a net of radio operators for each state to participate in communication with each other and with the nonprofit organization, Vietnam Veterans of America. Our objective is to reach all the vets of that era and band together for the purpose of brotherhood, benefits, and discussion of the effects of chemical warfare on us.

We will be publishing a newsletter and participating in the First Annual Convention for the Vets of the Era, in Washington, DC, on November 7-10. If you are interested in participating, contact Mike Kelly, 2101 Crescent Avenue, Eau Claire WI 54701, (715)-834-1738, or Larry Mittman N9AUG, Box 158, Rt. 5, Eau Claire WI 54701, (715)-874-6473.

Vietnam Veterans of America is a non-*profit combat veterans organization certi*fied by the Congress of the United States.

Mike Kelly
Eau Claire WI

GUEST SPEAKER

You mentioned in the December, 1982, issue the woeful lack of good speakers at hamfests. I would like to offer my services to any interested hamfest/radio club. I am the Kentucky state coordinator for the Radio Amateur Satellite Corporation (AMSAT), and I have been active in amateur satellite communication for five years. I have a set of slides and I have a simple non-technical program which will explain the past, present, and future of amateur space activity. I also served a stint as technical editor of *73*, and I can talk about what it's like to work for the best magazine in amateur radio. If your club has any aspiring authors, I can tell you what makes an article worth buying.

I will travel anywhere there is a hamfest or club meeting. The only fee that I require is my travel expenses. I have access to a private plane so I can go anywhere in the eastern USA.

Charles E. Martin AB4Y
Box 3370
Bowling Green KY 42101

BEACON UPDATE

Here is an update on ten-meter beacons for the readers of *73*. The KA1YE/B beacon *in southeastern Connecticut has been* joined by at least two others in the US. They are: WA1IOB/B in the Boston area on 28.208 MHz, and W3VD/B in Laurel, Maryland, on 28.295 MHz. I haven't heard the IOB beacon here, but W3VD/B can be heard on backscatter.

Reception of the KA1YE and WA1IOB beacons has been reported in Great Britain in *Practical Wireless* magazine. In the May, 1983, issue there is a listing of 19 beacons worldwide with a graph displaying dates of reception in the UK. The beacons are from all continents, with VE2TEN being the only other North American beacon listed.

A listing of active beacons is being maintained by Willi HB9AVE. I have sent him the information on my beacon, and he would appreciate information from other individuals and groups operating ten-meter beacons. There is a limited amount of space allocated for unattended operation of beacons on ten meters here in the US, so some prior listening and coordination is highly recommended before putting on a *beacon. This also holds for other bands.*

I am willing to act as a clearinghouse for US beacons, keeping a file on activities and other information. If anyone is planning to put a beacon on ten, or knows of any other beacons active or planned, I would appreciate hearing about them. Please drop me a line. Thanks very much.

W. Keith Hibbert KA1YE

A DREAM COME TRUE

On March 30, 1983, I walked into the FCC field office at Syracuse, New York, with a Technician-class license. I walked out with a General-class interim permit. That permit is a dream come true and it has been a 27-year wait.

The reasons why I passed the code test were that I studied the code each day and I used your "Back Breaker" (CT7313) code tape. After two previous failures of the code test, I decided to use your tape. So, thank you very much for the help. Please keep up the good work at *73*.

(Re no-code licensing: I'm dead against it.)

Ben Alabastro WA2PXR
Frankfort NY

Right on there, Ben. If you and I have to suffer, then why shouldn't everyone? And think of the money I'll lose if they pass a no-code license and my code tapes stop selling. That 13-per tape is a rough one. . . I made that almost impossible so that you'd have clear sailing once you mastered it.—Wayne.

MODEM MAGIC

You're always interested in new technical ideas, so here's one you can think about. How about using our standard computer modems over the air and standardizing on these shift frequencies for computer-to-computer communications?

A modem for the VIC-20 is about $100, while commercial RTTY modems start at $150. The phone-line (Bell 103) modems use frequencies of 1070/1270 and 2025/2225 Hz. We could standardize on the lower two frequencies, since they're easily passed by receivers and transmitters, and the 200-Hz shift is within the FCC limits.

The only difficulty is that we'd have to shift the modems from the ORIGINATE position during transmit to the ANSWER position during receive. A relay could do this, and it seems to be a small price to pay to get one modem to serve double duty.

Anyone interested in giving it a try?

Jonathan A. Titus KA4QVK
Blacksburg VA

Hey! Do it and write an article! And you people in Nashua NH, you write one, too!—Wayne.

MULTI-BAND SLOPERS
160, 80, and 40 meters

Outstanding DX performance of slopers is well known. Now you can enjoy 2 or 3 band BIG-SIGNAL reports! Automatic bandswitching • Very low SWR • Coax feed • 2kw power • Compact • Ground or tower feed • Hang from any support 25 ft. high or higher • Easy to install • Very low profile • Complete instructions • Immediate shipment • Check ok

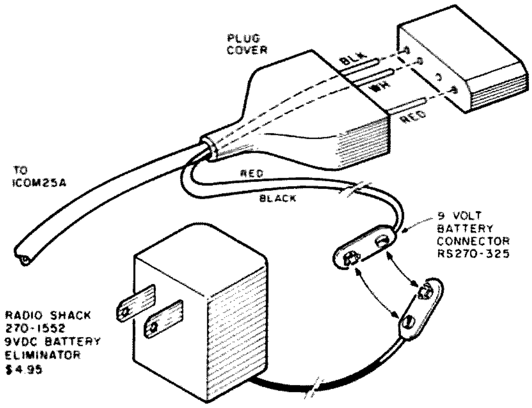
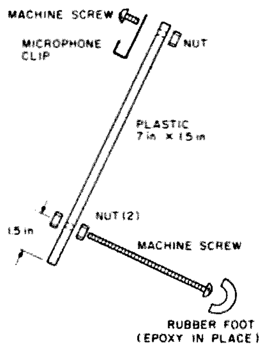
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



MEMORY BACKUP FOR THE ICOM 25A: To retain the memory in the Icom 25A when the power is disconnected, slip back the cover of the power plug and wire a 9-V battery connector to the white (positive) and black (negative) leads. When removing the rig from its power source, snap on a 9-V transistor battery or connect it to a plug-in transformer—Paul Van Bolhuis W4ZBD, Bradenton FL.



SIDE VIEW

MICROPHONE HOLDER FOR MOBILE RIGS: Keep your operating area organized and neat when you are using a mobile rig as a base station. This holder will keep your microphone within easy reach yet out of the way, and the parts for it can be found in almost any junk box.—Thomas Hart AD1B, Westwood MA.

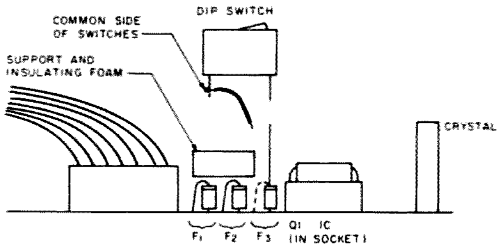


Fig. 1. Side view

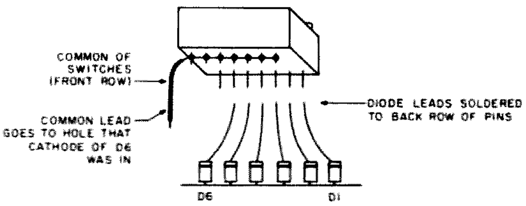

Fig. 2. End view (parts omitted for clarity).

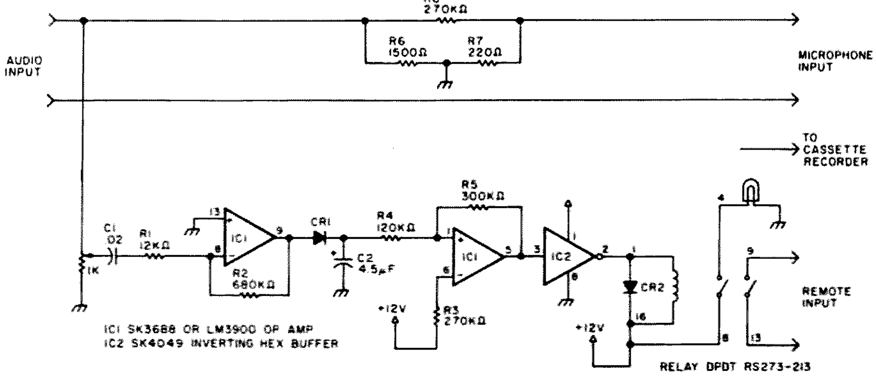
SWITCH-SELECTABLE TONES FOR THE KENWOOD 7950/7930: The TU-79 tone unit for the Kenwood 7950/7930 provides for the selection of 3 preprogrammed tones from the keyboard. With the following modification, the third frequency may be programmed by setting a DIP switch rather than cutting or soldering diodes. First, program the tones for F1 and F2 and verify that they work. Unsolder the cathode leads of the diodes in row F3 and position them as shown in the diagrams. Then mount a piece of stiff insulating foam over the diodes in rows F1 and F2, securing it firmly in place. Orient a 6- or 7-position rocker-type DIP switch so that the pole numbers align with the diode numbers 1 through 6 on the PC board. Solder a common wire to all of the leads on one side of the switch as shown in Fig. 1. Solder diode leads 1 through 6 to the corresponding switch pins; solder the common wire to the hole which previously held the cathode wire from D6. Be careful when making the modification; on my instruction sheet, diodes D1 through D6 were shown in reverse order, but the markings on the PC board were correct.—Clint Williams KB8SY, Portage MI.

EASY COAX CONNECTIONS: Much time and effort can be saved when working with large-diameter coax such as RG-8/U by using a small, inexpensive tubing cutter to help with the stripping. These cutters can be obtained at most local hardware stores and are listed as ⅛- to ⅝-inch copper tubing cutters. Use the cutter to score the jacket of the coax and then simply peel off the jacket. This eliminates the nicked and damaged braid that often accompanies coax work. When the jacket has been removed and the braid exposed, use a soldering gun or high-wattage iron to quickly tin the braid in place. Now, use the tubing cutter to cut through the rigid braid just as if it were tubing. Cut deep enough to remove the braid but do not damage the inner insulation. The inner insulation can also be cut with the tubing cutter but I find it easier just to use a knife at this point. The resulting job is very neat, virtually guarantees no nicks, and makes it very easy to attach a PL-259 connector since the braid is already tinned.—Craig Crichton K7UKW, The Dalles OR.



AUTOMATIC TAPE RECORDING: Don't miss the action while you're away from the rig. This circuit turns on a tape recorder whenever the receiver's squelch is broken. After signal loss, the recorder will shut off following a slight delay.—Gary Anderson KE7H, Nampa ID.

VENEZUELAN WORLDWIDE CONTEST

SSB—Starts: 0000 GMT July 2
Ends: 2400 GMT July 3

CW—Starts: 0000 GMT July 30
Ends 2400 GMT July 31

The Radio Club of Venezuela invites all amateurs to paticipate in the 21st year of the Venezuelan Independence Worldwide Contest. Use all bands, 80 through 10 meters. Operating classes include: single operator, one band (for each band); single operator, multi-band; multi-operator, multi-band, one transmitter; and multi-operator, multi-band, multi-transmitter.

EXCHANGE:

RS(T) plus a three-digit QSO number starting with 001.

SCORING:

Contacts between stations of different countries count two points. Contacts with stations within one's own country do not count but are valid as multipliers for each band. Count one multiplier for each Venezuelan and USA call area and each country (including own) worked on each band. Use the ARRL DXCC country list. Final score is the total QSO points times the total multiplier points.

AWARDS:

For stations outside Venezuela there will be a plaque presented to the highest scorer in each class. Medals go to the highest scorer in each continent and among the Bolivarian countries (Bolivia, Columbia, Ecuador, Panama, and Peru) in the single-operator, multi-band class. Certificates to all stations in the Americas working 15 YV stations and 10 different countries, all European and African stations working 10 YV stations and 10 different countries, and all Asia and Oceania stations working 5 YV stations and 10 different countries.

ENTRIES:

Logs must show date and time in GMT, station worked, reports exchanged and respective numerical order, multipliers, and points. Use different sheets for each band worked. Include a separate summary sheet showing name(s) of operator(s), callsign, and address. Each participant must include $2.00 US or IRC equivalent with their logs. Entries must be postmarked no later than August 15 for SSB and September 15 for CW and should be addressed to: RCV, PO Box 2285, Caracas 1010-A, Venezuela.

INTERNATIONAL WORLDWIDE DX SSTV CONTEST

Starts: 0000 GMT July 15
Ends: 2400 GMT July 17

This is the third annual DX SSTV contest sponsored by *A5 Magazine*. It is a 48-hour SSTV video contest using 80 thourgh 10 meters within the recommended SSTV calling/operating frequencies listed below. To encourage allband contest usage and promotion, extra bonus points are granted on the 10-, 15-, 40-, and 80-meter band segments. Single- and multi-operator stations are recognized with crossband contacts not permitted. Individual contacts count only once per band with repetitive multiband contacts acceptable.

Barring any unforeseen changes from last year's rules, callsigns and video reports must be in "video" form. Mugshots of the station operator, family, or friends can count only once. Slower clock-rate speeds are encouraged in either 128/16.5- or 256/31-second time bases. Color work must contain a minimum of a 2-color overlay to qualify with standard RGB frame transmissions. Motion SSTV must have a minimum of 2 frames sent with automatic receive switching circuitry or manually operated switching by the receiving operator and 64 x 64 "quadrant" storage of no less than 4 separate pictures with replays.

SCORING:

Each SSTV two-way contact is worth 5 points within the same country, 10 points for DX out of country. Contact bonus points are available as follows: Mugshots—1 point, slow speed—2 points, quad frame—3 points, motion SSTV—4 points, high resolution—5 points, and color SSTV (RGB)—10 points. A band multiplier of 3 can be claimed for contacts on 40 and 80 meters, 2 for contacts on 6, 10, and 15 meters. Stations with over 25 DX countries worked add 25 points, over 50 DX countries add 50 points, over 100 countries add 100 points!

FREQUENCIES:

Advanced/Extra—3845, 7220, 14230, 21340, 28680, 50.150.

General—3990, 7290, 14340, 21440, 28680, 50.150.

AWARDS:

First-place winner receives a 3-year subscription (worth $60) to *A5 ATV Magazine* with front-cover picture plus a gold certificate. Second- and third-place winners receive one-year subscriptions and gold certificates. All entries regardless of score receive gold certificates suitable for framing. Results will be in the November issue of *A5 ATV Magazine*.

ENTRIES:

Submission of logs and totaled scores must be postmarked no later than August 1 and submitted to: Contest Manager, *A5 ATV Magazine*, PO Box H, Lowden IA 52255-0408. Logs will be returned as will any photos, etc. Some log sheets and DX country lists are available from WB0OCD.

BROTHERS AND SISTERS QSO PARTY

The Central Oregon Radio Amateurs (CORA) are sponsoring the contest that will run from 0600 PST Saturday, July 23, until 1200 PST Sunday, July 24. Operations will be from WN7ODD in Brothers, Oregon, and N7CSH in Sisters, Oregon. Phone frequencies will be 10 kHz up from the bottom portion of the General bands. CW will be 15 kHz up from the bottom portion of the Novice bands. QSL via CORA, PO Box 723, Bend OR 97709. Enclose a business-size SASE for return QSL cards.

THE ARC LITE

NEWSLETTER OF THE MONTH

To create a good club newsletter, you don't have to have fancy graphics, typeset text, or professional writers—just a desire to inform and entertain your readers and a willingness to work at it. *The Arc Lite*, newsletter of the Garland Amateur Radio Club in Garland, Texas, is a perfect example of what can be done with simple resources and a little elbow grease.

The Arc Lite is neither typeset nor printed, but the first impression you get is that it is very clean. Obvious care has been taken in its layout, making the most advantageous use of white space without creating an empty look. Each page is bordered with a black line, and stories of special note—such as a recent issue's news flash of the expanded 20-meter phone band—are boxed, giving the newsletter the ambience of a tabloid newspaper.

Each section has been painstakingly labeled with a handsome headline and when a story jumps from one page to another, you are told where it has been continued.

Oddly enough, *The Arc Lite*'s contents are not that variant from the offerings of most other newsletters. Minutes of the last meeting, club news, and information on the club's repeater and station are all standard fare. But there is a difference. The sentences are complete. Misspellings are rare. For newsletter editor Gary Engleman K5HGL, the world of grammar and syntax is obviously not uncharted territory.

In his editorial, "de: Editor," Gary notes that he is selling advertising to help support the new *Arc Lite* format which he created. Gary has obviously seen a need for improvement and engineered a way to make the new idea work.

If your club takes pride in its newsletter, *73* wants to see it. To enter in *73*'s contest, send a copy of the newsletter to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

CW COUNTY-HUNTER'S CONTEST

Starts: 0000 GMT July 30
Ends: 0200 GMT August 1

The CW County-Hunter's Net invites all amateurs to participate in this year's contest. All mobile and portable operation in less active counties is welcomed and encouraged. Stations may be worked once per band and again if the station has changed counties. Portable or mobile stations changing counties during the contest may repeat contacts for QSO points.

EXCHANGE:

QSO number; category (P for portable, M for mobile); RST; state, province, or country; and US county. Stations on county lines give and receive only one QSO number, but each county is valid for a multiplier.

FREQUENCIES:

3575, 7055, 14065, 21065, and 28065. It is strongly requested that only P- or M-category stations call CQ or QRZ on 40 meters below 7055 and on 20 meters below 14065, with all other stations spreading out above those frequencies.

SCORING:

QSOs with fixed stations are 1 point, OSOs with portable or mobile stations are 3 points. Multiply the number of QSO points times the number of US counties worked. Mobiles and portables calculate their score on the basis of total contacts within a state for the state certificate, and on all operation if they operated from more than one state in competition for the High Portable or High Mobile Trophy.

AWARDS:

Certificates will be awarded in three categories:

1) Highest fixed or fixed portable station in each state, province, and country, with 1,000 or more points.

2) Highest station in each state operating portable from a county which is not his normal point of operation, with 1,000 or more points.

3) Highest station in each state operating mobile from 3 or more counties, with a minimum of 10 QSOs in each of at least 3 counties.

Plaques will be awarded to the highest mobile and portable stations in the USA who meet the above requirements for certificates. Additional awards will be issued where deemed appropriate.

ENTRIES:

Logs must show category, date/time in GMT, station worked, band, exchanges, QSO points, location, and claimed score. All entries with 100 or more QSOs must include a check sheet of counties worked or be disqualified from receiving awards. Enclose a large SASE if results are desired. Logs must be postmarked by September 3 and sent to: CW County-Hunter's Net, c/o Jerry Burkhead N6QA, 7525 Baltic St., San Diego CA 92111.

ARMADILLO RUN

Starts: 0001 GMT July 30
Ends: 0200 GMT August 1

The Texas DX Society announces its contest to assist CW operators in gaining USA-CA All Counties Award status. The TDXS will activate all Texas counties by dispatching mobile stations from Houston and activating these stations during the County-Hunter's CW Contest. Several fixed stations will also be activated. To ensure that the largest number of entrants receive equal opportunity to work the mobile stations, operating will generally be restricted to 20 meters.

Entry class for the Armadillo Run is single operator from out of Texas only. Operators must operate from their own station. Mobile operation will generally be restricted to 14055-14075 MHz. Operation on other bands will be in accordance with the County-Hunter's CW Contest rules. During the contest, call CQ TDXS on 14050, 7085, or 3585 and a control station (W5DOZ, K5NA/2, N6HUP) will answer your call and try to answer questions. Information regarding which station will activate specific counties may be received by writing or calling KZ5M between 6:30 and 8:00 pm CDST at (713)-343-1060.

EXCHANGE:

So as not to distract from the County-Hunter's CW Contest, use the same exchange as that required by that contest; QSO number; category (P-portable, M-mobile); RST; state, province, or country; and county for USA stations.

SCORING:

The contest score will be equal to the total number of Texas counties contacted during the contest period. Ties will be broken by the Texas QSO count.

AWARDS:

A unique plaque will be awarded to the station operator contacting the most Texas counties during the contest period. The plaque winner will be flown to Houston for the 1983 ARRL National Convention to receive the award if he contacted over 175 Texas counties. Certificates will be awarded to entrants contacting at least 50 counties. Endorsements will be issued for the following county levels: 100, 150, 175, 200, 225, and 250, as well as All Texas Counties.

ENTRIES:

To qualify for award consideration, log information containing Texas stations worked, time (GMT), band, and the county the station was operating from shall be sent to: the Armadillo Run Chairman, Dennis Motschenbacher KZ5M, PO Box 82, Thompsons TX 77481. Mailing deadline is August 31, 1983. Entrants may forward QSLs to the above address for Texas QSOs made during the contest period. The TDXS will make special efforts to ensure that QSLs received are answered!

JORDANIAN AWARDS

The Arabian Knights Awards

This award is issued by the Arab Radio Amateur League (ARAL) members and presented by His Majesty King Hussein (JY1) of Jordan.

To qualify for this recognition of achievement, amateurs must have proof of having contacted at least ten Arab countries, and one contact must be with either JY1 or JY2. All contacts must be made on or after January 1, 1971, on any authorized mode of communications. There are no special endorsements.

To apply for the Arabian Knights Award, the applicant must prepare a list of claimed contacts in prefix order. Each entry must also include the date and time in GMT, the band and mode of operation, and the station worked.

Do not send QSL cards, as photocopies will be accepted. As an alternative, you may have your list verified by two local amateurs, a local radio club secretary, or a notary public.

Enclose this list along with an award fee of ten IRCs and send to the attention of: JY1 Award Manager, PO Box 1055, Amman, Jordan.

The Royal Jordanian Awards

To amateurs throughout the world who qualify, JY1, His Majesty King Hussein I of Jordan, will issue a very elegant award of achievement to recognize one of two levels of accomplishment.

First, the Silver Award is offered in recognition of having worked six different JY prefixes. There are no band or mode restrictions; however, all contacts must be on or after January 1, 1971, to count.

The second and probably the toughest award of all to obtain is the Coral Award, which is issued to amateurs who visit Jordan and make a QSO from Aqaba. Simple, huh? Anyone for a charter trip this winter?

As with all awards sponsored by our Jordanian friends, applicants must prepare a list of claimed contacts made, citing the usual logbook information including RS(T).

Forward this list, stating which award it is you are applying for, along with an award fee of ten IRCs to: JY1 Award Manager, PO Box 1055, Amman, Jordan.

DX AWARDS FROM ITALY

A very good DX friend of yours and mine, John Paul I8KDB, wrote a very complimentary letter about our awards column and asked that we share the awards

ARAB COUNTRIES

JY1	King Huaaain
JY2	Royal Jordanian Family
A4X	Oman
A6X	Unitad Arab Emirates
A7X	Qatar
A9X	Bahrain
CN	Morocco
HZ, 7Z	Saudi Arabia
J2	Djibouti
JY	Jordan
OD5	Labanon
ST	Sudan
SU	Egypt
YK	Syria
YI	Iraq
3V8	Tunlala
4W	Yaman
5A	Libya
5T5	Mauritania
60	Somali
70	South Yaman
7X	Algeria
9K2	Kuwait

program sponsored by the Associazione Radiotecnica Italiana (ARI). John Paul noted that the following general rules apply to all HF awards issued by the ARI and recommended that they be read together with the conditions governing each individual certificate.

All inquiries and/or applications should be addressed to the ARI Awards Manager, Giampaolo Nucciotti I8KDB, Via Francanzano, 31-80127 Napoli, Italy, and include 2 IRCs for airmail reply.

ARI awards will be issued to any amateur who submits a letter, dated and signed, with applicant's name, address, and call. He must certify that he has complied with all rules governing amateur radio in his country and that he has operated with fair play and good sportsmanship; he must include a complete list of QSLs, with callsign, date, frequency, reports, time, and type of emission (CW, AM, SSB, RTTY); and he must submit QSLs for checking. QSL cards must be submitted without corrections, erasures, or additions and must be clearly readable; include US $1.00 or 10 IRCs for foreign applicants. The Marconi Award is free; only a mailing fee is charged.

To get an award in a specific class, the cards must show the corresponding data in a clear format. Foreign applicants may avoid sending QSL cards by submitting a checklist of the cards duly certified by an appointed or elected official or a national amateur-radio-affiliated society or club. The ARI Award Manager reserves the right to check, on request, one or more claimed contacts, as necessary.

Certificato Del Mediterraneo (CDM)

The CDM is issued to those amateurs who can show confirmation of a two-way contact on the HF bands since June 1, 1952, with (a) one fixed station in each of at least 22 countries of the list shown below, and (b) at least 50 amateur stations located in peninsular Italy—an accumulated total of 72 QSLs.

The same station may be worked only once. Two classes of CDM are offered: mixed (AM, SSB, CW, RTTY) or phone only (AM, SSB). The minimum reports allowed to qualify are RS 33 and RST 338.

Countries list: Spain, Balearic Islands, Ceuta and Melilla, Morocco, France, Algeria, Corsica, Sardinia, Sicily, Lebanon, Egypt, Greece, Dodecanese Islands, Crete, Mount Athos, Turkey, Syria, Yugoslavia, Albania, Malta, Gibraltar, Cyprus, Monaco, Tunisia, and Libya.

Worked All Italian Provinces (WAIP)

This province award is issued to those amateurs who can show confirmation of a two-way contact on the HF bands since January 1, 1949, with one fixed station in each of at least 60 provinces of the Italian Republic for foreign amateurs, or one in each of 75 provinces for Italian amateurs. The same station may be worked twice or more if it's in a different province each time. Minimum reports acceptable are RS 33 and RST 338. Starting January 1, 1978, this award may also be endorsed for single band and/or for all 95 provinces.

List of Italian provinces: Agrigento, Alessandria, Ancona, Aosta, Arezzo, Ascoli Piceno, Asti, Avellino, Bari, Belluno, Benevento, Bergamo, Bologna, Bolzano, Brescia, Brindisi, Cagliari, Caltanissetta, Campobasso, Caserta, Catania, Catanzaro, Chieti, Como, Cosenza, Cremona, Cuneo, Enna, Ferrara, Firenze, Foggia, Forli, Frosinone, Genova, Gorizia, Grosseto, Imperia, Isernia, L'Aquila, La Spezia, Latina, Lecce, Livorno, Lucca, Macerata, Mantova, Massa, Matera, Messina, Milano, Modena, Napoli, Novara, Nuoro, Oristano, Padova, Palermo, Parma, Pavia, Perugia, Pesaro, Pescara, Piacenza, Pisa, Pistoia, Pordenone, Potenza, Ragusa, Ravenna, Reggio Calabria, Reggio Emilia, Rieti, Roma, Rovigo, Salerno, Sassari, Savona, Siena, Siracusa, Sondrio, Taranto, Teramo, Terni, Torino, Trapani, Trento, Treviso, Trieste, Udine, Varese, Venezia, Vercelli, Verona, Vicenza, and Viterbo.

Diploma Guglielmo Marconi (DGM)

This award celebrates the experiments carried out by Marconi in various parts of the world and brings them once again to the attention of radio amateurs. The DGM will be awarded to those who make contacts with the localities in which Marconi once conducted his experiments. To qualify, it is necessary to forward to the ARI all details of your contacts and a) 40 QSLs chosen from the list of contacts for DGM, or b) 35 QSLs chosen from the list plus the QSL from the official commemorative station, II4FGM, and one from any other G. Marconi memorial station, for a total of 37 QSLs.

When required (i.e., G = London, I4 = Bologna), the QSLs must indicate the city or region of the locality. The DGM is made available for AM, SSB, CW, RTTY, SSTV, and mixed modes. There is no band limitation; however, all contacts must be made on or after January 1, 1973.

QRP INTERNATIONAL

Being somewhat of a 10-meter QRP enthusiast, using a converted CB rig, I contacted Hugh Aeiker WA8CNN, who happens to be the Awards Custodian for the QRP Amateur Radio Club International. After hearing everyone on the band claiming to run QRP or QRPp, I figured once and for all I would get the true definition of these terms from one of the originators of an organized QRP group. Not only did I get this group's point of view as stated in their constitution and by-laws, but also I became the recipient of a full packet of information concerning their awards program.

It appears that this QRP fraternity, founded in 1961 by K6JSS, set the QRP standard to mean 100 Watts CW/AM or 200 Watts PEP input. As for QRPp status, we find the group recognizing this power only in the 5-Watt or less range. Now this is not to be confused with standards set by other QRP societies, such as the Michigan QRPp Club International, which also defines QRPp as under 5 Watts output, yet QRP is much less than 100 Watts.

As for their awards program, it is packed full of incentives, as you'll witness by reading on.

The main objective of the QRP ARC International Awards Program is to demonstrate the use of limited power which creates less QRM on the amateur bands, while still allowing us to enjoy the usefulness of the hobby. The club issues the following awards which are available to any amateur meeting the requirements as set forth for each below.

QRP-25

This award is issued to any amateur working at least 25 members of the QRP ARC International. Endorsements are issued for 50, 100, 200, and every additional increment of 100. To apply, send copies of logbook data, $1.00 or 5 IRCs, and a signed statement that you limited your power to 100 Watts input (200 Watts PEP SSB). Your list should also include the membership numbers of each station worked. There are no restrictions on band or mode recognition.

WAC-QRP

This award is issued to any amateur for confirmed contacts with low-power stations in all six continents. Power inputs again must be carefully adhered to and a statement must be made certifying the power was within rules governing the program. Keep in mind also that both your own station and the station you are contacting must be using QRP to qualify. Your QSL cards received must state the station's power used. Fee is $1.00 or 5 IRCs.

WAS-QRP

This WAS award is issued to any amateur using QRP power who contacts stations, one in each of the 50 US states, who are also using QRP power or less. Award fee is $1.00 or 5 IRCs. GCR apply.

DXCC-QRP

This DX award is issued to any amateur who utilizes QRP power and contacts 100 different countries, each of which must also be using low power as must be stated on their QSL card. To apply, send log data and $1.00 or 5 IRCs. GCR apply.

KM/W 1000-Mile-Per-Watt Award

This award is issued to any amateur transmitting from or receiving the transmissions of a low-power station, such that the Great Circle bearings between both sides divided by the power input of the low-power station equals or exceeds 1000 miles per Watt. Confused? Ah, it's not all that bad! Special endorsements are given for single-band or mode achievements. To apply, send copies of full log data including power used on both sides, signal reports exchanged, band and mode, and specific location of QTH on both sides. Include $1.00 or 5 IRCs. GCR apply.

DXCC-QRPp

Issued to any amateur for confirmed contacts with stations in 100 DX countries; power levels of 5 Watts or less must be used by the applicant. Reading the rules closely, I find no power restriction on the stations you must work. To apply, send log-book data, including power used and type of equipment used. Enclose $1.00 or 5 IRCs. GCR apply.

WAS-QRPp

Issued to any amateur for confirmed contacts with each of the 50 US states while operating 5 Watts maximum output. To apply, forward all pertinent log data and $1.00 or 5 IRCs to the Award Manager. GRC apply. Application for the award may be made when the first 10 states have been worked, with further recognition at the 20, 30, 40, and, finally, 50 levels.

As with all awards offered by the QRP ARC International, in order not to delay processing of your award, please furnish not only the data, but also the power levels used for each award and the type of equipment used.

All award applications should be sent to: Hugh Aeiker WA8CNN, 5 Keiffer Drive, St. Albans WV 25177.

• • • • •

My special thanks go out to Ade WØRSP/K8EEG, QRP editor for *CQ Magazine*, who recently provided me with the latest up-to-date information concern-

ing some very popular awards being offered by amateur fraternities.

DXCC-QRPp

This award, initiated in 1971 by the *Milliwatt: National Journal of QRPp*, offers a very distinctive challenge to dedicated QRPp stations the world over.

The award requires contacts with DX stations in 100 different countries of the world with the aid of list- or net-type operations. The rules clearly state that power must be limited to five Watts or less output. To apply, the applicant must submit a log in alphabetical order of callsign prefix of the station worked, indicating date, time, and frequency of each contact. QSL cards must accompany your listing and a signed declaration must be made as to the maximum power and type of equipment used. Application fee is $15.00 to help defray the cost of the large 30-inch engraved trophy.

DXCC Milliwatt

This award is also sponsored by the *Milliwatt: National Journal of QRPp*. The same rules apply for this award as for the DXCC-QRPp except that all indications of power level should read "under one Watt output." Applications are the same as for DXCC-QRPp.

The *Milliwatt* Field Day Trophy

Initiated in 1970, this trophy is awarded to the highest-scoring QRPp station in the ARRL Field Day event held each year in the month of June. To enter, you must submit an ARRL summary sheet, plus a listing of the stations you worked, band by band. You must state in your application the power level used, the type of equipment, and your method of measuring output power. If you use 1-5 Watts, you may multiply your score by four.

For power levels less than one Watt, you may multiply your score by 5. In addition, another 1.5 times your score may be added for operating your QRPp station independent of power mains. Another 150 bonus points are earned for full portable setup away from your QTH.

All three awards, the DXCC-QRPp, the DXCC Milliwatt, and the *Milliwatt* Field Day Trophy, are obtainable by making application to: Adrian Weiss WØRSP, 83 Suburban Estates, Vermillion SD 57069.

XV WORLD JAMBOREE MONDIAL

The Calgary Amateur Radio Association will be operating VE6WSJ from the site of the XV World Jamboree Mondial on July 1-16, 1983. The station will operate all bands and modes. Suggested frequencies: 7.030 MHz CW on the half hour; 14.190 SSB on the hour.

NATIONAL TOM SAWYER DAYS

The Hannibal Amateur Radio Club, Inc., will issue a third annual special certificate from the National Tom Sawyer Days celebration in Mark Twain's boyhood hometown, Hannibal, Missouri, on July 3-4, 1983. Hours: 1500-2100 UTC both days. Frequencies: phone—7.245, 14.290, 21.400, and 28.770; CW—7.125 and 21.125 MHz. Help us celebrate! To receive the certificate, send a large (8 × 10) SASE and your personal QSL card confirming the contact to Hannibal Amateur Radio Club, Inc., WØKEM, 2108 Orchard Avenue, Hannibal MO 63401. For further information, contact Tony McUmber at the above address or call (314)-221-6199.

SPACE DAY '83

The Cascades Amateur Radio Society (CARS), in conjunction with the Michigan Space Center in Jackson, Michigan, is offering a Space Day certificate to all stations who work WB8CSQ during Space Day activities. Look for WB8CSQ on 3.900, 7.235, 14.285, 21.360, and 28.510 starting at 0000 GMT July 9 through 1700 GMT July 10. A one-dollar contribution is asked to cover cost of postage and materials. Mail your log information and $1.00 to CARS, Space Day '83, PO Box 512, Jackson MI 49204.

USS COD

Having started in June, members of the Northern Ohio Amateur Radio Society will be operating daily through Labor Day from the *USS Cod*, a World War II submarine on permanent display at the port of Cleveland, Ohio.

Using the callsign K8KRG, NOARS members will be operating in the lower portion of the General band on 80 through 10 meters. Special Novice operations will be conducted on July 9 and 10 and August 20 and 21. On those dates, signals from the *USS Cod* will be found in the middle of the Novice band.

A special 8 × 11 certificate will be available upon request. Please send a QSL confirming the contact and $1 for handling and postage to WD8RZG, 8927 Torrance Ave., Brooklyn OH 44144.

ANNIE OAKLEY SPECIAL EVENT STATION

Again, it is the pleasure of W8UMD, the Treaty City Amateur Radio Association, Inc., to bring you the Annie Oakley Special Event Station from Greenville, Ohio, on Saturday, July 30, and Sunday, July 31, 1983. We will be operating from the Garst Museum which houses two rooms of memorabilia, guns, trophies, and costumes of "Little Sharpshooter," the name given to Annie by Chief Sitting Bull. Operating times will be 1400 to 0100 UT on Saturday and 1400 to 2200 UT on Sunday. Frequencies will be 20 kHz up from the General phone portion of the 40- and 20-meter bands, with excursions into the Novice segments of 40 and 15 meters. Your QSL and an SASE to TCARA, PO Box 91, Greenville OH 45331, will bring you a beautiful certificate and a pamphlet about Annie Oakley.

DETROIT ARSENAL

The Tank-Automotive Command ARC will operate W8JPW on 30 July 1983 from 1300-2000Z to commemorate the 42nd year of the Detroit Arsenal, home of the nation's first defense plant and the US Army Tank-Automotive Command. Frequencies: phone—7.250-7.274, 21.400, and 146.49 MHz; CW—7.055 from 1500-1700Z. Please put your QSO number and frequency on upper left-hand corner of your outer envelope. For an unfolded certificate, send a 9" × 12" SASE to: W8JPW, US Army Communications Command, Attn: CCNC-TAC-M, 28251 Van Dyke, Warren MI 48090.

BIX BIEDERBECK

The Davenport Radio Amateur Club will operate WØBXR to commemorate the great jazz player Bix Biederbeck and the city of Davenport during the Bix Biederbeck Memorial Jazz Festival, from 1600Z July 30 to 0300Z July 31, and from 1600Z to 2300Z on July 31. Operation on phone and CW, all bands about 10 kHz up from lower end of General-class band edges. To receive a certificate, send a large SASE to DRAC, c/o David Johannsen WBØFBP, 2131 Myrtle St., Davenport IA 52804.

LINCOLN BOYHOOD MEMORIAL

The Pike County Amateur Radio Club will operate station W9CZH from the Lincoln Boyhood Memorial, Lincoln City, Indiana, from 1700Z July 30 to 1700Z July 31. Special QSLs will be issued for your QSL and an SASE to Richard Bailey KC9VH, Box 311 RR 1, Winslow IN 47598. Frequencies will be: 3.925, 7.265, 14.305, and 21.395 phone; 14.090 RTTY; 146.52 FM; and 7.133 CW.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
c/o 73
Peterborough NH 03458

I'm going to start out this month by answering a question I raised last month, one that I'm sure has been just burning in the minds of many of you. Just what does Mr. Ferrell do with stations lacking a callsign in the alphabetical listings in his new *Guide To RTTY Frequencies*?

Well, shortly after last month's column was put to bed, I received a full copy of this new book, and I now can tell you the answer—they are not included in the alphabetical-by-callsign list. Only those stations with callsigns are! Reviewing the pages in the missing signature also shows a neat, short treatise on callsign origins and some other trivia in the same vein. Makes a good bit of reading. The second edition *Guide To RTTY Frequencies* is available from Gilfer Associates, Inc., PO Box 239, 52 Park Avenue, Park Ridge, New Jersey 07656, for $9.95. As always, plug this column when you write, ok?

Never in all my wildest expectations did I anticipate the veritable flood of responses to my offer of a 6800 and/or 6502 RTTY terminal program. In the past, several such comments have drawn but a lukewarm response, but not now! With more letters received than on any other single topic in the more than six years of this column, over half of the letters pleaded for 6800 software, with the majority of the others backing the 6502-based Atari 400/800. Let's take a look at a sample of what some of you said.

Philip Deem K9PD, Indianapolis, Indiana: "Let me identify myself as one of the very interested 6! (people worldwide interested in the 6800). I do, however, disagree that the 6800 is a dead system. This is possibly the only microcomputer ever offered whose purchasers have been able to make relatively inexpensive mods to remain current with the state of the art."

Horace Hall WB4OGM, Peterson AFB, Colorado: "In response to your request for comments . . . I, for one, would certainly be interested! I really don't think the 6800 is dead, though the ham fraternity may wish to hear more about the department-store computers since they are so readily available and the prices are so good. If all is lost for the 6800 and the new department-store computers are what RTTY hams want to hear about, then *at least* choose one with an honest-to-gosh keyboard. After all, we are going to have to type on them to get our messages across, so let's try to do so comfortably."

Weldy Moffatt VE5NM, Regina, Saskatchewan, Canada: "Please don't set the 6800 aside. There are a large number of these machines about and most are in the hands of persons that like to get into the innards. The 6800 on the S-50 bus is the ideal machine for the hobbyist that wants to tinker with hardware and software."

Joseph Ryan WB5LLM, Florence, Mississippi: "About dropping interest in 6800-based micros: Stop! Please don't give up on 6800-based micros. 6800 assembly-language programs can be cross-assembled to 6809 language."

Nick Hulbert KG5N, Lubbock, Texas: "The 6800 with the S-50 bus is an experimenter's dream. A person who likes to build and add to his system can simply put whatever he wants on the 30-pin card and plug it in. In fact, if I want to go to the 6809 or even the 6502, I can get a CPU card to do this and plug it into my 6800 mainframe. A far cry from what you can do with some of the other machines (easily). I'm trying to say that the 6800 is *not dead* and there are a bunch of units out there."

John Davison WØZFN, Kirkwood, Missouri: "I am very much interested in anything you want to print on the 6800. It might be dead, but mine is very much alive! It is a D-1 Motorola evaluation board."

Thomas Hand WD4IUG, Louisville, Kentucky: "I am interested in a RTTY program for the 6800-type computer. I have an APF computer which I enjoy very much."

Of course, not everyone is so universally behind the 6800 as the ideal CPU. For example. . .

Howard Busson W8WGB, Akron, Ohio: "I quit reading your column when you got off on the 6800 kick. I would suggest that you lean more towards the el cheapos (like the color computer)."

Stephen Carter KØGVZ, Rifle, Colorado: "It is truly unfortunate that the market did not support the 6800-6809 microprocessors, because they were easy to program and had really quite elegant architecture. However, realities being what they are, I suspect that any article based on a 6800 would have an extremely limited audience. On the other hand, if you used the Timex-Sinclair, VIC-20, Atari, or Radio Shack Color Computer, the low prices of

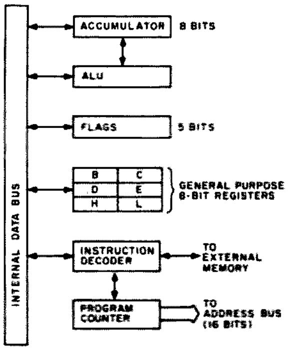

Fig. 1. 8080 block diagram.

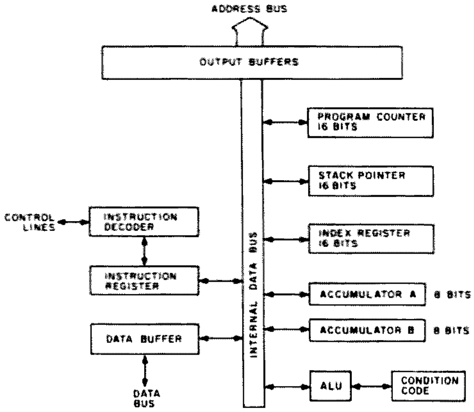

Fig. 2. 6800 block diagram.

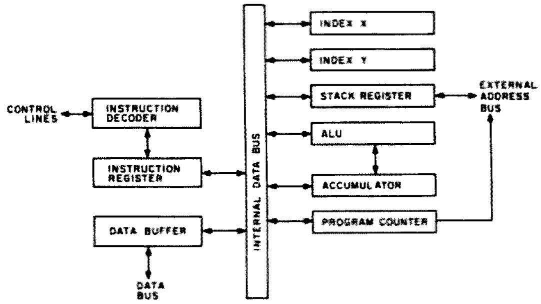

Fig. 3. 6502 block diagram.

these computers would make it feasible to buy one and dedicate it only to ham radio." I might point out to Steve that the CoCo *is* 6809-based.

James Theisen WB8REH, Gaylord, Michigan: "I am trying to understand machine code and hope to write or modify an existing RTTY program for the Pet." Stay tuned!

Rich Gehle N4DPQ, Nicholasville, Kentucky: "If you are considering a program for Atari on RTTY, please go for it. The present program is so restrictive and inconvenient, we are looking for relief."

It occurs to me that, to a large extent, a good deal of the above may be beyond the ken of many readers. 6800, 6809, 6502, 8080, Z-80—these are the substances of articles in *Byte* or *68 Micro Journal*, material rarely consumed by the average amateur. The truth is, for most commercially-available systems, the software offered is far more important than the central processing unit, or CPU, which is what all those numbers above were all about. But, if we will be writing software, we are going to have to commit to a particular CPU, or at least a similar group. Perhaps a look at history will be revealing.

In the beginning, there was no microprocessor, only big computers with tubes or discrete solid-state devices. After much work, trying to produce a general-purpose calculator integrated circuit, the Intel 4004 was born. This four-bit handler was the forefather of today's microcomputer breed. The next step was increasing the data capacity to eight bits, and the 8008 was born. I still remember the Mark-8 computers, home-brewed to use this chip in the early 1970s. An updated 8008 was introduced by Intel in 1973, called the 8080, and within two years the microcomputer revolution was off and running.

The design philosophy of the 8080 was an attempt to implement a calculator-type architecture on one chip, tracing back to the 4004 roots. Six general-purpose registers, stack and program counters, and a flag register work with one accumulator to provide internal data manipulations. Input and output is directed over special I/O channels. A block diagram of the Intel 8080 is shown in Fig. 1.

A year after the introduction of the 8080, Motorola presented its version of the eight-bit microprocessor, the 6800. Rather than the register orientation of the 8080, the 6800 is memory-oriented, that is, any memory location can serve as data, instructions, a register, or even an input/output device. By freeing up the organization, the 6800 becomes easier to program, and the more flexible addressing allowed by the 6800 makes this series, and ones to follow in this line, inherently more powerful. Fig. 2 shows the simple organization of the Motorola 6800, which contains two accumulators, an index register, stack and program counters, and condition code, or flag, register.

The next move was taken by several ex-employees of Motorola who joined forces with a calculator chip manufacturer, MOS Technology, to produce an enhanced 6800. The index register, a two-byte pointer in the 6800, was broken into two eight-bit index registers, and new modes of addressing were added. The B accumulator was discarded, and other refinements were made to some of the internal architecture. The result was the 6502, the block diagram of which is shown in Fig. 3.

The net result is that there are two major families among popular microcomputers: the 8080, with its enhanced version, the Z-80, and the 6800, 6502, and lately the 6809, an enhanced 6800, series. Although important differences exist between members of these groups, as a rule programs that are written for one may be translated, not always directly, from one to the other.

WAS YOURS BIG ENOUGH?

The middle of the summer provides a time for reflection and anticipation for the DXer. DXing is at its worst of the year, with high absorption on the higher bands and static and noise on the lower bands. So the DXer reflects on "the ones that got away" last year and anticipates the next DX season.

In fact, the weather might even be nice enough to entice the DXer away from static crashes of the rig and outside for a critical look at the skyhook.

Have you ever heard of a DXer who is totally satisfied with his antenna farm? Summer brings thoughts of a "real" antenna. A *big* one! Wouldn't it be great to be known as a Big Gun . . . to be first in the pileups!

Alas, the limitations of the lot, the neighbors, and the pocketbook seem to rule out instant Honor Roll status, but perhaps a small upgrading is in order. After all, the bands are only going to get worse over the next few years, and there are many more DXers today than at the last sunspot minimum in 1975-6. Competition will be intense. More antenna and refinement of operating skills are the only defenses against deteriorating sunspot numbers.

"If your antenna lasted the winter, it wasn't big enough," the saying goes. Unfortunately, there are many amateurs whose antennas were indeed large enough for this past winter. For them, summer brings the chore of rebuilding, perhaps a little better than before, and on a stronger tower, of course.

Now that we're all in the mood for some serious antenna work, I must share the following. Picture an amateur sitting at a desk, laboriously writing a letter to an insurance company:

"I am writing in response to your request for additional information in block number three of the accident-reporting form. I put 'poor planning' as the cause of my accident. You said in your letter that I should explain more fully, and I trust that the following details will be sufficient. I am an amateur radio operator. On the day of the accident I was working alone on the top section of my new 80-foot tower. When I had completed my work, I discovered that I had, over the course of several trips up the tower, brought up about 300 pounds of tools and spare hardware. Rather than carry the now unneeded tools and material down by hand, I decided to lower the items down in a small barrel by using a pulley, which fortunately was attached to the gin pole at the top of the tower.

"Securing the rope at ground level, I went to the top of the tower and loaded the tools and material into the barrel. Then I went back to the ground and untied the rope, holding it tightly to ensure a slow descent of the 300 lbs. of tools. You will note in block number eleven of the accident-reporting form that I weigh only 155 lbs.

"Due to my surprise at being jerked off the ground so suddenly, I lost my presence of mind and forgot to let go of the rope. Needless to say, I proceeded at a rather rapid rate of speed up the side of the tower. In the vicinity of the 40-foot level, I met the barrel coming down. This explains my fractured skull and broken collarbone. Slowed only slightly, I continued my rapid ascent, not stopping until the fingers of my right hand were two knuckles deep into the pulley.

"Fortunately, by this time, I had regained my presence of mind and was able to hold on to the rope in spite of my pain. At approximately the same time, however, the barrel of tools hit the ground and the bottom fell out of the barrel. Devoid of the weight of the tools, the barrel now weighed approximately 20 pounds. I refer you again to my weight in block number eleven. As you might imagine, I began a rapid descent down the side of the tower. In the vicinity of the 40-foot level, I met the barrel coming up. This accounts for the two fractured ankles and the lacerations of my legs and lower body.

"The encounter with the barrel slowed me enough to lessen my injuries when I fell onto the pile of tools and, fortunately, only three vertabrae were cracked. I am sorry to report, however, that as I lay there on the tools in pain, unable to stand, and watching the empty barrel 80 feet above me . . . I again lost my presence of mind . . . I let go of the rope."

So now you are forewarned! I came across this gem in the Kansas City DX Association's newsletter. W0FI's column, *The Preacher's Corner*, credits the Sterling-Rock Falls newsletter. Anyone know the author of this delightful piece?

Lloyd W6KG and Iris W6QL Colvin accept their 9K2QL license in the office of the Minister of Communications in Kuwait.

Seriously, antenna and especially tower work is dangerous stuff. Even a task as simple as changing the coax to the antenna can lead to life-threatening consequences. So take a little *extra* care the next time you climb your tower. Remember, the secret to DX success is longevity, not hardware. Live to DX another day!

Some of you have asked what happened to the DX column the last two months. A fierce relapse of the same pneumonia which curtailed my African DXpedition to 9L1CA, C5AAQ, and 6W8MM laid me low recently. Sorry about not being able to write the columns, and thanks for your cards and notes. I'll try to have some extra-special columns in the rest of the year.

NOTES FROM ALL OVER

Tahiti FO0 Did you work Jay or Jan O'Brien W6GO and K6HHD while they operated from Tahiti in 1982? The husband and wife team racked up nearly 9000 contacts in their two-week stay in FO0 last October, sponsored in part by the International DX Foundation. About half of the team's contacts were with stateside stations, and another quarter of their QSOs came out of Japan. Ten meters was their most productive band, producing about half of their contacts. The 9000 contacts included 128 countries! The O'Briens survived a misplaced antenna and 100-kph winds during their DXpedition. Jay writes, "Had we not lost our 40- and 80-meter antennas to the winds, our totals [on these bands] would be higher, as this is where the demand exists." Jay and Jan made more than 4000 contacts in the *CQ* WW SSB contest.

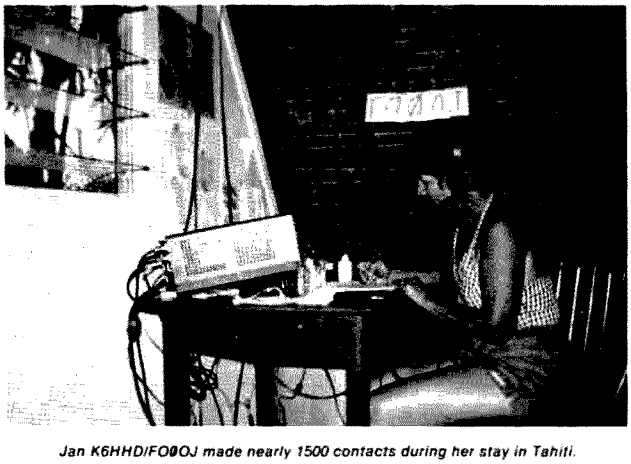
QSL cards for FO0OJ (QSL via Jan K6HHD) and FO0JO (QSL via Jay W6GO) have been sent out in answer to cards received. If you haven't received yours yet, try another card. Incidentally, Jay and Jan, who publish a list of QSL managers, *The W6GO/K6HHD List*, got their FO0 callsigns reversed in the advance publicity. No problem; QSL either call through Box 700, Rio Linda CA 95673.

Lloyd W6KG and Iris W6QL Colvin made another Yasme-backed DXpedition this past year, hitting, among other places, Saudi Arabia, Qatar, and Kuwait. They report:

Saudi Arabia HZ "We visited HZ1TA and HZ1TC in the capital of Riyadh, which is a large modern city. It is unusual in that it is not uncommon to see stores closed, with many items that they sell left in front of the store unguarded. Also, stores can occasionally be found open with no attendant present. One reason for this is that the people are very religious, and secondly, if a thief is caught, his hand is cut off! We also visited HZ1AB in Dhahran. There are 30 operators there, and they agreed to let us make a Yasme DXpedition for the two days of the ARRL International CW DX Contest, 19-20 February, 1983. We made some 1500 QSOs in that period, with four of the regular operators helping. All QSLs for HZ1AB for these two days should go to Yasme, PO Box 2025, Castro Valley CA 94546."

Kuwait 9K2 "Our next stop was Kuwait, where we were extremely fortunate to re-

Jay W6GO/FO0JO installs the tribander at Moorea.



Jan K6HHD/FO0OJ made nearly 1500 contacts during her stay in Tahiti.

ceive the special call 9K2QL. This is the only special call issued to visiting amateurs in a long while. The first few days we stayed at the Marriott Hotel, which is a converted ocean liner, similar to the *Queen Mary* in Long Beach. The problem of operating there was that the portholes could not be opened and there was no way to get the coax line into the stateroom. We finally moved to one of the chalets nearby. We convinced the manager that our 3-element beam would be a desirable addition to the swimming pool and garden area of his 5-star hotel! We made 6500 contacts with amateurs in 125 countries from 9K2QL."

Qatar "Qatar is similar to Oman because it is a recently rich oil country with tremendous new expansion. Although the treatment of women here is more liberal than in the past, only approximately 5% of the people seen on the streets or in the restaurants of the modern city of Doha are women. The biggest supermarket in town has one day set aside just for women and their families. It is not felt appropriate to have single men and single women go shopping together!

"For the first time ever, we operated from a skyscraper building. Our antennas were located on top of a 14-story hotel with a perfectly clear view in all directions. The great height seemed to help us both on transmission and reception; we averaged consistently about two QSOs per minute while on the air. In three weeks of operating, we made 8000 QSOs with amateurs in 135 countries, on both SSB and CW, 10–40 meters.

"Visiting personnel of all kinds, especially radio amateurs, are not encouraged to visit in the Arabian countries. We are extremely grateful to Mike A71AD who has helped us enter and operate in several Arab countries."

CORRECTIONS

The fine photographs in my article "Build this Classic Transmitter" in the May, 1983, issue were taken by Steve Finberg W1GSL. It is with regret that I notice due credit was inadvertently omitted from the published article.

Penn Clower W1BG
Andover MA

In the time since publication of "Confessions of a Counter Evolutionary," in the August and September, 1982, issues of *73*, several errors have come to my attention. Some corrections were listed in the October, 1982, issue on page 142. The following is a list of the remaining known corrections:

Table 1: IC10-11 goes to IC1-1, not IC1-38.

Fig. 7: IC10-11 should be 20 Hz to IC1-1, not 50 Hz.

Fig. 7: IC3 is actually wired as IC2-7 to IC3-14, IC3-12 to IC3-1, and IC3-11 to IC5-15.

Fig. 11(a): IC24-8 to IC13-4 is correct, but the connector is not "E". Delete "E".

Fig. 13: "PM" IC23-4 connects only to IC14-12, not to IC36-1 and not to IC23-12.

Fig. 13: Gate omitted from schematic:

Fig. 16: IC36-1 should not connect to "PM", but to IC20-8, as above.

Fig. 16: Input to IC18-1 should be IC3-14, not IC1-3.

Fig. 23: IC13 is a 74C74, not a 4013.

Part I, page 107, column 1, line 11 reads: "A 50-kHz signal is picked off the TBOD chain." Replace with: "A 100-kHz signal is picked off the TBOD chain. Because the gate control circuit, Fig. 11(a), operates on a 50% duty cycle, the 100-kHz signal becomes, in effect, a 50-kHz clock."

IC24-1,2,3 is an unused gate.

Thanks to WA1CST/7 and K2SHL for pointing out several of the above errors.

Display-Scan Modification

After a year of heavy use, the prototype WA2FPT counter blew a 75491 segment driver chip. It was replaced, but the new one failed after only a few weeks. I discovered empirically that Texas Instruments brand 75491 devices work more reliably in the published display scan circuit (see part I, page 105, Fig. 9) than National or ITT chips.

Sound engineering design practice should minimize such vendor dependency for circuit reliability, so I relented and added eight 10-Ohm, 1/4-W resistors, each in series with one of the eight segment lines to limit the current from the 75491 segment drivers, IC21 and IC25.

The resistors are mounted on a DIP header, socketed directly below IC35 and designated H2. See part II, page 52, Fig. 23. The resistors are mounted like this:

Here are the wiring changes for the display-scan modification.

SIGNAL	*AS PUBLISHED*	*MODIFICATION*
Segment a	IC25-9 to CONN-16	IC25-9 to H2-1 H2-16 to CONN-16
Segment b	IC25-6 to CONN-15	IC25-6 to H2-2 H2-15 to CONN-15
Segment c	IC25-2 to CONN-14	IC25-2 to H2-3 H2-14 to CONN-14
Segment d	IC21-13 to CONN-13	IC21-13 to H2-4 H2-13 to CONN-13
Segment e	IC21-9 to CONN-12	IC21-9 to H2-5 H2-12 to CONN-12
Segment f	IC21-6 to CONN-11	IC21-6 to H2-6 H2-11 to CONN-11
Segment g	IC21-2 to CONN-10	IC21-2 to H2-7 H2-10 to CONN-10
Segment D.P.	IC25-13 to CONN-9	IC25-13 to H2-8 H2-9 to CONN-9
Scan rate	IC6-15 to IC1-39 (1 kHz)	IC2-7 to IC1-39 (100 kHz)
Scan reset	IC10-11 to IC1-1 (20 Hz)	IC6-15 to IC1-1 (1 kHz)
D.P. clock	IC2-7 to IC18-1 (100 kHz)	IC2-15 to IC18-1 (1 MHz)
No name	IC35-7 to GND	IC20-6 to IC35-7 IC27-4 to IC20-4,5

The last four wiring changes altered the original scan display cycle to eliminate the 20-Hz flicker. The "no name" signal change resulted in the addition of another gate to Fig. 16:

Thank you for the favorable responses. If there are other errors or problems "encountered," please write and I will make every effort to resolve them.

NEW PRODUCTS

ELECTRONIC SOLDERING SYSTEM

The new Electronic System 9000 temperature-controlled soldering system from the Ungar Division of Eldon Industries enables a tip temperature to be varied from 420 to 800 degrees F with an accuracy of ± 10 degrees.

Solid-state circuitry, including microcircuit chips, samples the tip temperature 120 times per second. LEDs on the temperature-controller instantly display each 20-degree temperature increment reached, creating an illuminated bar chart that clearly represents the tip temperature to within ± 10 degrees F.

Ungar's recently announced Thermoduric™ heating element, which combines a highly efficient heater and sensitive tip-temperature sensor, recovers tip temperature after each solder joint in less than one-half the time of other systems. The smaller heating element also makes possible a micro handle that is cooler than other models.

Electronic circuitry in the controller prevents tip-temperature overshoot that could easily cause faulty solder joints.

The controller can be calibrated by a front-panel adjustment, using room temperature as a reference. For ultra-precise soldering, any temperature within the temperature range can be calibrated to be accurate within ± 5 degrees F.

Following the modular concept of Ungar irons, the controller is separate from the soldering-iron holder assembly. The controller can be mounted on a wall, side of a bench, or other convenient location. A tray, useful for holding parts or small tools, is exposed on the stand when the controller is removed. The iron holder can quickly be changed to the left or right side of the stand.

The system is electrically conductive from the tip to a grounded wall plug to prevent static electricity damage to microcircuits.

Further information is available from *Ungar, 100 W. Manville St., Compton CA 90220; (213)-774-5950*. In Canada: *Eldon Industries of Canada, Markham, Ont. L3R 1H5, Canada; (416)-495-9407*. Reader Service number 483.

CONTROL CHIP

Digital Microsystems, Inc., a Massachusetts-based firm which has been active in the microcomputer and software business for seven years, has announced a family of custom-integrated circuits aimed primarily at the amateur and hobbyist markets. The integrated circuits make use of the latest in sophisticated Large Scale Integration (LSI) technology. Each is designed to be tailored to its application by the user through a wide range of programmable features. The first product to be announced is a single-chip repeater control circuit designed to meet amateur and industrial needs for low cost, high reliability, and high performance control of repeater stations. The new chip will be offered initially in commercial and extended temperature versions. A full military device is planned.

The single-chip repeater control features crystal-controlled timing accuracy for ID, tail, and time-out timers. The period of each timer is programmable by the user. In addition, each chip features an audio generator for generating the repeater station's callsign as well as several useful control messages such as "TEST" and "PF." The chips are equipped to interface directly with PL decoders and also feature a PL enable input.

Additional features include a tune input for holding the transmitter on while making adjustments, a "force ID" input for manual trigger of an ID sequence, user-selectable Morse code transmission rates, and compatibility with a planned autopatch controller.

For additional information, contact *Digital Microsystems, Inc., 607 Sudbury St., Marlboro MA 01752*. Reader Service number 484.

HEIL TRANSVERTER

A unique 2-meter-to-10-meter linear translator has been introduced by Heil, Ltd. This new product allows a transceiver covering 144.00 to 146.00 to transmit and receive from 28.00 to 29.70 MHz. The translator is limited to a 1-Watt input.

The model 210 is primarily designed for use in the 29.30-to-29.70-MHz FM mobile band, using a 1-Watt handie-talkie or mobile transceiver for excitation, but it is also usable on SSB, CW, AM, and RTTY by exciting with an all-mode 2-meter rig. The model 210 has three SO-239 connectors on the rear panel—a 2-meter 1-Watt input, a 2-meter antenna, and a 10-meter antenna. With the front-panel function switch in the Out position, the 2-meter antenna is connected to the 2-meter transceiver or handie-talkie. Switching to the In position will cause the transverter to operate and produce a signal in the 10-meter band. The receive sensitivity is .3 uV for 10 dB quieting. The output power is approximately 4 Watts out at 29.60 MHz.

For more information, contact *Heil Sound, Ltd., Heil Industrial Blvd., Marissa IL 62257*. Reader Service number 480.

AUTOPATCH AND DTMF DECODER MODULES

Hamtronics® recently released two new modules to complement their line of VHF and UHF repeaters. The Autopatch Module provides full telephone patch and reverse autopatch functions for a repeater or duplex rural radiotelephone installation. In addition, it allows primary repeater control via phone line *and* secondary control via the repeater receiver, and it allows a control operator to monitor the repeater receiver by telephone even when the transmitter is shut off.

The Autopatch features a choice of either automatic answer or on-air tone ringing when a party calls the reverse patch function. It also features automatic level limiting, time-out timer, tape-receiver relay for logging, and access-code-tone muting for security.

The DTMF Decoder/Controller Module can be used with the Autopatch, or it can be used alone for control of repeaters and other devices by radio link. It has outputs to control two on/off functions independently. Typically, it is used to control a repeater and autopatch, but there are many other remote-control jobs it can perform in radio, industrial, mining, and scientific applications. The decoder uses a four-digit DTMF code, and several safety features are provided for security against falsing or tampering. The unit is all solid-state (no relays) and uses commonly available ICs.

For more information, ask for *Autopatch Data Sheet* and a complete free catalog including information on transmitters, receivers, converters, repeaters, etc., contact *Hamtronics, Inc., 65F Moul Rd., Hilton NY 14468-9535; (716)-392-9430*. (For overseas mailing, please enclose $1 or 4 IRCs.) Reader Service number 482.

TVRO RECEIVER

A TVRO receiver was introduced recently at the Satellite TV Trade Show by Gillaspie and Associates, Inc., of Sunnyvale, California. The Gillaspie 9600 completes the manufacturer's uniquely-designed six-foot system package—the first in the industry to offer a combination of optimized components that are each clearly defined and made to work with each other.

The receiver introduces several new features, including an infrared remote-control channel selector, customer-oriented controls, built-in polarity switching and tuning, and state-of-the-art video demodulation circuitry. Its design includes a walnut wood cabinet.

Gillaspie and Associates, Inc., expects to be able to manufacture 10,000 to 20,000 receiver units a month by the end of 1983. The product will be distributed through the company's exclusive distributors—North American Satellite Antenna in Fresno, California, Nevada Satellite in Las Vegas, Nevada, Satellite Communications Corporation in Silver Lake, Kansas, and Multivision in Oak Ridge, Tennessee—and a network of 800 dealers.

For additional information, contact *Gillaspie and Associates, Inc., 365 San Aleso Ave., Sunnyvale CA 94086; (408)-703-2500*. Reader Service number 485.

HF/VHF ANTENNA LINE

Ten-Tec, Inc., the amateur/commercial radio transceiver manufacturer of Sevierville, Tennessee, has just announced acquisition of the Bassett antenna line. The new Ten-Tec antenna line includes both multiband fixed-station and single-band mobile antennas.

The fixed-station trapped dipole antennas are offered in 13 models of two, three, four, and five band systems covering 10 through 75 meters. All models use helium-filled traps and baluns, stainless-steel hardware, and copperweld wire. Each model operates as a fundamental broadside dipole, band change is automatic, and no tuner is required to achieve vswr of 1.5:1 or less. Power ratings are 2 kW PEP.

The single-band mobile whip antennas feature helical inductors sealed in helium-filled lower sections with stainless-steel top whips. Models are available for all bands from 2 through 75 meters. Average weight is just 6 oz., yet they remain vertical and resonant at all highway speeds and are impervious to weather. Power ratings are 750 Watts PEP.

Accessories include a single-hole 5/8" fiberglass Mobile Deck Mount and a noninductive 5-band switchable Mobile Matcher to match 3-30-MHz mobile antennas to 50-Ohm coax. The balun, which features a helium-filled high-efficiency air core rated to 5 kW PEP, is also available separately, as are the helium traps for 30 meters.

The new acquisition also permits Ten-Tec to supply custom commercial mobile and fixed-station antennas.

For complete information, write *Ten-Tec, Inc., Sevierville TN 37862; (615)-453-7172*.

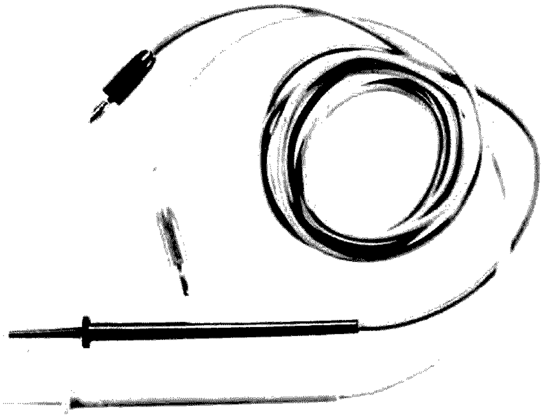
SWISS QUAD FOR 6 METERS

TET Antenna Systems announces its model SQ-61. The Swiss Quad is a two-element quad with both elements driven. The elements and the phasing line between them are made of aluminum tubing. The larger diameter of the tubing gives improved bandwidth over conventional wire-element quads. The elements are self-supporting, thus eliminating the usual support structure. This makes a lightweight antenna with low wind resistance.

The gain is higher than a 3-element yagi, but the turning radius is half that of a yagi. It is ideal when space is restricted. Both elements have trombone sections so they are easy to tune to favor any part of the band. Both elements are grounded to the boom, giving static discharge and lightning protection. The feed system matches 50-Ohm coaxial cable without need for a balun.

For further information, contact *TET Antenna Systems, 1942E W. Mission Road, Escondido CA 92025*. Reader Service number 477.

Yaesu's FT-726R multi-mode transceiver.



New test leads from Non Linear Systems.

FT-726R TRIBAND MULTI-MODE TRANSCEIVER

Yaesu Electronics Corporation has announced the availability of the FT-726R, the world's first amateur HF/VHF/UHF transceiver capable of full duplex operation for satellite work.

The basic FT-726R comes equipped for 2-meter operation on SSB, CW, and FM. Optional units may then be plugged in, enabling operation on 10 or 6 meters, 430-440 or 440-450 MHz on 70 cm. The optional SU-276 Satellite Unit allows crossband full duplex operation, for simultaneous uplink transmit and downlink receive operation on amateur satellites.

Controlled by an eight-bit microprocessor, the FT-726R features a dual vfo plus memory frequency management system, with independent frequency/mode storage on each vfo or memory; mode-inverting satellite transponders are therefore covered with ease. The transmit and receive frequencies may be varied during satellite work to allow easy zero-beat capability while following Doppler shift.

Equipped with many features found only on HF transceivers, the FT-726R includes an SSB speech processor, i-f shift, variable i-f bandwidth tuning, i-f noise blanker, RIT, multi-mode squelch, and a receive audio tone control. A CW filter, DTMF encoding microphone (YM-48), desk microphone (MD-1B8), external speaker (SP-102), and CTCSS units are all available as options.

For more details about the FT-726R, contact *Yaesu Electronics Corp., PO Box 49, Paramount CA 90723; (213)-633-4007.* Reader Service number 479.

TEST LEADS

Two test lead sets have recently been placed on the market by Non Linear Systems, Inc. They consist of flexible silicone rubber leads, 48 inches in length, with a rated working voltage of 1000 volts ac rms and a maximum of 10 Amperes.

Each type is terminated at one end with insulated stainless-steel prods which may be extended by more than two inches. Extension, retraction, or locking the prods is easily accomplished by rotating a knurled ring on the probe from left to right. Testing in remote circuit areas is easy through the extendable-prod feature.

P/N 51-160 test leads are terminated at the other end with standard banana plugs for use with the NLS Touch Test 20 series digital multimeters or other instruments with standard banana-plug receptacles. P/N 39-895 test leads are terminated with mini banana plugs for use with NLS LM-type meters.

Both sets of test leads are available nationwide from local NLS electronics distributors. For additional information, contact *Non Linear Systems, Inc., PO Box N, Del Mar CA 92014.* Reader Service number 478.

RECEIVER MULTICOUPLER

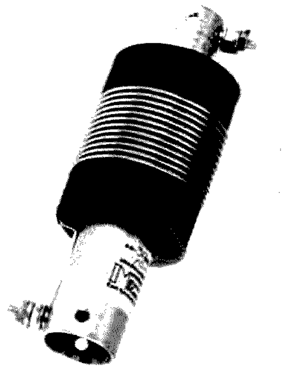
Two shortwave receivers may be operated from one antenna, thanks to a new multicoupler just released by Grove Enterprises, manufacturer of accessories for listening.

The CPL-2 multicoupler acts as a signal splitter, providing equal signal levels to two receivers simultaneously from one antenna.

Designed for flat response from 3-30 MHz, the inexpensive splitter comes equipped with interconnecting cables and adapters for different types of lead-in connections.

A scanner verison of the multicoupler is also available as model CPL-1.

For further information, contact *Grove Enterprises, 140 Dog Branch Road, Brasstown NC 28902; (800)-438-8155* (except NC). In NC, call *(704)-837-2216.* Reader Service number 476.



Microwave Filter Company's 30-meter antenna coil.

30-METER ANTENNA COIL

Microwave Filter Company has released its KW-30 antenna coil which allows trapped dipole coverage of the new 30-meter band. The resonant frequency is designed to provide a perfect half-wave dipole. The KW-30's power handling capability is 2 kW PEP, and the tensile strength is 800 pounds. An acrylic lacquer waterproof coating and all-aluminum hardware help to resist interface corrosion on the 5.5" × 1.8" coil.

For additional information, contact *Microwave Filter Company, Inc., 6743 Kinne St., East Syracuse NY 13057; (800)-448-1666.* Reader Service number 481.

REVIEW

VHF/UHF MANUAL

Well, old chap, brew up a spot of tea and settle in your easy chair. The *VHF/UHF Manual* is here from the Radio Society of Great Britain, and quite a good read it is.

Edited by G.R. Jessop G6JP, this is the fourth edition of the manual, and it includes the latest in theory and circuits for the modern experimenter's paradise. The book runs to a healthy 528 pages, which is somewhat larger than the last edition. Subjects range from propagation to space communications, hitting tuned circuits, antennas, and test equipment along the way.

The authors begin the book with a germane point—that VHF/UHF communications is no longer the arcane art that most amateurs believe it to be. Indeed, they suggest that those frequencies provided the backbone of some of Marconi's earliest experiments, and that in 1924, the magnetron made 900-MHz oscillation possible.

By the '30s, the basic techniques for these frequencies had been developed, and since that time, the progress of solid-state equipment has provided a more comfortable environment for VHF/UHF experimentation. And with the proliferation of 2-meter equipment, there is no longer any excuse for amateurs not to know their way around the rarified atmosphere of 144 MHz and above.

The chapter on propagation leaves no stone unturned in its coverage of the odd twists and turns of VHF/UHF signals. Since propagation here is dependent on the troposphere rather than the ionosphere, meteorology comes into play when attempting to understand how the VHF signal travels. For those not familiar with the ways in which weather is studied, appropriate concepts such as dew point, adiabatic changes, and vapor pressure are explained, with particular attention paid to their effect on communications. The more bizarre forms of propagation—sporadic-E, meteor trail, and auroral—also are explained, using current theory.

Fortunately for the reader, the authors make frequent use of visual aids and include real-world examples. This is an attribute I noticed throughout the book. Drawings are frequently provided in conjunction with the schematics, providing better insight.

The manual is not all theory, however; in subsequent sections, some good old down-to-earth construction projects are described. The construction-oriented chapters make up the bulk of the book, and they cover receivers and transmitters, converters, filter, microwaves, and test equipment. The authors' selection of circuits runs a wide range, from timeout timers and simple tube converters to synthesized 2-meter equipment.

With the continent's generally more stringent regulations concerning EMI, the circuits cited in the manual are considered to be fairly clean designs. As a homebrewer, I was also concerned about the availability of foreign components used in the circuits. But most of those included in the manual use standard European nomenclature for transistors, and a conversion chart can quickly give you the US equivalent. And regardless of where you are, an Ohm is still an Ohm.

Other projects offered include SSB equipment, ATV signal processors, and 144-MHz amplifiers. 432-MHz gear is also well represented, but because of the European focus of the book, relatively few opportunities for the 220-MHz buff present themselves.

The manual's treatment of antennas, the last refuge of the experimenter on a budget, is equal parts theory and construction; some sound design parameters are offered, but you are not likely to find any radical departures from tradition here.

Space communications, which may prove to be this decade's mode (as 2-meter FM was in the '70s), has been

somewhat slighted as well. The manual has provided the basic information on understanding, tracking, and designing amateur satellites, but little about the nuts and bolts of designing your own satellite station. To their credit, the authors included up-to-date information on Phase III, and the rapidly changing face of satellite communications may have forced the authors to be sparing in their suggestions.

Moonbounce has been relegated to a mere two pages of text—which is exactly where it belongs, for few hams have the money, space, or time to fiddle with the demanding requirements of EME.

Overall, this book is a winner, whether you want to home-brew your own VHF/UHF gear or just understand what goes on inside your black box. And as proof positive that this book is in tune with the times, many of the old tube circuits have been left in. No contradiction here: according to the editor, tubes are about 100 times less susceptible to damage from EMP radiation—which is one of the by-products of an atomic explosion.

For more information, contact the *Radio Society of Great Britain, 35 Doughty St., London WC1N 2AE, England.* Reader Service number 488.

GORDON WEST CODE TAPES

The concept of using tapes to teach the code is almost as old as the Morse code itself, and almost all of the variations of tape-taught code have been tried. I thought I had seen them all until I encountered Gordon West's Radio School code cassettes.

Gordon West WB4NOA has managed to come up with a new idea—his tapes are in stereo, with one channel consisting only of code and the other channel containing a voice translation of what is being sent. This is an interesting idea, particularly for the beginning student who needs to know if he is getting his characters straight.

The tapes I reviewed are for the first-time student who has no knowledge of the code. The four-tape series is divided into an equal number of 90-minute "modules," each representing a higher level of achievement (or difficulty, depending on how you look at it). The first two modules introduce the student to all of the letters, numbers, and punctuation marks in common usage. The remaining modules work toward reinforcing the previous lessons.

West begins lessons by introducing a few new characters, repeating them several times, and then sending a series of the new characters on one channel while identifying them in voice on the second channel. The purpose of the stereo is to allow you to listen to the code only and then go back and check your copy. Or, on your first round through that lesson, you can listen to both channels until you feel confident with the new characters being introduced.

Each lesson works gradually into more complex sequences. As more characters are introduced, the strings of letters become words and then sentences. The longer strings and sentences are not simultaneously translated on the voice channel. Instead, West identifies the end of each string with a period. This marker tells you to turn up the other channel for the voice translation of what was being sent.

Between lessons, West identifies possible trouble spots and offers tips to help beginners learn the code. From the sound and inflection of his voice, it is obvious that West has had broadcasting or announcing experience. His voice is easy to listen to and the script is delivered in an informal, chatty manner.

The tapes may also be played on a monaural system. The only difference will be that both channels will be played and you cannot blank out the voice-over as you can with a stereo cassette deck.

However, this compatibility with both mono and stereo systems is also one of the tapes' drawbacks. Since not all of the practice sessions are simultaneously repeated on the voice channel, the advantages of the stereo capability are not used to full advantage. Throughout much of the tape, the only difference between the West tapes and a standard mono tape is that you have to turn up the volume of one channel to catch the answers to the practice session.

After several hours of use on both stereo and mono tape players, I found that it was almost easier to listen to the tapes on the mono cassette player. The advantage to the separate channels occurs primarily when new letters are being introduced.

Another aspect of the West system which I did not like was the use of words and sentences. Unless random code groups are used, it becomes too easy to memorize the characters being sent rather than improve your recognition. After only a few trials on the tape, I could predict with fair accuracy the upcoming characters. Granted, I was not trying to learn the code at the same time, but the same process would occur at a slower rate with a beginning student.

West uses the standard system of teaching the code, beginning with the easiest characters such as i and e and progressing to the more difficult ones. Repetition—the key to successful memorization—is used to great advantage here. However, he does not send the characters themselves at a higher speed so that the student can get used to the sound of the code at 10 or 15 wpm. Time and again, it has been shown that this technique provides the best results because the student does not have to relearn the code each time he or she advances in speed.

I did not find that there were any clear advantages to West's stereo system. The tapes are professionally produced, and West has paid a lot of attention to the psychological factors of learning. His breaks are well-timed to coincide with the length of time most people can concentrate, and his informal manner to a certain extent overcomes the impersonality of tape-teaching.

But in his attempt to make the tapes compatible with both stereo and mono systems, West has somewhat weakened the effect of this novel technique.

West's code tapes list for $39.95 for a set of four. For more information, contact *Gordon West's Radio School, 2414 College Drive, Costa Mesa CA 92626; (714)-549-5000.* Reader Service number 486.

AEA'S KT-2 KEYER/TRAINER

OK, all you would-be General- and Extra-class hams out there—you no longer have any excuses for not upgrading. At least, not since the people at AEA camé out with their KT-2 keyer/trainer. The KT-2 is a flexible unit which doubles as a code-practice device (CPO) and a keyer. In short, it will not quickly outlive its usefulness.

As quality equipment should be, the outside of AEA's little black box is deceptively simple, with only an on-off/volume knob and a DTMF keypad as external controls. On the back, there are jacks for headphones, a key, and outputs to either cathode-keyed or grid-keyed transceivers. However, the many capabilities of the KT-2 belie its plain appearance.

As a training unit, the KT-2 has several special features of note to the person trying to move his or her code speed up to that elusive 13 wpm. One of these features is the optional use of the Farnshaw method of practice.

The Farnshaw technique has proven to be one of the most successful ways of learning the code. More commonly known as "fast" practice, the Farnshaw style consists of sending the characters at a fast speed—say, 15 wpm—while maintaining a longer inter-character spacing to create a lower overall speed. In this way, the student does not have to relearn the sound of the characters as he advances in speed. You can, therefore, program the trainer to send its random code at 10 wpm, while keeping the character speed at 20 wpm. Actually, the trainer has the capability of sending from 5 wpm to 98 wpm, with a character speed of up to 99 wpm. Not too bad for a little black box.

AEA's KT-2 keyer/trainer.

Pumping Iron

Coupled with this option is the ability to program the keyer to automatically increase the code speed during a training session. I dubbed this the "pumping iron" technique since it parallels the method used by professional body-builders to develop muscles. On power-up, the trainer is set to start out at 5 wpm and accelerate to 20 wpm over 10 minutes; as workouts go, that's nothing to laugh at. But through the keypad, you can adjust both the starting and finishing speeds as well as the duration of the session.

More programming gives you further options. If you prefer the traditional method, hitting two keys on the pad will give you the code at exactly the speed you choose—no reduced intra-character spacing and no acceleration. Or if, like me, you prefer to listen to 20-wpm characters sent at 13 wpm with no speed-up to overload you, that can be arranged, too.

Randomize, Don't Memorize

Nine pseudorandom sequences may be chosen, and no sequence will repeat itself until about 34,000 characters have been sent. Even if you manage to memorize all of those without bringing your code speed up to where you want it, AEA has provided an escape valve. Starting a practice session with the ***# sequence will randomly select your starting point.

The length of word groups may be random or 5 characters per group. And if you really want to get tough on yourself, the KT-2 is divided into two character sets—a common set which includes the alphabet, numerals, and six frequently-used punctuation marks, and a second set which includes CW abbreviations and little-used punctuation. Those with an intense desire to copy apostrophes and parentheses won't be left out.

Though the sequences of keys you have to press to program and begin the trainer look complex, I found that I had them down pat after only a few sessions. None of the commands take more than four keystrokes, and AEA thoughtfully provides an easily-used table for quick reference.

Another advantage to using the KT-2 is that, unlike on-the-air practice, you don't have to guess at the speed. The KT-2 is calibrated to be extremely accurate, using the PARIS method. The word "PARIS" has 10 dots, four dashes, nine intra-character spaces, four inter-character spaces, and one word space for a total of 50 code elements. In adjusting code speed—for different dot-space and dash-space ratios—PARIS is used as a reference to determine the actual speed of the code.

The Keyer

The KT-2 is no contest keyer, but not all CW buffs are contesters—and as a keyer, the KT-2 offers you the options you need most.

First of all, it can be used with an iambic paddle, a bug, or a straight key. With the latter two, you simply key the dash input and the KT-2 produces a sidetone. As a full iambic keyer, this unit shines. Both dot-space and dash-space ratios (weighting) are adjustable from the normal 3:1. And when you change the weighting, the keyer will adjust the output automatically so that you will be sending at precisely the speed you set.

The keyer sidetone (as with the trainer) is adjustable from its power-up frequency of 1111 Hz, and the KT-2 also has dot and

dash memories. The memories allow you to insert a dot in a string of dashes (or vice versa) just by squeezing the appropriate paddle. Without this feature, you would have to release the dash paddle, squeeze the dot paddle, and then key the dash side again. But if you prefer old-style sending, you can turn this option off.

And for tune-up, the keyer has a lock-on position which produces a solid tone while you fiddle with your finals. You can cancel the tone by hitting any button on the keypad.

The manual for the KT-2 is well-written. AEA provides an initial testing procedure to ensure that your unit is operating correctly, and the operating instructions are clear and concise. In addition, there is a complete schematic, parts list, and PC board layout. The unit uses a 12-V supply, and AEA sells a wall-plug adapter, a cigarette lighter cord, and a nicad pack to accompany it.

At the list price of $139.95, even Ted McElroy would have bought the KT-2.

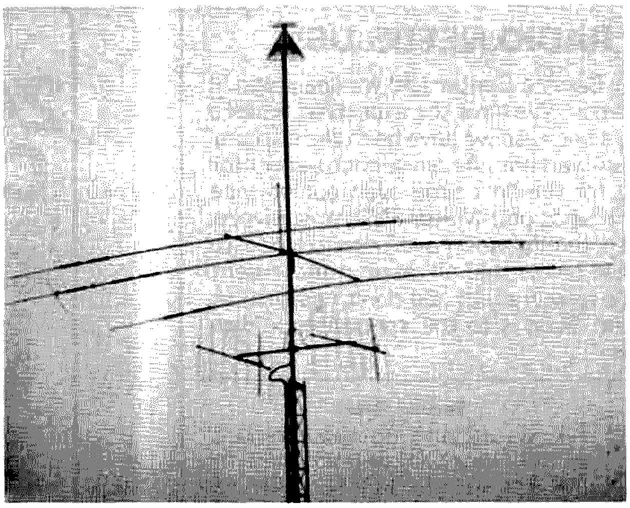
CUSHCRAFT A3/A73 TRIBANDER



AG9V's stack: 2 × 7-el/146 MHz at 67', the Cushcraft A3 at 70', and home-brew Discone for 144/220/450 at 80'. (Photo by K9JQE)

After years of helping to build (and use) other people's ham stations, I finally settled down and found a home that was compatible with ham radio. It didn't take long before a tower started growing in the backyard. No more semi-verticals and very random wires for me!

But having a tower meant that I had to find something to put on top of it—and monobanders were out (at least until next year!). I decided on the Cushcraft A3 triband beam with an A73 40-meter add-on kit. The A3 is a three-element beam for 10, 15, and 20 meters, and the A73 kit adds an additional set of traps and some length to the driven element so that the antenna will work as a rotatable dipole for 40 meters. With the A3/A73, I can cover four bands with one antenna and feedline, and that makes designing an antenna farm a lot easier.

The A3 is a small antenna with a boom length of only 14 feet, although the driven element (with the A73 kit installed) is about 35 feet long and uses a truss and cord to reduce element sag. The beam went together easily, and the instructions, which consist almost entirely of diagrams, were simple to follow. Element dimensions for use on the CW, phone, or mid-band segments are given so that the antenna can be tuned up in your favorite part of the band. I used the CW settings for mine.

The wind load of the A3/A73 is 4.94 square feet (4.63 sq. ft. if set up for 30 meters). The antenna is well built and should survive any reasonable wind.

After assembly, the crew (two on the ground and WA9SRW on the tower) hoisted the antenna up to its final resting place at 70 feet without any trouble. Some quick swr checks indicated that everything was as it should be, and off I went to work the world.

About a month after the A3 was installed, disaster struck. While operating with a kilowatt input on 20-meter CW, I watched with horror as the swr rose from its usual 1.1 to 1 up to 3+ to 1. After letting things cool down a bit, I tried again, this time using 100 Watts output. When first keyed, the swr was right where it should be, but I could watch it rise until, after about 45 seconds, it was back up to 3 to 1.

A check of other bands showed that 40 meters also was affected, but that 10 and 15 meters were not. This led to the suspicion (confirmed by a phone call to Cushcraft) that I had a bad 40/20-meter trap on the driven element. Analyzing the failure, it appeared that there had been an arc in the trap. The failure occurred on a damp, misty night, and apparently the moist air provided the path that began the arc-over. Cushcraft whipped up a modified set of traps with increased clearances that should eliminate any such problems.

Once the weather cooperated and we got the new traps installed (these things always seem to happen in the middle of winter!), everything was back to normal. Subsequent misty nights have proven to be no problem. Cushcraft has informed me that these modifications will be used in future production A3/A73s.

Now for the $64,000 question—how does the A3 perform? Considering the compromises that are inevitable in a multiband beam, the answer is very well indeed.

Let's look at the compromises first. There are two problems with a small, trapped beam. First, traps aren't 100 percent efficient and they do introduce some loss, but more important, they shorten the elements by adding inductance to the antenna circuit. Of course, this has the advantage of creating a smaller antenna, but it also means that like most shortened antennas, the bandwidth will be reduced and the swr curve will be sharper.

Second, the spacing between elements is a compromise—if the elements aren't too widely spaced for 10 meters, they will be closely spaced for 20 meters. Closely-spaced elements tend to reduce gain, front-to-back ratio, and bandwidth.

Gain and front-to-back bandwidths usually get narrower along with swr bandwidth, and particularly on 20 meters, these measurements won't be near their peak values at the end of the band away from where the A3 is tuned.

These compromises most affect the lowest frequency band in use, and on the highest band, performance should be very close to that of a full-sized beam. In practical terms, the trade-offs don't make a tribander (or in this case, a "quadbander") like the A3 an inferior performer, and they certainly result in a very practical antenna design.

The A3's swr bandwidth, most noticeably on 20 and 40 meters, is much narrower than that of a full-sized antenna, and if the A3 is tuned for CW, you'd better figure on dealing with a rather high swr at the top of the phone band. On 40 meters, in fact, the 2 to 1 bandwidth is only about 125 kHz. Narrow swr bandwidth itself isn't a serious problem unless your rig won't load into the mismatch—and that's what antenna tuners are for. According to Cushcraft, the A3 will handle a full kW if the swr at the antenna (and not measured through a transmatch) is less than 3 to 1. An swr that high should occur only on 40 meters.

In use, the A3 isn't noticeably inferior to a full-sized antenna. The gain on 20 meters may be a dB or two below that of a monobander, but it's still a lot louder than a dipole! I spend most of my operating time haunting the bottom end of 20 CW, and I don't feel that the A3 is a handicap. If a pileup is so huge that I can't get through, it would take a lot more than a bigger antenna to make much difference.

My CW-tuned antenna does have lower gain and front-to-back ratio at the top of 20 than at the bottom. Setting the elements to mid-band dimensions would tend to even things out, but at some loss of CW performance. This is where the monobander has the edge, and where an operator demanding optimum performance across the entire band might be unhappy with the A3 or with any small tribander.

Of course, if you get into the battles on 20 phone or if you contest in a big way, you'll need all the antenna you can get, but I think that most of us can live quite nicely with an antenna like the A3—particularly when you consider the cost of an A3 and the modest tower it takes to support it versus the cost of a stack of monobanders, a huge rotor, and a heavy, guyed tower. That ultimate dB is very, very expensive!

I haven't talked to many folks who use a tribander with a 40-meter add-on, so I was very interested in how the A3/A73 would work for DXing from the midwest, a couple of thousand miles further from the DX than are you lucky coastal types. My other 40-meter antenna is a half-delta loop over a pretty good ground. It seems to work very well, and I've worked a fair amount of DX with it.

Well, folks, the A3/A73 beats the half-delta every time. It hears less noise and seems to talk as well or better than the other antenna. The nulls off the end of the rotatable dipole are very noticeable, and it is possible to null out European broadcasters by 10 to 20 dB merely by rotating the antenna 90 degrees away from Europe.

Of course, having the antennas at 70 feet doesn't hurt any, and at a lower height, the dipole might well lose to the half-delta. But in any installation, the A3/A73 has an advantage because it puts the 40-meter antenna up where it can perform best. It will nearly always be installed as high as it possibly can be, and unlike most wire dipoles, it will be in the clear and away from guy wires and other antennas. Under these conditions, a dipole can do an amazingly good job on the lower bands, particularly since fewer of the gang are using beams on 40 meters.

Incidentally, the A73 kit may also be set up to cover the new 30-meter band instead of 40, so it's an easy way to add a new band to your station without a lot of hassle if you already have an antenna for 40.

The A3/A73 antenna will provide respectable performance on 40 through 10 meters without unreasonable cost or complexity. It's a good choice for the ham who has limited space and/or funds for antennas, yet who wants to be able to punch through a pileup now and again.

For further information, contact *Cushcraft Corp., PO Box 4680/48 Perimeter Road, Manchester NH 03108.* Reader Service number 489.

NEVER SAY DIE
editorial by Wayne Green

from page 8

After all, what's the real difference? Radio waves go everywhere, so from a radio point of view, it is of little consequence whether the operator is in Burma, Thailand, or Sri Lanka. For that matter, one of the best DXpeditions of all time, Heard Island, was done from up near Vancouver, Canada. Just think of the trouble everyone was saved on that!

When you move the DXpedition nearer the US like that, you don't let propagation or distance screw up the contacts. You save a fortune on boat charges and have a much lower chance of getting killed. You save weeks of sailing, a bunch of gas, and in every way cut costs enormously. And your QSL cards are as valuable as if you'd gone to all that silly trouble and expense.

No, today's DXpeditioners seem to have lost their spark of originality and imagination. Poor Lloyd and Iris Colvin had to go through all sorts of trouble to get into the Persian gulf countries and get on the air. It cost 'em a bundle, too. And for what? Just to give a few thousand of us a card from a new country...one which would have been infinitely easier to get if they'd operated from some place nearer home. All you need is to make the contacts, provide some good-looking documentation to the ARRL, and thousands of hams are happy as clams.

The first truly imaginative DXpeditioner is still with us. I see him almost every year at Dayton. He set up and gave us contacts from a bunch of African countries while happily sitting in Casablanca. Once he broke the ice, we saw many of the previous DXpeditioning problems solved. That did away with quite a few arduous boat trips, eased country restrictions, eliminated customs problems for equipment, and so on.

Why take a chance on braving the wild South Atlantic storms when you can save tremendous time and keep out of danger by operating from near Venezuela? That's where a pair of well-known DXers did it. And, you know, it isn't much easier to blast through pileups to Peter and Paul Rocks if they have been moved, for convenience, to Venezuela instead of the Atlantic. Those same Texas and Missouri DXers are still in there tail-ending for twenty minutes, alternating calls so no one can tell if the DX station is transmitting or not.

I say let's get more fun into DXing by going back to the old system. Let's get a nice little DXpedition for Spratly going...with the spoilsport ARRL chaps who are making people get killed on the boat out of Singapore and the rest of us out on Catalina Island running two Watts to a wet string.

DIGITAL PERSPECTIVE

Having gotten bitten by the digital bug some 35 years ago when I got involved with amateur radio teletype, I haven't had as much trouble getting into the digital revolution as many of the more conservative (tube-oriented) old-timers. And now we're reading about the marvels of digital audio, the coming revolution in compact laser-playing disks...maybe even digital television.

As much of a fan of new ideas and pioneering as I am, I'm not yet totally convinced about the laser disk idea. The basic idea of digital audio is great. With this technology it's possible to make recordings where you have zero noise from the recording medium. Yep, no tape hiss...zero. No record groove hiss, snap, crackle, and pop. The idea is just fine. And the technology makes it possible to extend the dynamic range of recordings from 60 dB out to 90 dB. Remember, if you will, that every three dB means a doubling of power, so that extra 30 dB will buy you a thousandfold increase in power capability. Whooey, thousand-Watt audio amplifiers?

Digital audio has some benefits and some drawbacks. For the audiophile, the results of DA are so spectacular that he has no choice but to go digital. But this means a lot of expense, because while digital disk players will work with analog preamplifiers and amplifiers, a purist would blanch at anything less than digital right on through to the speaker. Digital speakers? No, little of this technology has even been invented yet, but it will be along. This will be a wonderful area for small entrepreneurs to get going, working toward starting megabuck corporations on the coattails of yet another budding high-tech industry.

The messy part of this whole scam lies in that vaunted laser disk. The problem is that we're way behind on inventing storage media for data. We're still horsing around with round, flat records which have to be spun...a hangover from the early recordings of Edison. You'd think we would get the message on this when we see $3,000 record players. And even those aren't as good as the early model laser digital players. Look at all the agonies we are going through with Winchester disks for data storage in computers! It's almost time to start seriously working on a mass memory system which is not mechanical.

They're talking about being able to put laser disk players into cars. It's laughable. Do you know that the silly record player they've invented to play those four-inch laser disks has to change speed as you go from the inside grooves to the outside from 600 rpm down to 200 rpm? And once you know that, you realize that the speed of the record player has to be different for every single groove it plays. Talk about a mechanical monster!

We may have to use some mechanics to retrieve data from a transportation medium, but spinning a record at an infinite number of speeds doesn't seem optimum. Perhaps we can come up with a card which can be read as it moves by a reader, using a memory cache to smooth out the flow of data. Or we might want to go to some sort of optical/film data storage system which might give us higher density of storage than micro holes blasted in thin films of metal.

On the bright side, there's no way that cassettes will be able to handle the data storage requirements, so we may see a drop in the copying of records.

These are wonderful days for amateurs...and we should remember that most of the really important breakthroughs in technology have historically been made by amateurs. If you've worked in any R&D firms, you know why this is as well as I...and I've done my homework on this one, too. I worked for an R&D lab at one time and saw with my own eyes why virtually no significant developments in technology can emerge.

The key lies in the funding process. R&D labs do not hire people to do what is called basic research...at least few of them do. Basic research is experimenting for the hell of experimenting, with no commercial product in mind. We used to spend a lot of money this way before WWII, but when the war came we stopped this "wasteful" spending and only worked on projects where there was a good potential for results.

It's still this way. If the lab manager is able to convince management that there is an almost certain chance for a profitable product to emerge, the research funds can be found. Iffy projects are tabled. The amateur, of course, with no one to stop him, can work on anything his heart desires. And if he comes up with something fantastic, he's got it made. If not, well, at least he's had the fun of trying. This is why hams in the past have come up with most of the real breakthroughs in radio technology.

It's getting time to experiment over the air with some digital audio. We might even want to try some digital stereo and see what we can do with it. A sampling rate of 10 kHz might work out fine for our type of communications rather than the 44 kHz they use for high-fidelity music. That's a little broad, but, after all, we're just experimenting. We might be able to get that down to 6 kHz and still have better voice communications than we have now.

The objective is to get a maximum of information through for a given band of frequencies and a given time, so whether we find it better to do with a 50-kHz-wide band or a 2-kHz band isn't as relevant as the throughput. If we can digitize voice and then send it in short blasts at high speed with error-correcting, we could end up with a very efficient communication medium.

The world of digital audio is

just getting going. It is going to turn into an enormous business. Are you going to be one of the winners in this?

DENTRON

A piece in *Newsweek* a few weeks ago about a suit by Ron Hubbard's son to take over the Hubbard Scientology empire, claiming that no one has seen Hubbard for over two years and that he is presumed dead, brought to mind a recent rumor that DenTron had been bought by Scientology.

Having more than a casual interest in Hubbard and Scientology, I called DenTron to see what was up. Scientology has been getting a lot of flak of late, with exposés on television, books exposing it, and so on. Well, having been around when it began and having personally known Hubbard, I like to keep up with what's going on.

Scientology got started back in 1950 with the publication of an article in *Analog* magazine (science fiction). I'd been reading the magazine for many years and was particularly interested in an article on a new book being published by Hubbard on Dianetics, a new science of the mind. I got the book, started right in experimenting with some of the techniques described therein, and had some truly amazing experiences.

Hubbard's book was flamboyant and his claims extravagant, but since the fundamentals of it made more sense than any other approaches to the mind, I decided to look into it further. I took a six-week course at the Hubbard Dianetic Research Foundation in Elizabeth, New Jersey, and became an accredited Dianetic Auditor.

The school was fascinating. There was the element of baloney with the Hubbard claims of producing "clears" who had eidetic recall and were in most respects perfect people. We never saw anyone like that. But the concept was a good one and the techniques did produce the most incredible results in a hurry.

The story going around the school was that the whole idea for Dianetics was developed by someone else and that Hubbard had come across the manuscript for the work when the real author was in a hospital and died. So the claim went that Hubbard took the extensive research as his own, adding what he thought might result from the therapy—clears—as an accomplished fact.

Now Hubbard is, or was, a very magnetic person. He was a good writer and a persuasive BS artist. But the quick success of Dianetics seemed to distress him. It didn't take long before there were many people using the techniques from his book with more success than he enjoyed. Keeping in mind his enormous ego and the weight on him of the success of the therapy which he claimed to have discovered, I was not at all surprised when he came up with a new approach which was mostly his own. . .and which he called Scientology.

It's emotionally difficult to be a guru pretending something is your own when it isn't, so he came up with his own. This was cloaked as a religion, both as a way to get around laws against medical treatment by non-doctors and as a way of brainwashing the impressionable.

Having been at the HDRF, I remained on the Scientology mailing lists for years, getting their literature and receiving hundreds of letters suggesting I come in for updating. I kept answering all letters with the question: If you are able to really do such marvelous things, please show me one single example of a person who has been so improved by Scientology that he or she now stands out in some way over the rest of us. I never saw any indication that Scientology could even come close to Dianetics in effectiveness. . .and so no one seemed to emerge as outstanding in talents from the process.

Large numbers of Scientologists were used to write personal letters to prospective recruits. They had to write by hand. . . sincere. . .and encourage the correspondent to come in for a "test run."

One of the results of just about *any* type of mental therapy is the feeling that one has improved. Just as the sugar pill placebo given by doctors is capable of remarkable cures of some illnesses, the application of almost any psychotherapy seems to make some people feel better. Trading on this response, the Scientologists quickly get newcomers involved with their strange perception of reality, and they find it difficult to get loose.

Hubbard was able to build up his Church of Scientology into a multinational organization, with the headquarters at St. Hill, a huge estate in England. When governmental pressures from some countries grew too great, he moved his personal HQ to a converted cargo ship served by the elite of his group. I remember the glowing brochures asking for volunteers for this. Golly, the enthusiasm and excitement of those brochures was fun and almost too much to resist.

The church is now a large, rich organization with branches all over the world. And, I suspect, judging from the DenTron example, they are investing in businesses these days, not just in their own growth. I was assured by the president of DenTron that the Scientologist who had worked with them had recently left and that there was no more connection.

Getting back to Dianetics. . . I've kept in touch with most of the better known psychotherapies over the last thirty years and I know of none which works with the ease, speed, and thoroughness of Dianetics. I got to be quite good with the techniques involved and found that I was able to discover the roots of most problems people were having and could help them substantially in a matter of hours. But I also found that very few people really want to be helped. They've adjusted to some degree to their mental problems and are defensive about them.

Many of the basics of Dianetics were pooh-poohed by the establishment back in 1950, so it has been interesting for me to keep abreast of the development of these other schools of therapy and see them gradually accepting the very concepts which they found so totally ridiculous in 1950.

One of the basic concepts had to do with the way the brain ties up part of its ability to think when faced with a painful situation, either physical or mental. The most fundamental rule for any organism is to survive and thus pain signals are interpreted as a threat to survival. By deconditioning these painful moments in the past, we found that IQs increased and the ability to think zoomed upward.

Fortunately for our peace of mind, all of these pain memories and the subconscious responses they force upon us are carefully hidden from our conscious mind, with behavior, no matter how weird, rationalized.

Well, sorry for the usual digression, but I don't think I've ever written about Scientology or Dianetics before, and I suspect that very few people alive know about the possibly true roots of this amazing psychotherapy. And, yes, I'm familiar with Freudian analysis, the Karen Horney school, Gestalt psychology, Korzybsky, Examiner Therapy, Integration Therapy, and so on.

Did Hubbard come across the manuscript for Dianetics in a hospital in Burma during the war and pick it up from the dying real author? If Hubbard is dead, we may never know. But we do know that he was able to use that start to build a multi-billion dollar empire reaching around the globe.

HAM HELP

I am looking for the schematic and instruction manual for the Hewlett Packard 170A oscilloscope. I will pay all costs.

John Goodyear W6HVB
2985 Saratoga St.
Riverside CA 92503

I need the manual for the Knight G-30 grid-dip meter. I will pay reproduction and postage costs.

J. E. Smith K5PTC
2504 Conflans
Irving TX 75061

I would like to use my Atari 800 computer for RTTY, both Baudot and ASCII. Can anyone help me find information and hardware?

Ron Griesback WD9HDO
1712 N. Harriman
Appleton WI 54911

I am looking for schematics and operating manuals for the following equipment: a US Navy 4.0-27.0-MHz RBC-1 receiver; a Lakeshore Industries "Band Hopper" SSB vfo; and a Central Electronics model 20-A multi-phase exciter. I will pay for manuals or copying costs.

Peter Doherty W1VO/7
PO Box 291
Port Townsend WA 98368

My flea-market Eldice transmitter, model SSB 100ML, manufactured by Eldice Electronics of Mineola NY, did not come with a manual or circuit diagrams. I would like to buy a manual from someone who has a spare set or borrow some that I could copy.

Richard E. Downing W1TXS
16 Woodside Terrace
Springfield MA 01108

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego. 827-5732 (Reno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

Sacramento CA

TOWERS—galvanized steel stack/crankup and accessories. Northern California factory direct to you. **California Antenna Systems, 6020 Windy Ridge Road, Shingle Springs CA 95682, 677-9540.**

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Azden, AEA, Kantronics, Santec. Full Line of Accessories. No Sales Tax in Delaware. One mile off I-95. **Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.**

Preston ID

Ross WB7BYZ has the Largest Stock of Amateur Gear in the Intermountain West and the Best Prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

Bloomington IL

ROHN TOWERS—Wholesale direct to users. All products available. Write or call for price list. Also we are wholesale distributors for Antenna Specialists, Regency, and Hy-Gain. **Hill Radio, 2503 G.E. Road Box 1405, Bloomington IL 61701-0887, 663-2141**

Terre Haute IN

Your ham headquarters located in the heart of the midwest. **Hoosier Electronics, Inc., #9 Meadows Center, P.O. Box 3300, Terre Haute IN 47803, 238-1456.**

Western KY

Sell new and used equipment & service. **L&S Radio, 307 McLean Ave., Hopkinsville KY 42240, 885-8071.**

Littleton MA

The Reliable Ham Store Serving N.E. Full line of ICOM & Kenwood. Yaesu HTs, Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delta protectors, ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. **TEL-COM Electronic Communications, 675 Great Rd. (Rt. 119), Littleton MA 01460, 486-3400/3040.**

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, DenTron and many more. Open Monday through Saturday, 0830 to 1730. WB8VGR, WB8UXO, WD8OKN and W8RP behind the counter. **Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor MI 48104, 668-8696.**

Somerset NJ

New Jersey's only factory-authorized ICOM and Yaesu distributor. Large inventory of new and used specials. Most major brands in stock. Complete service and facilities. **Radios Unlimited, 1760 Easton Avenue, P.O. Box 347, Somerset NJ 08873, 469-4599.**

Buffalo NY
WESTERN NEW YORK

Niagara Frontier's only full stocking Amateur dealer. Also Shortwave, CB, Scanners, Marine, Commercial. Operating displays featuring Kenwood and others. Towers, Antennas, Sales and Service. **DX Communications, 3214 Transit Road, West Seneca NY, 668-8873.**

Amsterdam NY
UPSTATE NEW YORK

Kenwood, ICOM, Drake, plus many other lines, Amateur Dealer for over 35 years. **Adirondack Radio Supply, Inc., 185 West Main Street, Amsterdam NY 12010, 842-8350.**

Syracuse-Rome-Utica NY

Featuring: Kenwood, Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy-Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. **Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 736-0184.**

Columbus OH

The biggest and best Ham Store in the midwest featuring quality Kenwood products with working displays. We sell only the best. Authorized Kenwood Service. **Universal Amateur Radio Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

Scranton PA

ICOM, Bird, Cushcraft, Beckman, Fluke, Larsen, Hustler, Antenna Specialists, Astron, Avanti, Belden, W2AU/W2VS, AEA, Vibroplex, Ham-Key, Amphenol, Sony, B&W, Coax-Seal, Cover Craft, J.W. Miller/Daiwa, ARRL, Ameco, Shure. **LaRue Electronics, 1112 Grandview St., Scranton PA 18509, 343-2124.**

Mountaintop PA
WILKES-BARRE AREA

VHF/UHF Equipment & Supplies—From HTs to kW Amplifiers, Transverters, Connectors, VHF/UHF/Microwave Linear Amplifiers, GaAsFET Preamps, OSCAR Equipment, Low Noise Preamps, Antennas, Power Supplies. From: Lunar, Microwave Modules, UHF Units/Parabolic, ARCOS, Astron, F9FT-Tonna, Tama, DenTron, KLM, Mirage, Santec, Tokyo Hy-Power, Amphenol. Two Stamps for catalog. **The VHF SHOP, Dept. S, RD 4, Box 349, Mountaintop PA 18707, 868-6565.**

Dallas TX

IBM PC/Apple aftermarket products; hobbyists' electronics project kits: $50.00 complete modem kit, subscription/satellite TV decoder kits, EPROM programmer/duplicator, popular memory IC testers, data sheets, application notes, and more than 6000 parts in stock. Semiconductors, discretes, video products, tools. Please write for your free literature/catalog. **Independent Electronics, 6415-06 Airline Rd., Dallas TX 75205.**

Baltimore/Washington

Avantek transistors, amplifiers, oscillators and LNAs. Coaxial cable and connectors. Blonder Tongue dealer with Microwave laboratory. **Applied Specialties, Inc., 10101G Bacon Drive, Beltsville, Maryland 20705. Wash. 595-5393, Balt. 792-2211. 7:30 a.m. to 6:00 p.m. Monday thru Friday.**

STILL ANOTHER FCC REVOLUTION

The FCC is still pursuing deregulation with a passion and, for the most part, I'm in tune with this. I think amateur radio would be much more able to provide the services it is supposed to if we had far fewer limitations. Well, they just may be in the works, according to some information sent in by watchful K1NEB.

Docket 83-114, "A Re-Examination of Technical Regulation," has the intention of eliminating burdensome technical regulations for all Services, and that obviously includes Amateur. If you think about this for a bit, you'll see that this could be the weight lifted off our shoulders that we have been needing for years.

Within the purview of this docket, we could find the limitations on RTTY speeds, frequency shift, and so on eliminated. We've never needed these. We've been perfectly able to test out our own technical parameters and set our own standards without the help of the FCC, with their usual limitations which have been brought forward from years ago.

If we can get rid of these bothersome remnants of the past, we can experiment with more efficient data communications and error-correcting codes without always having to fight for Special Temporary Authority releases. The pressures of the marketplace will encourage the development of standards, but the freedom from oppressive regulations will allow us to try different ideas and keep finding better ways of communicating.

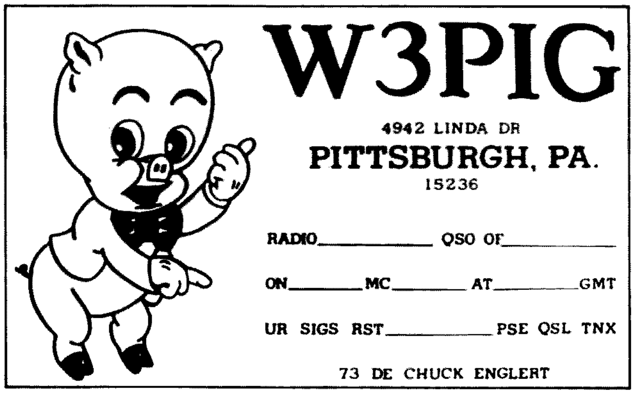
We're going into a digital world—digital messages, digital pictures, digital voice, digital music. If we don't keep up with all of this, we are going to find ourselves redundant. Will we still find pileups of analog voice DXers trying to get through to DXpeditions in twenty years? Or will we be sending bursts of digitalized voice at high speeds which will be received by a holographic-coherence detector and queued up for response?

The Honor Roll contingent may want to fight it to the death, but all those jokes about automatic DXCC rigs are getting believable. As soon as someone comes up with a good automatic-identifying system for rigs, we are well along that road. Once it's possible to have your rig work and confirm 300 countries in a day all by itself, we may be waking to a time when amateurs in rare countries will actually be able to have interesting contacts instead of being hounded off the air every time they show up.

The dropping of technical restrictions could help the development of facsimile and slow-scan television, allow more realistic power limitations for some repeaters, allow FM stations to add more services (such as teletext, communications, and calling), and might let amateurs experiment with wider band systems which transmit shorter times to make up for the use of frequencies. After all, our limitation is a combination of frequencies and time and it is getting time to think about this.

You know, just as the video

Continued on page 102



QSL OF THE MONTH

To most hams, a callsign is as important as a name. Countless hours have been spent devising memorable phonetics for calls or selecting the absolute best phonetics for a specific purpose—those with the most audio punch for ramming through the DX pileups or those with the shortest number of syllables for rapid contest calls. But there are hams among us who have the good fortune of a callsign instantly recognizable. Such is the case with this month's QSL of the Month winner, Chuck Englert W3PIG. Although the suffix to Chuck's call is none too complimentary, he has turned it into an interesting and memorable QSL card. With this familiar face looking out at you from the wall of the shack, you might forget the QSO, but you will never forget the call.

To enter *73*'s QSL of the Month contest, put your card in an envelope with your choice of a book from *73*'s Radio Bookshop and send it to *73*, 80 Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries not mailed in an envelope or which do not specify a book will not be accepted.

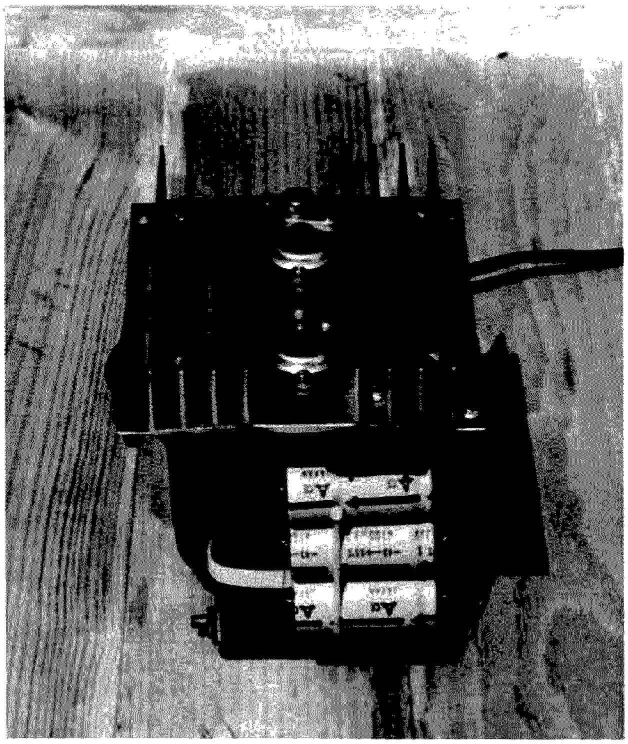
Construct This Customized Power Supply

Whether you want 5 Amps or 30, this supply can give it to you. But you only pay for what you need.

With more and more equipment on the market requiring a separate source of 12 V dc, almost every ham shack needs a power supply capable of operating such equipment on 115 V ac. Even if your 12-volt transceiver is normally mobile, you might want to bring it into the house for testing or as a substitute for the base station. Many HF transceivers operate at a high power level requiring 20 to 30 Amps on transmit while QRP rigs and VHF transceivers require 5 to 10 Amps or less. This article describes a general power supply design which can be expanded in 5-Amp steps from 5 to 30 Amps. That way you do not need to build a larger unit than your requirements dictate.



The completed 10-Amp unit.

This power supply is unique in both its simplicity and its immunity to damage from overloads. The heart of the circuit is an LM340T-15 integrated circuit, a fixed 15-V regulator with short-circuit and high temperature protection. It provides excellent regulation and is virtually immune to overload and short-circuit damage. The output of this regulator IC is fed to a Darlington-connected emitter-follower which increases the rated 1.5-Amp output of the IC to as high as 30 Amps. A single driver transistor, Q1, is used with from one to six output transistors, Q2-Q7, connected in parallel depending on the output current required. One 2N3055 power transistor is used for each 5 Amps of output. The 0.15-Ohm resistor in the emitter of each transistor performs a dual function. It serves as a current-sense resistor providing a voltage output proportional to the current through its transistor and provides for equal sharing of current among the parallel-connected transistors.

The LM340 is so well-protected from overload that it can operate into a short circuit all day. If the chip temperature becomes too high, the internal thermal protection will simply shut it down until the heat sink cools off. The external current-amplifying transistors need some protection, though, since their power dissipation could far exceed their ratings in the case of a short

Supply Capacity	C1	F1	T1
5 Amps	7,500 uF, 25 V	2A SB*	Triad F-242u
10 Amps	15,000 uF, 25 V	4A SB	Triad F-243u
15 Amps	22,000 uF, 25 V	6A SB	Triad F-244u
20 Amps	30,000 uF, 25 V	8A SB	Triad F-244u
25 Amps	40,000 uF, 25 V	10A SB	Triad F-245u
30 Amps	50,000 uF, 25 V	12A SB	Triad F-245u**

*Slow-blow fuse.
**CW & SSB service only.

Table 1.

circuit or sustained overload. To accomplish this protection, the voltage across one of the emitter resistors is fed to the gate of SCR1. A current of 5 Amps develops 0.75 V across the 0.15-Ohm resistor, which is sufficient to trigger the SCR. As soon as SCR1 has fired, the pass stage of the regulator is shut down completely and the output of the LM340 is connected directly to the load. The IC regulator then supplies its short-circuit current (about 1.5 Amps) to the load through the SCR. This current holds the SCR on until the power supply is shut off and allowed to reset itself automatically. The function is essentially that of an electronic circuit breaker.

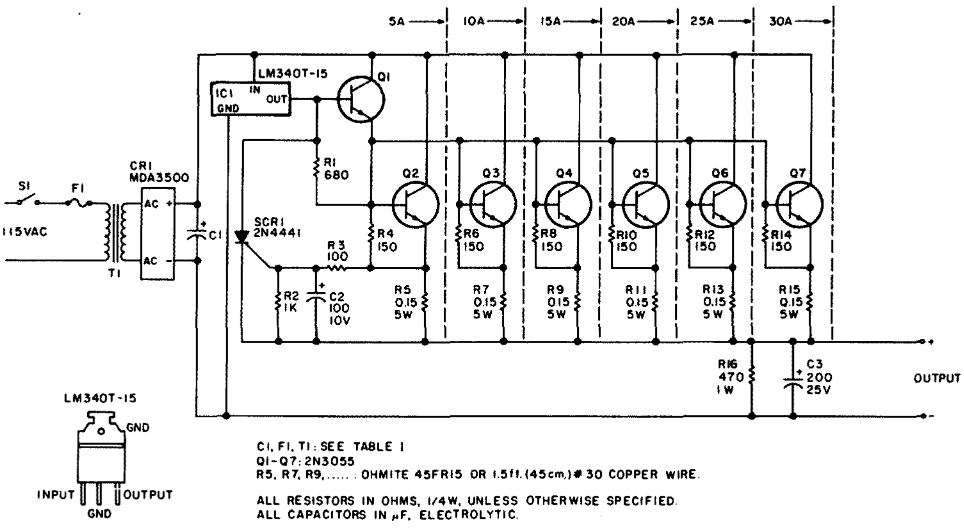


Fig. 1. 13-V-dc power supply schematic.

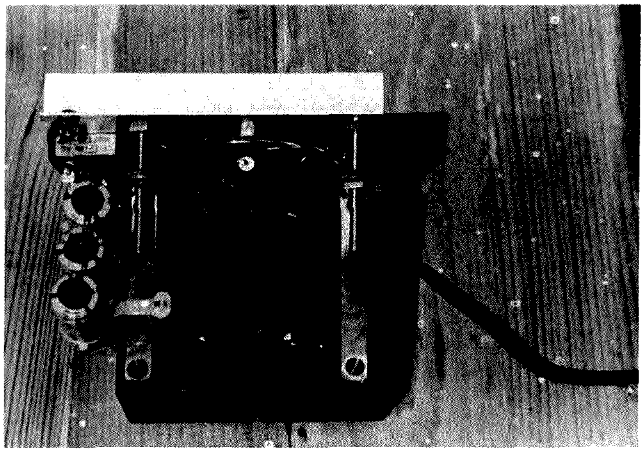
Another advantage of using the LM340 is thermal protection. If the IC is mounted on the heat sink near the output transistors, the internal temperature-sensing circuitry will detect the sink temperature and shut the whole supply down if it becomes excessive.

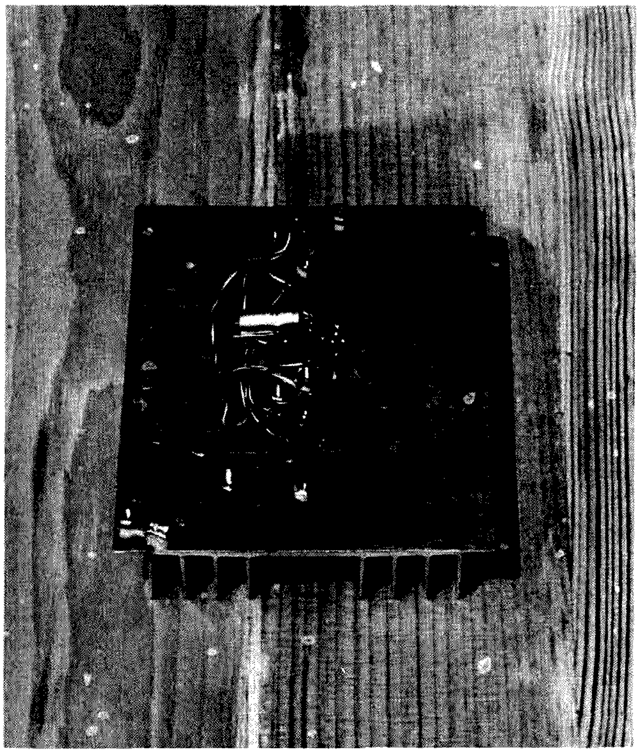
The output of the supply is equal to the output of the IC regulator (15 V) minus the base-emitter drops of the driver and pass transistors and the voltage across the emitter resistor. Since this voltage varies with current, the output voltage will change from 14 V at no load to about 13 V at full load. This is much tighter regulation than an automotive electrical system where variations of 11 to 16 V are possible. All amateur equipment which requires a nominal 12 V is designed to operate over this range with 13 to 14 V being optimum. Line regulation is essentially perfect with no variation in output seen for varying ac line voltages.

Construction can be as simple or elaborate as the builder desires. The photos show that the whole circuit can easily be built right on the heat sink. In the author's 10-Amp version, the heat sink was mounted on the transformer with 3/16" bolts, creating a compact and sturdy open-frame design. The 115-V-ac connections were heavily insulated with plastic rubber for safety. If your supply can be tucked away out of sight, this is an ideal (cheap) construction method. If appearance is important, the supply could be built into an attractive box, into the speaker cabinet in the station, etc. The heat sink(s) must be mounted external to an enclosed cabinet so that adequate cooling can take place.

Table 1 lists suggested components for various power levels of the supply. The transformer, T1, must be chosen to supply about 18 to 20 V to the filter capacitor, C1, at the full load. The LM340T-15 requires a minimum of 17 V to oper-



The heat sink can simply be bolted to the transformer to make a compact open-frame supply.



All of the circuitry fits neatly on the heat sink.

ate. The higher the unregulated voltage, the greater the power dissipation will be in the power transistors. To keep heat-sink requirements within reason, a voltage higher than the low 20s should not be used. In the parts list, Triad F-240 series transformers are suggested. These have two secondary windings which should be connected in parallel. Try salvaging a battery-charger transformer; the voltage should be about right. If only SSB and CW operation are contemplated, then some skimping can be done on the transformer and heat sink. However, continuous operation such as FM, RTTY, or SSTV requires a transformer whose amperage rating equals the full output of the supply, and heat-sinking of 2° C/Watt per transistor or better. One Wakefield 401 or equivalent for each transistor should be adequate. Be sure to mount the fins vertically and in a location where free air circulation is provided. Fan cooling will greatly reduce the heat-sink size required. The fan should be controlled by a thermostatic switch (70° C would be a good temperature rating) mounted near the hottest part of the sink.

Many power supplies are available to operate 12-V-dc ham rigs, many of which are very expensive. With the exception of the transformer, all the components specified in this circuit are quite economical. A little scrounging and ingenuity will result in a power supply of exceptional performance and reliability for a very low cost. ■

All parts, including a 30-Amp transformer, are available from All Electronics Corp., PO Box 20406, Los Angeles CA 90006. Send for a catalog.

VisiCode: The VIC 20 Way to Extra Class

First you get random practice groups. Then you get the answers.

Photos by KA7AQA

Well, it finally happened. After a concentrated, purposeful effort for several years to ignore computers, I succumbed as I knew I eventually would. To justify the expenditure, I decided to get a computer that could be used for games and have both sound and color so as to interest my 8-year-old son, Tom. And, of course, it had to be relatively inexpensive. I chose the Commodore VIC 20.

Program listing.

In recent months, this computer has become very popular, especially among the local hams. I decided it would be fun to incorporate some ham uses for the VIC 20, and as a first attempt, recalling having read an article in *73* about a Morse-code learning program for the Commodore Pet, I thought a similar program would be appropriate. Looking back through my library of *73*s, I retrieved the article, "The Code Pet," by Alden Lansdowne AA∅G, December, 1981.

Using Alden's program as a guide, I began converting (in computerese, "transporting") the Pet code program into a format that the VIC 20 would like. I can tell you that there is no better way of learning how your computer works than to get into programming, and transporting a program is perhaps a little less traumatic than starting from scratch.

After many hours of hair-pulling and mumbling unkind words, I finally got a usable program going. I still had some timing problems with the code speed, and I enlisted the aid of Hoa Nguyen KA7AQA, who is one of our local VIC 20 experts. He quickly solved the problem. The finished program is one that will make it easy for anyone with a VIC 20 not only to learn Morse code, but also to be able to increase code speed up to 20 wpm.

The program features a choice of code speeds of 5 to 20 wpm and also a choice of having the characters displayed directly after being sent (good for learning at the slower speeds) or keeping the screen blank until 41 groups of random characters have been sent—then automatically displaying them so that you can check your accuracy. You also can stop the program for an immediate display by pressing the S key.

Code groups traditionally have consisted of five characters, but due to the VIC 20 displaying 22 characters per line, I decided that three groups of six would avoid split groups on the screen. I stopped at 41 groups to avoid scrolling.

The listing should be self-explanatory to an experienced programmer. However, here are a few remarks as to what is taking place within the program that may be of help to a beginner.

Lines 260–270 contain the formula for selecting the code speed.

- P controls the character speed.
- K controls the space between characters.
- P and K together control the pause between character groups.

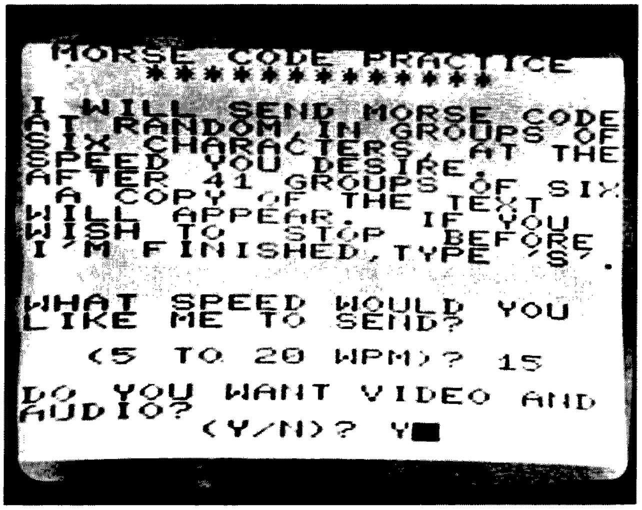

Photo A. Screen display after loading program and selecting code speed and audio plus video.

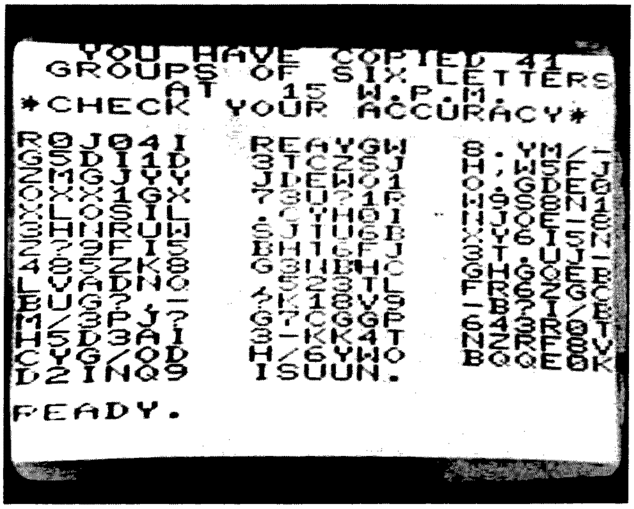

Photo B. Screen display after 41 groups of characters are shown (full screen).

It was found that a formula involving 1/P gives more accurate code speed than the linear equation AA0G used.

● Line 340 generates a character.

● Line 350 selects only the ASCII characters of the alphabet, numbers 0 to 9, plus certain punctuation marks.

● Line 490 puts the character on the screen. If you wish to see each character before the code is sent, change this line number to 355.

This has been a very interesting learning experience and I know you will enjoy using the program. It should be very useful in radio clubs for group code practice as well as individual use.

Feel free to customize it in any way you like. I am convinced that computers are compatible with ham radio and are here to stay.

For any of you who would like a taped copy of this program, send me a blank cassette tape along with $3.00 for postage and handling, and I will make you a copy. ■

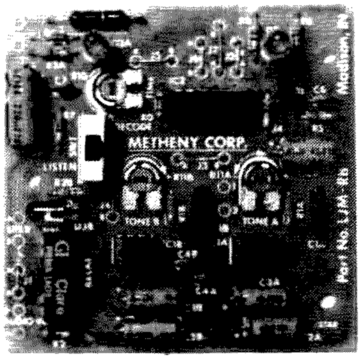
$15 DTMF DECODER $15

The LJM2RK decoder kit converts your receiver into a special receiver or control. When a user-selected time-tone combination is received, the output provides a relay control for activating speakers or other devices.

INPUT: Audio from transceiver, scanner, etc.
OUTPUT: SPST (N.O.) relay.

FEATURES: Single or dual tones adjustable over the 16 digit Touch Tone range • Adjustable response time • Relay output • Manual or auto reset • Single tone ON latching with different single tone reset OFF • Operates on 12VDC • Interfacing of multiple boards for multi-digit sequential activation and reset.

APPLICATIONS: Call-up system • Repeater or commercial controls • Etc. limited only to your imagination •



Actual Size 3"x3" - Shown Assembled

LJM2RK decoder kit includes all component, relay, and P.C. Board. . . . $15 plus $1.50 shipping.

LJM2RC enclosure kit includes molded case, speaker, input cable. . . .$5 plus $1.50 shipping.

Running Scared at Spratly

Only steel nerves and luck stood between the 1979 DXpedition and disaster.

Ed. Note: In late April, a yacht carrying four German hams on a DXpedition to the Spratly Island area was fired on by Vietnamese forces. Deithelm Mueller DJ4EI and Gero Band DJ3NG perished following that attack, which occurred about 350 miles south of Vietnam in an area claimed by both Vietnam and China. The rest of the party was later rescued by a freighter.

The following is from the log of the sailing yacht *Banyandah*, South China Sea, Saturday, March 31, 1979.

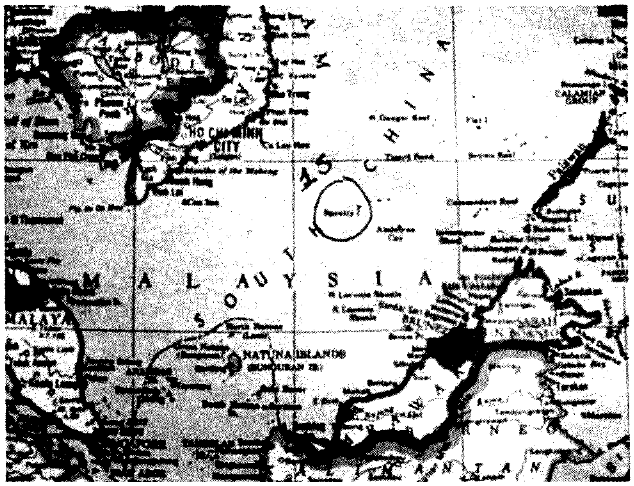
0600:
Dawn is breaking on this, our third day at sea since departing Brunei, North Borneo. On the far western horizon, an expanding band of changing pastels is rising. The sea and sky are becoming distinct.

The sky brightens further, highlighting the pearl-grey clouds with crowns of liquid gold, and a charge of excitement runs through all on board. Silhouetted against this display of nature's beauty, my six passengers are scanning the horizon for the first hint of our mysterious destination. Their chatter sounds like a flock of birds greeting a new and lovely day.

Ahead, somewhere, lies Amboyna Cay of the Spratly Islands. According to the pilot book, we should find only a 50-yard circle of sand surrounded by a bit of fringing reef. But recent hostile military activity in this area may have changed all of that.

0700:
According to my calculations, we should be very close. I shall climb to the masthead lookout for a look around.

0715:
A tiny irregularity breaks the otherwise barren horizon, and pointing to it I yell



Map of the South China Sea area, with the Spratly Islands circled.

Amboyna Cay, showing the military camp.

Victory! Wharfside Brunei, after 1S1DX

The sailing yacht Banyandah.

down, "Land, ho!" A cheer rises up from the deck, and happy, excited faces turn to follow the direction of my outstretched arm.

Since nothing can be seen from deck level, a barrage of questions assaults me as I climb down the 50-foot mast. "How big is it?" "Is it sand?" "Any trees?" "Did you see any buildings?"

"Hold on, you guys. It was just a tiny blip. In a half-hour it will pop up out of the ocean as if by magic."

0745:
Through binoculars, a crescent of yellowish sand is just visible, rising out of the sea as we ride up the swell, disappearing as we slide down. Everybody wants a look through the glasses, but Harry Mead VK2BJL, the team leader, gets the first chance.

"Jack, is that a rock I see on the right-hand side?" We rise up on a large swell and I see what could be a rock, a wreck, or almost anything. It's just too small to make out.

0800:
It's not a rock or a wreck. It now looks like a huge tent—like a circus tent, only tan in color. Other objects, possibly structures, are situated about it. I'm beginning to get worried. Who could be on our island? The guys are getting edgy also; Stew K4SMX keeps talking about a letter he has which explains that we are a scientific expedition studying radio propagation. He keeps saying that the letter is written in both Russian and Vietnamese. That sounds as if he knows something I do not.

0810:
People are visible on the island. Three distinct groups are equally distributed around that tiny mound of sand, with a smaller group at the top. The "top" is only eight feet above sea level.

0815:
The smaller, centralized group has begun signaling us with semaphore flags. Everyone turns to me, and John KV4KV asks the obvious: "What are they saying?"

"Look, I haven't a clue. But I think I'll anchor the boat just offshore and row in for a friendly chat. After all, we don't even know who they are. Besides, they can only tell us to go away, right?"

My wife doesn't look so sure, but the rest of the group nod or mumble comments like, "We've come this far; we ought to give it a go."

After everyone agrees, Stew beams his gracious southern hospitality smile and says, "I'll even go in with you."

Trouble

0915:
We're running scared, powering away from Amboyna Cay just as fast as our eighty-horsepower engine will push us. And we're searching the horizon in every direction for any intruder, deathly frightened that we might sight one.

What happened back there was insane. I mean, we're just ordinary folk—peaceful family men—out on an adventure. We meant them no harm, and there was definitely no reason for them to try to kill us.

I guess things really began to happen once we came within a mile of the island. From that distance, we could see that the cay was about half the size of a football field and that at the center were several buildings of clapboard and corrugated iron, as well as two radio towers. We also could see that the perimeter was reinforced with a wall of sandbags and that on this wall was a sign which read in large white letters, "BAOTHEP."

I began my final approach with one operator at the radio, scanning the bands, listening for a possible contact with the island. The other operators were on deck, clustered close together by the center cockpit. Judith was at the controls, and I was at the bow, searching for a clear patch in which to anchor.

I remember that it had become deathly quiet—I heard only the distant sounds of a light wind upon the sea and the sound of my heart beating in my ears as it pumped adrenaline through my body. Then, as I

reached out for the anchor-release mechanism, an abrupt order rang out, and groups of green-clad men began to scatter.

Explosions cut the air—boom . . . boom . . . boom. The physical impact of the concussions slammed into my body, and I was involuntarily flung to the deck, my mind already beginning to record every intimate detail of those hour-long seconds.

I saw four puffs of grey-white smoke hanging in mid-air above the cay. I heard a shrill whistle and felt heat on my cheek. I saw the five operators throw themselves headlong into the cockpit, heedless of any injury. As I looked along the deck, I saw the two drums of gasoline nakedly lashed to the rail. For an instant, my mind's eye imagined a huge blossoming orange-red ball of death erupting from them. Then I screamed, "Move it! Move it! Full power!"

Getting myself up on all fours, I saw Judith at the helm, kicking bodies away from the controls. And then, with her eyes sunk deep in their sockets and her teeth exposed in a grin of animal fear, I watched her slam the boat into gear and push the throttle to full power.

For what seemed like hours, we waited, rigid and unmoving, our every nerve straining, searching for the slightest warning of a new attack. But none came. We were lucky.

Success At Last

1S1DX, Spratly Islands 1979, is now history. Directly after the attack, we returned to Brunei. Three expedition members thought it too dangerous to continue; secretly, so did I. But Harry, Stew, and Bill K1MM wanted to try again. A new island was chosen, one which US government officials assured us was "safe." That assurance reinstated my confidence, and I accepted the charter. Later, those assurances proved nothing more than hogwash.

We docked at Maura port in the early morning hours of the 3rd. We reprovisioned that day and departed that night. Two and a half days later, on a morning very similar to the one at Amboyna, we made landfall. Immediately, two unmarked ships closed in on us from opposite directions. One steamed directly across our bow, only 200 yards off. It appeared to be a phantom ship—no flag, no markings, and no crew visible. When it had passed, we altered our course, put on the power, and prayed.

Again, we were lucky. But all of us thought we had just about used up our quota of luck. We were tired and fed up with feeling scared all the time. We decided to head for home.

I set a course for a reef which was charted as completely submerged, but which was near our rhumb line and worth investigating. We arrived the next morning, a glassy smooth day with absolutely no swell or wind.

As we circled the reef, I watched from the masthead, shaking my head in disbelief as we rounded the weather end. Our luck was still holding, for right on the edge a cluster of coral rocks had been dashed up by some long-ago storm and a baby sand island was forming. It was no larger than my deck area, but it was above water at all tides.

This tiny scrap of sand, surrounded by miles of open ocean and hostile forces, became 1S1DX, the last active amateur radio station in the Spratly Islands. ■

The COR of a Reliable Repeater

Carrier-operated relays are the most-used circuits in any repeater. Use this simple design to get maintenance-free operation.

Frank Kalmus WA7SPR
RF Power Labs, Inc.
21820—87th S.E.
Maltby Industrial Village
Woodinville WA 98072

There are a great number of repeaters on the air at the present time, and nearly all of them require the use of a reliable Carrier Operated Relay (COR).

The COR is the gadget that switches on the repeater transmitter when the receiver detects an incoming signal. It is automatic and uses a relay to switch around some of the circuitry in your repeater, making possible remote control of the repeater without station operator attendance.

An average repeater will trigger about 25,000 to 100,000 times per year. This requires a COR with very reliable components to ensure continuous operation over many years. This particular relay, COR-1, is very simple in construction and throughout its design uses quality parts readily available at reasonable prices.

The COR-1 is constructed on a standard plug-in PC card. Messing around with ICs and timers on top of a remote mountain can be a frustrating experience, and it was to make replacement easy (should it ever be necessary) that I designed the COR-1 on a plug-in card, as well as the matching access-code and tone-decoder boards. The following circuit has been on the air in my 220-MHz repeater for over five years now and has never given me any problems.

Description

The COR is a control module designed for repeater use. In the presence of a carrier, the repeater receiver will activate the COR causing the relay to energize and triggering a 3-minute timer. After this time has elapsed, if the received carrier has been continuously present, the COR circuit will open the relay and the repeater will "time out" until the signal breaks for at least 200 ms. A delay that can be set from .1 to 4 seconds will hold the relay in operation whenever the carrier shuts down ("squelch-tail timer").

The ID input does the following: (a) switches the relay on when activated, (b) allows for normal COR input

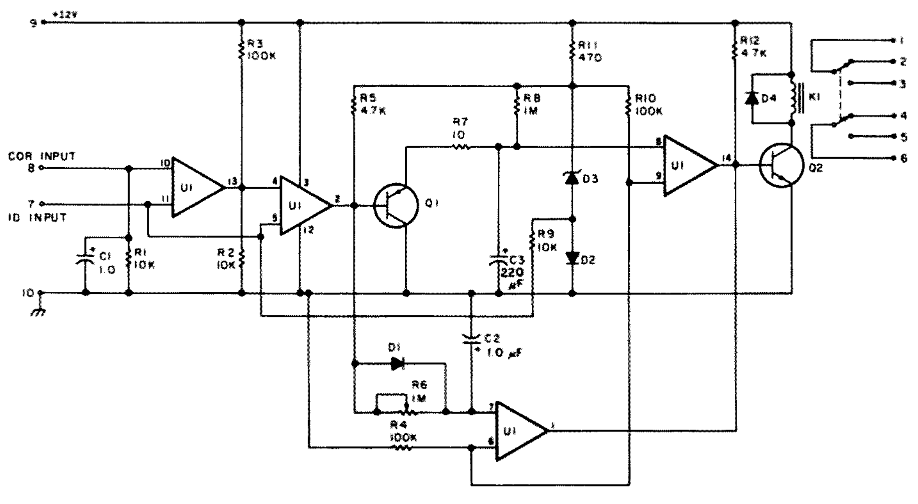

Fig. 1. Schematic of the COR-1.

operation when opened, and (c) disables the circuit when shorted to ground.

Theory of Operation

With the ID input open, a positive voltage greater than .8 volts applied to the COR input will change the status of the comparator's outputs 2 and 13. Transistor Q1 opens and C3 starts charging through R8 for the 3-minute timing. Comparator output pin 1 will drive Q2 and the relay. Each time the COR input goes below .6 volts Q1 will turn on, discharging C3 and resetting the 3-minute timer; also, C2 will discharge through R6, holding the relay in operation.

The ID input has been designed to be driven by any voltage above 1.2 volts, and when in the standby position should be left open. An internal bias circuit (D2, R3) fixes the potential at pins 5 and 11 close to .75 volts. An open collector PNP transistor is the appropriate way to attack the ID input. Any logic or analog input will do if an isolating diode is inserted in series (cathode to ID input). If shorted to ground, the ID input will disable the circuit.

For proper circuit operation, the inputs should not be driven above the power supply level; they can withstand up to 30 volts without any damage. Negative voltages at the inputs must be avoided if greater than 300 mV below ground level.

R1 and C1 are assigned to establish the input impedance and filter squelch pulses coming from the repeater. Their values can be adapted to other requirements. The circuit will operate from 9 to 16 volts.

Testing

Apply 12 volts to the COR. With all inputs open the output relay will be off. Using a jumper, put 12 volts in the COR input. The relay will operate immediately. By taking the 12 volts out, the relay will hold for a few moments before it goes off (set this time by rotating R6).

To check the main timer, hold a 10k-Ohm resistor in parallel with R8 while activating the COR input with 12 volts. After a few seconds the relay will kick off. That means the timing circuit is operating normally.

Ground the ID input with a jumper. The relay will not operate whatever the COR input condition is. Remove the ground and apply 12 volts to the ID input. The relay will operate and the circuit will perform just as with the COR input.

I am sure that with one possible exception, the relay, you can find most parts for this project in your junk box. It should take only a few minutes to put the COR together once you have the PC board finished. A direct-contact PC print of the 1:1 positive takes only a few minutes to make. Good luck!

If you have any problems with the construction or parts availability, you can buy the entire COR-1 board, fully tested and assembled, from me for $23.00 postpaid. Please address me at 7016 NE 138th, Kirkland WA 98033. ■

Precision Speed Control for the Billboard Keyer

Get more for your money by adding this circuit to last month's project.

Sooner or later, every CW operator tries to determine just how fast he or she can send or receive Morse code. For those reaching for a higher class of license, the need to know is far more significant than somebody trying to win a lie-swapping contest at the local club meeting. Recent issues of various ham magazines have shown different approaches to solving the problem in a state-of-the-art manner.[1,2,3] My contribution in this direction (reference 1) generated a considerable amount of mail from readers interested in duplicating the device or adapting the idea to their own needs. As stated in that article, the design was interfaced with a home-brew keyboard keyer which resulted in a very accurate method of determining code speed.

A second-generation CMOS keyboard keyer I designed[4] did not lend itself well to an LED readout circuit due to the heavy current demands of TTL integrated circuits and the seven-segment displays. A low-current CMOS design with liquid crystal display was contemplated but discarded as too costly. Months of frustration ended when the diagram of a low-frequency synthesizer was discovered in the *CMOS Cookbook* by Don Lancaster. It featured a low-cost, integrated circuit phase-locked loop and appeared promising. A prototype was quickly constructed and proved to be ideal in this application.

That which follows is a description of the basic theory, construction, and operation of such a synthesizer and its application to my latest keyboard keyer.

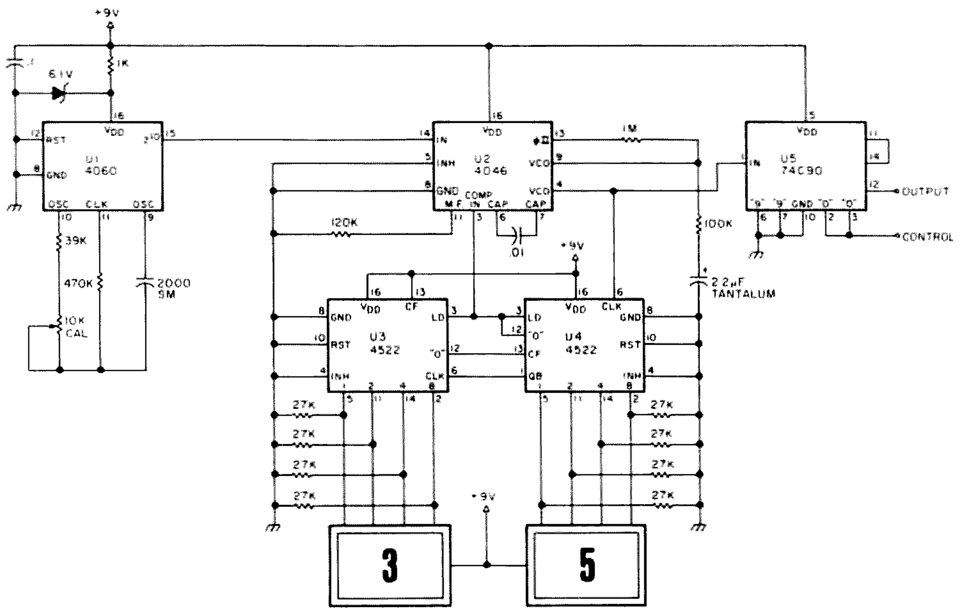

Fig. 1. Schematic diagram of the synthesized clock for the Billboard keyboard keyer.

What's Involved

Code speed in an electronic keyboard keyer such as the "Billboard" can be determined from the following formula: clock speed (Hz) × 2.4 = speed (wpm). Solving for a code speed of one wpm gives us the figure of 0.41666 Hz. This frequency is the basis for all frequencies generated in the synthesized clock.

The actual theory of phase-locked loops and frequency synthesizers using these devices is well beyond the scope of this article. Numerous papers on the subject have been published and the reader is encouraged to consult one of these if he or she feels the need for additional background. An excellent source of information on a very basic level is, again, the *CMOS Cookbook*. In fact, the majority of the circuitry presented here came directly from that book.

The function of the PLL circuitry in the synthesized clock is to multiply the reference frequency by any number between one and

ninty-nine as dialed up by the thumbwheel switches. The end result is the proper frequency necessary to generate any code speed from one to ninty-nine wpm.

A brief look at the schematic clearly indicates the simplicity of the circuit. Integrated circuit U1 is a unique and very versatile chip. It consists of a fourteen-stage binary ripple counter in addition to a pair of uncommitted gates. This IC and its associated components form the timebase which generates the reference frequency. The resistors and silver mica capacitor connected to pins 9, 10, and 11 along with the two previously mentioned gates form a digital relaxation oscillator. The 10k-Ohm potentiometer is a miniature ten-turn device and is used to adjust the oscillator frequency to exactly 4,266.6 Hz. The oscillator frequency is fed internally to the counter stages of U1 and is available at pin fifteen divided by 1,024. The resultant frequency is a 4.1666 Hz square wave which is fed to the input of the phase-locked loop chip, U2. Sharp-eyed readers will note that the decimal point has been moved one place to the right, thus corresponding to a clock speed necessary to produce code at ten words per minute. This is the actual timebase used, but a later stage will divide the output by ten for reasons which will be explained shortly.

A 6.1-volt zener diode and 1,000-Ohm resistor provide the necessary voltage regulation for the timebase oscillator to ensure both long- and short-term frequency stability. Likewise, a silver mica capacitor is specified in the timing circuit.

Integrated circuits U2, U3, and U4 perform the function of multiplying the reference frequency by the numbers indicated on the thumbwheel switches. Thus, if these switches are set to 35 as shown on the schematic, the output frequency from the voltage controlled oscillator (pin 4 of U2) will be 4.1666 Hz × 35 = 145.831 Hz. Referring back to the formula for determining code speed, we find that 145.831 × 2.4 = 350 wpm. A little fast for most of us, perhaps, but remember, we are going to divide this by ten shortly, which gets us back to 35 wpm.

If all this seems a bit confusing, the reader is invited to plug in the numbers which correspond to other code speeds to gain familiarity with the arithmetic involved. Work the formulas backwards a time or two and everything will fall into place.

This brings us to integrated circuit U5, a CMOS version of the ever-popular 7490 decade counter. The chip actually consists of a divide-by-five and a divide-by-two counter which, when cascaded, gives us the desired divide-by-ten function. It may appear unusual that the reference frequency was purposely chosen to be ten times the desired output and then divided later. It all comes clear, however, when one considers the needs of the actual keyer.

The original clock circuit in the Billboard is keyed. That is, it is only running during character generation. This is typical of most keyers and keyboards. For reasons beyond the scope of this paper, the synthesized clock must run continuously. It would, of course, be a simple matter to gate the output of the synthesizer on and off, but this would lead to intolerable and unpredictable time delays between a key-pressed command and actual character generation. By presetting U5 to zero (bringing pins two and three high) and holding it there, the output (pin twelve) is inhibited even though a string of clock pulses is present at the input. However, when the zero-reset line is brought low, the output is no longer inhibited and a string of perfectly symmetrical square waves at one-tenth the input frequency is presented to the keyboard circuitry. The delay between a key-pressed command and character generation is now insignificant, even at low speeds. At speeds in excess of ten words per minute, it is virtually identical to the keyed clock.

Only two connections need be made to the actual keyboard circuitry itself. Pin twelve of the 74C90 is connected in place of pin four (Q2A on the keyboard schematic) and pins two and three, the control lines, are connected to pin eight of Q3A, the CD4013 dual-D flip-flop.

Power for the synthesizer is taken from the same supply used to activate the keyboard. Current drain is in the vicinity of one to two milliamperes.

Construction

Once again, perfboard and point-to-point wiring were used to construct the unit. Miniature flea clips provide a convenient means of neatly terminating the wires which go off the board.

After the circuit was operating properly and calibrated, I coated both sides of the board with clear acrylic spray to prevent movement of the wires and provide a degree of protection from dirt and moisture. The synthesizer board was mounted with aluminum spacers and 6-32 hardware.

Calibration

Setting the timebase oscillator to precisely 4,266.6 Hz is most easily accomplished with the aid of a frequency counter. Initially, I attempted to measure the oscillator frequency directly at pin nine of U1. I found that the introduction of the frequency counter and probe to this sensitive part of the circuit caused the frequency to be pulled considerably. Instead, the thumbwheel switches were set to ninety-six wpm and the ten-turn calibration potentiometer was adjusted to show a frequency of exactly 400 Hz at pin one of the 74C90. If the builder does not have access to a counter, some other method of adjustment will have to be devised. Perhaps comparison of the synthesized signal to an accurately calibrated audio oscillator could do the job.

The long-term stability of the timebase and resultant accuracy of the synthesizer is nothing short of amazing. A calibration check was made six months after the initial adjustment and no change was necessary. Frequent on-the-air comparisons with others using sophisticated, microprocessor-controlled keyboards with programmable speed controls confirm the accuracy of this system.

Considering the minimal investment in both parts and labor involved, there is no longer a valid reason to have to guess at your code speed. Although no specific information is available, this design should be easily adaptable to other keyboards and regular keyers. I would be interested in hearing from others who have built this device and will respond to those who include an SASE.■

PC Boards for Penny-Pinchers

Get picture-perfect circuit boards without buying a darkroom.

Some years ago, I rediscovered a technique for making printed circuit boards which was prevalent in the fledgling years of the industry. Called silk-screen printing, it is a very acceptable method of transferring a resist pattern to a clad board, is very inexpensive initially, will be successful even for a beginner, and, once mastered, will find many applications in the ham shack.

Briefly, the technique involves the pressing of ink through an open-weave fabric which has had portions of the weave rendered impervious to ink. It's as simple as it sounds!

Getting Started

As with anything, there is a modest cash outlay. However, this is tempered by the fact that at least 50% of your initial cost is non-recurring. Even the total cost, amortized over several projects, is much less than any other method.

Materials are readily available from local suppliers in almost any community and can be obtained in one Saturday morning.

From past experience, a 12″ × 12″ (inside opening) frame should be adequate to handle 90% of the boards you will want to make. We'll use that as a construction example. Of course, you can make larger frames by following these general instructions later.

Procuring the Materials

You may be able to find a lot of the materials for this project by scrounging around the house. Remember, nothing is very critical; your own wood, hinges, screws, and whatever probably will work. Assuming you find nothing at all, be prepared to spend about $25.00. Your first stop should be a lumber yard. Here is what you'll need from this source:

- 5 feet of 1″ × 1″ clear pine trim lumber. Almost anything will work here; the 1″ × 1″ is nominal anyway.
- 1 piece of ½″-thick "good one side" exterior-grade plywood about 18″ × 24″.
- 4 #6 × 2″ flathead wood screws.
- 4 small flat angles and screws.
- 2 small butt hinges, no wider than the pine trim lumber you bought.
- 1 small bottle of white glue.
- 1 small can of white shellac.
- 1 quart of benzene.
- 1 package of cheesecloth, preferably real cotton.
- 1 ½″ or ¾″ paint brush, throw-away type.

Now find any halfway good arts and crafts or artists' supply store. You'll need to purchase the following articles:

- ½ yard (about 18″ × 36″) of screen-printing silk. This is sufficient to make two 12″ × 12″ screens. The clerk may ask you what "mummy" silk you require. Explain that you'll be printing on metal. Ask for a fine or medium weave.
- 18″ × 36″ (a half sheet) of *water-soluble* printing film. You may have to buy a whole sheet—no problem if you store the balance carefully rolled in a cool dry place. Heat and moisture degrade the film in time.
- 1 squeegee, at least as long as the narrowest dimension of the pattern you wish to transfer. The author's squeegee is 7″ long

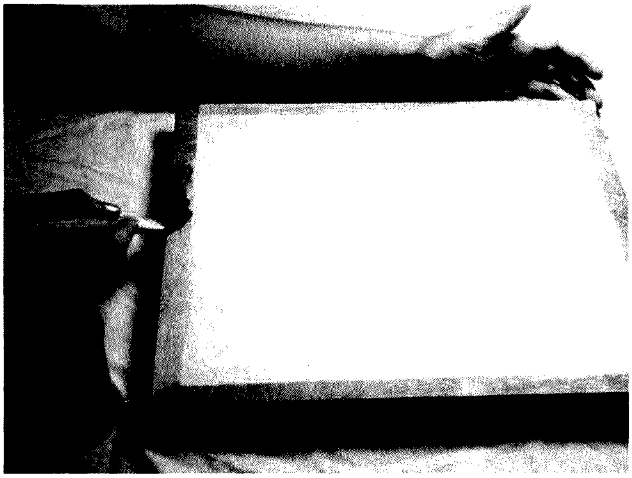

Photo A. Shellacking the screen to the frame.

Photo B. Newspaper/tape technique to block out open screen areas.

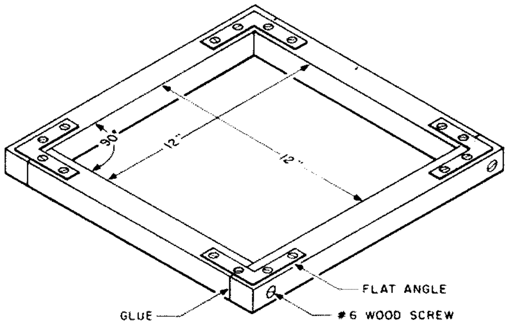

Fig. 1. Frame construction detail.

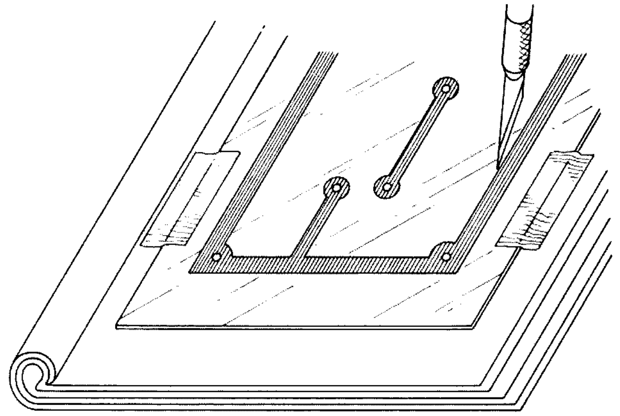

Fig. 2. Cutting out the circuit outline.

and suffices for 90% of the work done.

- 1 small can of screen-printing ink, any color that contrasts well with copper, suitable for printing on metal.
- 1 roll of 1"-wide drafting tape.
- 1 X-acto® knife and a package of #11 blades.

Make your last stop your neighborhood grocery. Purchase a bottle of *white* vinegar, a bottle of rubbing (isopropyl) alcohol, and a can of non-chlorinated scouring powder. You now own all the supplies you'll need to screen-print circuit patterns on copperclad.

Making the Frame

Sand the good surface and edges of the plywood to remove any slivers and give them a light coat of shellac. Clean your brush with a bit of the isopropyl alcohol.

Cut two pieces of wood 12" long, taking care to leave the ends as square as possible. If you have access to a miter box, it will simplify the task considerably. The squarer you build the frame, the more intricate the work you will be able to do with it.

Cut two pieces of wood 12" + twice the thickness of the wood you are using, again as square as possible.

Glue and screw the four pieces together as shown in Fig. 1. Predrilling the screw holes will help here. Try to make the joints as flush as possible. Wipe off excess glue with a damp sponge. Holding the frame square (against a square, how else?), assemble the four corner angles to it.

You should now have a neat, square frame measuring 12"×12" *inside*. Check the joints on the underside. They should be smooth. Any minor "step" should be sanded off. Shellac the frame with a thin even coat, and set aside to dry. Don't forget to clean the brush.

Preparing the Film

While you're waiting for the frame to dry, you can begin preparing the film from the artwork. Use drafting tape to secure your artwork to your work surface.

Cut a piece of film about 4" larger than the finished board size. Identify the emulsion side by gently scraping away at a tiny corner of the film with the X-acto knife. The green stuff that peels away is the emulsion. Tape the film, emulsion side up, over the artwork, centering it carefully.

Pay attention! This is the first area where you can seriously foul up and render your subsequent steps difficult and frustrating if not futile. You must now cut around the outline of the circuit pattern on the artwork (see Fig. 2). With the lightest touch possible, cut through the emulsion without creasing or badly scoring the mylar™ backing sheet. A little experimenting helps here. You'll soon develop a touch light enough to prevent scoring or creasing. Use a sharp blade and change often—usually at the first signs of snagging. If you crease or score the backing sheet, the film will curl up like a potato chip and render the subsequent steps very difficult or impossible.

Slip your X-acto blade carefully between the emulsion and backing sheet and lift off that emulsion representing the copper you want to stay behind (see Fig. 3). If you haven't quite cut through the emulsion, go back, cut loose the stubborn section, and continue peeling.

A couple of hints at this juncture: Use a thickness of wax paper under your palm to keep from sticking to the emulsion and transferring skin oils which will make the next steps harder. Use drafting tools such as straight edges, French curves, and circle and shape templates to guide the knife blade. This results in very neat work and allows you to hold some pretty amazing dimensional tolerances.

Another point: Unless you're making 1296-MHz striplines which require ultimate precision and strict adherence to the architecture, you can "square off" circuit pads and such in order to make life easier for yourself (see Fig. 4).

When you complete your film cutting, you should have a "negative" of your desired pattern. Untape it and turn it over. Rub your fingers lightly over the backing. You shouldn't be able to "read the pattern in braille." Don't score the backing sheet! Set the film aside between two sheets of wax paper and place it under a heavy book. This step is unnecessary if you are ready to adhere the film immediately.

Pick up the frame. It should be dry by now. A quick swipe with steel wool all over will smooth down the shellac and make the frame easier to clean later. Cut a piece of screen fabric four inches larger than the outside dimensions of the frame. Our design example requires a piece of fabric 18" × 18". See Fig. 5. Center the frame on the screen fabric. Fold a 1" hem on one edge as shown. Staple the hem against the side as shown. A stapler gun is nice for this. Keep your work neat. Repeat the same procedure on the *opposite* edge, pulling the fabric as taut as you can, anchoring the frame without damaging it.

Repeat the process on the other two edges, again pulling it taut on the last edge. You can do anything you want to tuck in the corners, as long as you don't turn them under the frame to create a lump on the screen side. The underside of the frame should be smooth.

If you're satisfied that the fabric is evenly and relatively taut on the bottom, you can now shrink the fabric. Gently, using running hot water, a generous sprinkling

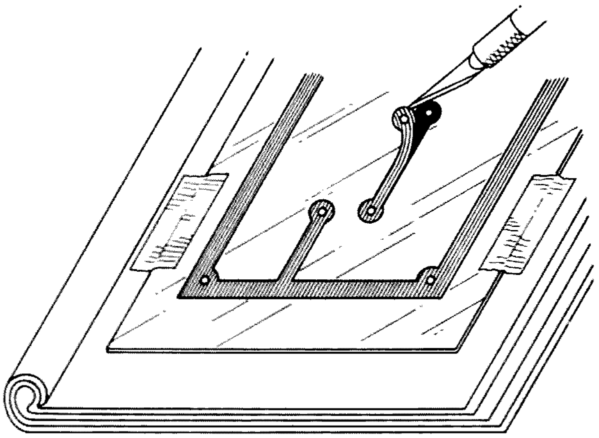

Fig. 3. Extracting the desired pattern.

of scouring powder, and your fingertips, scour the front and back of the fabric all over. Two or three scourings should do it. Rinse thoroughly with hot water. Inspect your work by holding it up to the light. Make sure that the weave is open and no areas are blocked by unremoved sizing or scouring powder. Once all traces of sizing and scouring powder have been removed, set the screen on edge to dry, turning it on a new edge frequently. Hot sunlight helps immensely to speed the process.

Meanwhile, procure four small pieces of copperclad board of the thickness you plan to use for your circuit board. Another hint: Cut your board with a pair of heavy tin shears, the kind sheet metal men call "bulldogs." It's much neater and easier than most home methods presently advocated.

Now examine your screen, making sure it's dry and quite taut. Thumping the screen with your finger should produce a satisfying "tunk" sound. As you can see, testing procedures are highly sophisticated. Once you are sure the screen and frame are absolutely dry, lay the screen bottom up on your bench. Carefully shellac the fabric which is in contact with the bottom of the frame (see Photo A). Do *not* shellac any other areas. Take extreme care not to dribble any shellac onto the screen except where it touches the wood. If you dribble shellac onto any other part of the screen, you will ruin it.

Place the now dry sheet of plywood, shellacked side up, on your table. Give the surface a quick swipe with fine steel wool. Center the screen frame, screen side down, on your piece of plywood. Slip a piece of the copperclad you prepared under each corner of the frame. Clamp the frame to the plywood taking care not to distort it (see Fig. 6). Neatly screw the two hinges to one side of the frame and to the plywood as shown.

You've just built a homebrewer's tool that will last you several years and, once you've been exposed to it, you'll wonder how you ever home-brewed without it.

You're already now to adhere the film to the silk. This is the second most vulnerable area, so extreme care must be taken. Swing your frame open and remove the copperclad shims. Place newspaper (enough sheets to equal or just exceed the thickness of the circuit-board stock you plan to use) onto the platen (plywood sheet). Make sure the frame closes flat without forcing it. Place your prepared film, emulsion side up, on the newspaper stack, centering it in the frame opening. Close the frame, ensuring that everything lies flat, more or less in contact with the silk. See why you weren't supposed to crease the film?

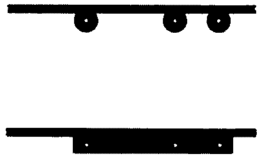

Fig. 4. "Squared-off" circuit pad.

Make a mixture of two parts white vinegar and one part isopropyl alcohol. About a cupful will do the job. Make two four-inch square pads using several thicknesses of cheesecloth and open the frame. Soak one cheesecloth pad in the mixture and sponge the screen thoroughly in its raised position using the vinegar/alcohol mixture. Wring out all excess moisture from the cheesecloth pad and close the frame over the film. Briskly rub the screen over the film surface with the dampened cheesecloth pad until the film underneath is thoroughly damp. Immediately use the dry cloth pad to blot up the moisture over the film. Use some pressure here. Don't rub—blot. This forces the threads of the weave into the softened emulsion. Areas that don't seem to be cooperating can be adhered by carefully reapplying the damp cloth and dry cloth in sequence. Take care not to over-soften and drag emulsion into "open" areas. Err on the side of caution until you get the hang of it.

Assuming your adhering job passes muster (uniform screen showing through the weave in all areas contacting the emulsion), let it sit for a while to harden. Open your frame. Starting at one corner, the one you scratched away to identify the emulsion side, gently peel off the mylar backing, watching all the while for areas that didn't quite stick to the screen. Go back and repeat the adhering process for those stubborn areas. By now, you should have a beautiful screen. Save the mylar; it makes a dandy dielectric for VHF work.

Now tear up a couple dozen strips of newspaper. Each should be about three inches by twelve inches. Run a 12-inch length of drafting tape along one long edge of a newspaper piece, overlapping the tape ½" over the paper. Starting ½" inside the film border, tape it down as shown in Photo B. Repeat for an adjacent edge. Continue around in a circle (square?).

When you have done four sides, continue around again, overlapping the tape over the previous tape strip until you have climbed up the inside of the frame and the entire inside of the frame is covered with what looks like solid tape. Why not use straight tape and forget the newspaper bit? You want as little as possible of the tape adhesive in contact with the screen. One, you want to prevent stressing the screen unduly when you remove the blockout when changing artwork; and two, you don't want to glob up any open screen with damn near insoluble hard-tape adhesive.

Whatever newspaper and tape is sticking up out of the frame you can trim flush with the top. Run a strip of tape around the inside of the frame and fold it over onto the top edge of the frame.

Cut a piece of circuit board as square as possible about a half inch larger than the finished board size you want. Run a file over the edges at a forty-five degree bevel to break off any sharp foil "zingers" that stick up. A barely perceptible piece of copper sticking up will slice up your screen or, worse yet, your thumb. Center the piece of copper under your screen image, leaving equal margins all around. Open the frame

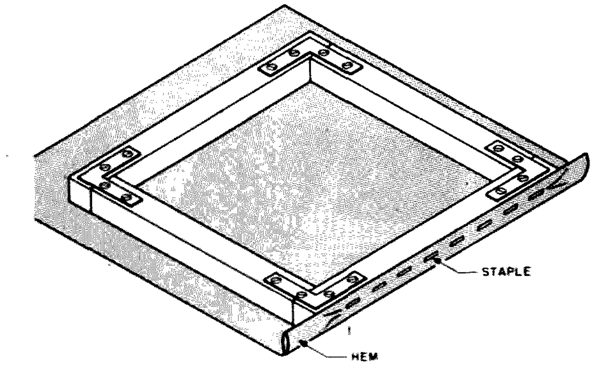

Fig. 5. Attaching the fabric to the outside edge of the frame.

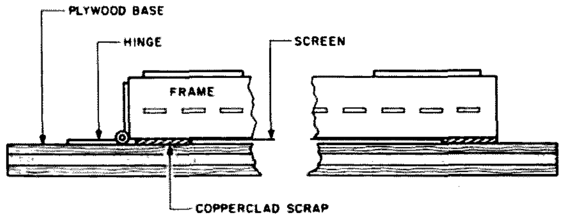

Fig. 6. Attachment of the frame to the plywood support.

without disturbing the copperclad. Take the four pieces of copperclad you used as spacers and securely tape one along each edge of the board to form a nest into which you can drop succeeding boards. Check to see that you didn't disturb anything and that your image still falls within the confines of the board. Remove the board and scour it shiny with the cleanser. Rinse in hot water and let it dry.

Open your ink can. The ink should be about the consistency of canned pudding. Stir it well with a tongue depressor or dull butter knife. Place the dry board in the nest. Close the frame over the board. Place about a 3/8" to 1/2" bead of ink on the screen along a short edge of the board about a half inch away from the border. Pick up your squeegee and with one slow, deliberate, firm stroke, drag the ink across the artwork past the opposite border. Put down the squeegee, open the frame, and gaze down on your perfect, ready-to-etch board. Carefully set your masterpiece aside to dry. Then make a few more boards, sell them to your friends, and charge plenty. Recoup your investment.

Thoroughly clean your screen and tools with benzene immediately after use. Use this stuff outside if you can; it's highly flammable. Make sure every trace of ink is removed from the clear areas of the screen if you plan to reuse it for this or any other project. Hold the screen up to the light; any blocked areas will show up soon enough. Etch your boards according to the etchant manufacturer's instructions. Clean the ink off the board with benzene or steel wool after you are done etching.

Want to print a different pattern? Simply peel off the newspaper blocking and dissolve away the old film with hot running water. Scour as before, adhere your new film, and repeat all other pertinent parts of the process. Several boards on the same screen? Why not? Simply block out the ones you don't want to print using tape and newspaper.

Is the underside of the screen gobbed up with ink or are you getting a fuzzy image during a longish printing run? Simply clean both sides of the screen thoroughly with benzene. Bad image on a board? Just wash the ink off with benzene and put the board back into rotation. Club projects? Ideal. While you're at it, why not print up some really neat club T-shirts or some really professional signs for the next flea market. QSLs? A cinch in any color, including rainbow.

Now what about those boards that are literally a can of worms and could not be cut by hand even if your life depended on it? These are still most economically done by the silk-screen process. Most large cities have companies which specialize in preparing printing screens photographically (see reference at end). Simply send them your artwork and frame and in a week or ten days they will return your absolutely flawless screen for less than the price of a full-size photographic transparency.

Double-sided boards? No problem. All double-sided boards have registration marks. Print your first side as described making sure to include the registration marks. Clear out your screen and adhere to the reverse side. Using a common pin, prick through the centers of the reverse side registration marks into the plywood platen. Drive two small brads into the plywood at the pinpricks so that just the heads protrude a little less than the thickness of the circuit board. On the now dry boards on which you just printed the first side, drill through the registration marks with a drill just large enough to clear the heads of the brads. Drop the boards over the brads, printed side down, print the other side, and etch the board.

What else can you do with this little marvel? How about front panels? Make up some scale artwork using Presstype or LeRoy lettering and ink. Have a photographic screen made, either positive or negative—your choice, just advise the screenmaker. Use your imagination. Using copperclad and a negative screen, etch away the lettering. Brightly polish the remaining copper and backlight the panel. The lettering will show up in a subdued green glow. Stunning! Using the positive and double-sided laminate, you will have copper letters and a green insulated panel. If you don't etch the backside, you'll have electrical integrity to boot.

Aluminum panel? Absolutely! Make your layout, screen print it on, and leave the ink on. Etch your panel with lye first as described in the *Radio Amateur's Handbook* or obtain a piece of brightly polished aluminum, screen print it, then etch the aluminum as above. Wash the ink off with benzene after etching and stare at the most strikingly beautiful panel you ever saw—polished raised letters on a satin background.

Once you develop skill with this technique, it will take you less time to produce things with this method than it did to read this article. You will soon be using this method in ways that would amaze even the author. For those of you who might feel that this technique is complex, I teach this technique routinely to Brownies and Cub Scouts who seem to have absolutely no problem making really cute stuff with screen printing.

Finally, I stand ready to answer any and all queries in exchange for an SASE. ■

SSTV. What follows is a simple means of obtaining hard-copy pictures from your SSTV camera, using a KIM-1 single-board microcomputer. The method should be adaptable to other micros using the 6502 microprocessor.

If you're still with me, I presume you have an SSTV camera and a computer with printer. The only other item needed is an 8-bit A/D (analog to digital) converter. You'll have to make a single tap into your camera to obtain the picture information. Incidentally, there is no reason why one could not obtain that signal from the SSTV monitor circuitry so that hard-copy pictures could be printed out from signals received over the air.

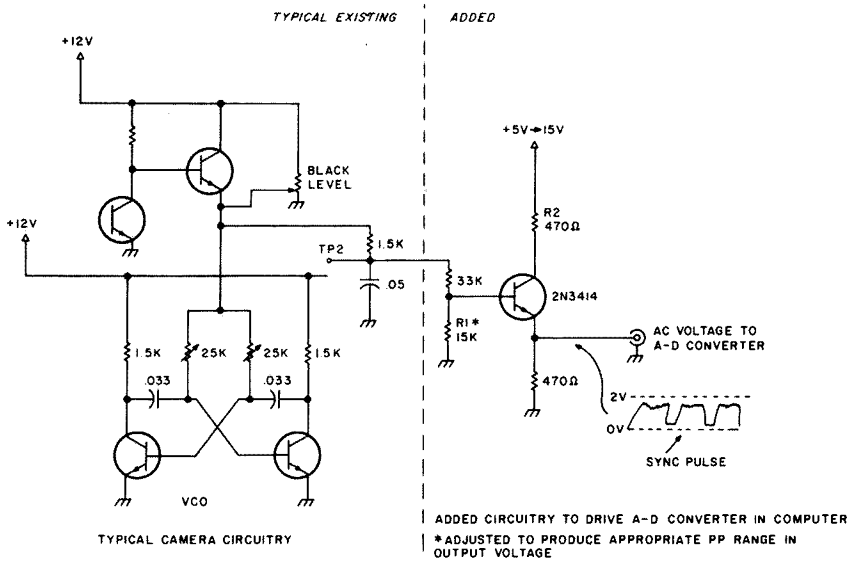

Fig. 1. Emitter-follower circuit used to drive A/D converter from SSTV camera. Alternate values for R1 and R2 are discussed in the text.

Hardware

First, let's talk printers. The typical garden-variety 80-column printer may not give you what you consider an adequate picture unless you can decrease the horizontal and vertical pitch. Pictures printed on a standard LA-36, for example, are not very impressive. I own an LA-34 which has programmable pitch. This is what gives the density and contrast necessary for a picture which is at least adequate. I've seen commercial setups in which the printer double-prints each line, overstriking each character to enhance its density. In the case of the LA-34 and other programmable printers, picture density and contrast can be enhanced by decreasing the horizontal and vertical pitch as much as is possible—in my case, 16.5 characters per

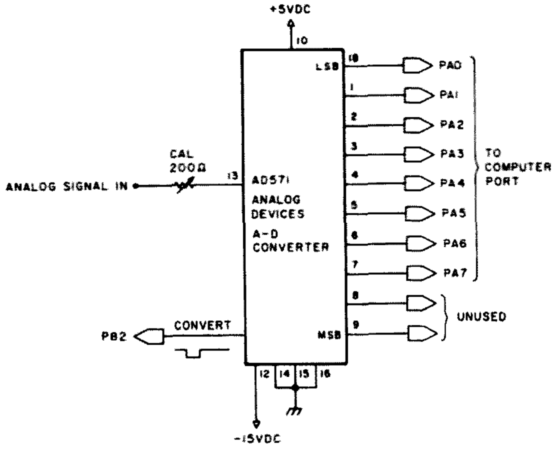

Fig. 2. A/D converter. PA0–PA7 and PB2 are input/output port connections on the KIM-1 microcomputer. The two most significant bits of the AD 571 A/D converter are not used.

Fig. 3. Hard-copy picture produced by dot-matrix printer set for 16.5 characters per inch horizontally and 12 lines per inch vertically.

inch horizontally and 12 lines per inch vertically.

The idea is quite simple. Somewhere in your camera there is likely to be a dc voltage which varies with brightness. In my case, I use an old Dage CCTV camera with a Hal Devices converter. There is a very convenient dc voltage which drives the vco (voltage controlled oscillator) in the Hal converter which I tapped for this purpose. As shown in Fig. 1, I used an emitter follower to provide for minimum loading of the converter and stiff drive. This voltage rises and falls in proportion to the brightness level as the camera circuitry sweeps the vidicon horizontally across the picture, and, indeed, even reflects the horizontal 5-millisecond sync pulses which trigger each new line. All we need to do is convert this voltage to a digital value by the use of an 8-bit A/D converter and store this information in memory.

I used the circuit of Fig. 2 to perform the conversion task. It contains a 10-bit A/D converter, but I used only the least significant 8 bits. This limits the voltage conversion range to 2.55 volts. Thus, the emitter-follower circuitry I use tailors the video signal so that it spans slightly less than 2.00 volts. There is no reason why a different voltage range could not be accommodated by slight modifications to the circuitry shown in Fig. 1. If you have an 8-bit converter available, you probably have a resolution of about 40 mV. You would want to change my emitter-follower circuit (Fig. 1) to provide a greater voltage swing fed to the A/D converter so as to preserve gray-scale resolution. Try increasing R1 and eliminating R12 and increasing B+ to 10–15 volts.

The AD571 converter which I use is relatively expensive but easy to use. The eight LSB outputs are connected to PA0–PA7, and the blank-and-convert pin is connected to PB2. The outputs on port A are tri-stated until PB2 is driven low, commanding the converter to do its thing. After 25 microseconds have elapsed, the data on Port A represents the analog input in digital form. The sequence is then (1) pull PB2 low, (2) wait for valid data, (3) read and store data on Port A, and (4) push PB2 high again.

Software

The software (see Listing 1) occupies less than one page (256 bytes) of KIM-1 memory plus one additional page for the character lookup table. The routines are straightforward and documented in the listing. The program consists of four sections: (1) clear memory, (2) acquire data and store in memory, and (3) recall data and print character from (4) the lookup table. I used pages $31–$5F to store data, but any 12K block can be used by making the appropriate changes in the software.

Since an SSTV picture is approximately 125 lines from top to bottom, it's logical to store about that same number of values across each line since little improvement in resolution can be had by increasing beyond 125. The KIM-1 onboard timer is used to space the video samplings by about 530 microseconds. Simple math reveals that 125 samplings of 530 microseconds each is a time duration of about 66,000 microseconds. At a horizontal sweep frequency of 15 Hz, each sweep takes about 66,000 microseconds, so our delay is about right.

The software simply samples the dc output of the camera each 530 microseconds until all 12K of memory is filled. It then proceeds to reset the pointers and read the values out sequentially.

Operation

Once the hardware is connected and the program loaded, start the sequence at $2F00, but wait until the camera vertical sweep is at the top. In my case, I address $2F00 and watch the SSTV monitor, punching GO on the KIM-1 keypad as the vertical sweep begins a fresh sweep. After about 8 seconds have elapsed, the printer will print CR/LF several times and then begin printing line after line of the picture. At the conclusion, the computer reloads the starting address of the program and jumps to the KIM monitor.

My first few attempts at printing pictures immediately revealed that the aspect ratio was way off—that is, the picture was not square or even close. Happily enough, the error was almost exactly 2:1; the picture was twice as long as it should have been for its width. The solution was simple: print every other line. The program watches for a sync pulse (sync pulses in my camera deliver a voltage less than $3C), so it was simple to wait for a string of values less than $3C and then begin printing. In order to print every other line, one merely prints past the next sync pulse by loading a value in LINECOUNT which ensures this. The software waits for the "next" sync pulse before beginning to print again. This seems to work well. Incidentally, this threshold value will probably differ with each hardware setup, so be prepared to modify the value found in addresses $2F7E and $2F85 to be just a few counts larger than the digital value returned by your A/D converter for camera sync pulses.

Which character do we print? Early in the game I used my BASIC interpreter to print every ASCII character in 8 lines across the page. This printout was viewed from a distance and my subjective judgment selected the following characters, starting with the least dense and growing toward the most dense: $20 (space), $60 ('), $27 (,), $2E (.), $3B (;), $79 (y), $6F (o), $6E (n), $53 (S), $4E (N), and $40 (@).

These characters are placed across page $30 of memory. The hashing technique is used whereby the video value retrieved is used as the address in page $30. If, for instance, the A/D converter returned the value of $50, then the program looks at $3050 and prints the ASCII character stored at that address. The spacing and placement of the characters was done by experimentation and can be adjusted easily by the user to meet individual camera characteristics. Since my camera gives minimum voltage for black and sync and higher values for bright and white, the values in the table are arranged this way, with the (@) stored in the lower addresses and the (.) stored in the higher addresses. If a camera gives the reverse, namely, a lower voltage for a brighter level, reverse the order of the stored values in page $30.

It is unlikely that my placement of values in the lookup table will suffice for your camera, so let me suggest the following: Manually load the table with my suggested values, starting at $3000, loading 25 each of the ASCII characters until you reach the top of the page at $30FF.

Focus the camera on a photo having a nice range of grays and including full white and full black. Start the program at $2F00 and then look at the values stored in the 12K of RAM. Note the minimum and maximum values found. These represent the sync-through-white range of your camera. If sync is returned by your converter as, say, $20, and full white is returned as $61, then you know that all values converted will fall within this range. Your lookup table values will be evenly spread from $3020 to $3061, and addresses above and below this range may be loaded with $00 since, theoretically, they will never be used. Note that you may adjust the placement or dispersion of values across the range to account for individual camera characteristics. If, for instance, you want more contrast, then load fewer of the numbers for the center of the gray scale, namely, fewer $79s and $6Fs, making up for this decrease by increasing the occurrence of numbers near the ends of the range.

As with any such picture, it must be viewed from a distance to disallow the eye from reading the individual characters and enhancing the overall picture. The lighting of the subject is a very important consideration, and users should experiment. In general, use a hair light directly above the subject and light the face more from one side than the other. Avoid direct frontal lighting as this flat lighting tends to hide the features. Fig. 3 shows a typical printout.

I've had more fun than I anticipated, producing a hard-copy picture of a visitor and giving it to him to take home. People seem to deem this a reasonable justification for having a computer, and if you're anything like me you need every justification you can get to cover your expenditures of time and money.

I've just begun to experiment with this technique and no doubt many improvements will be made to what I've started here. I'd be most interested in hearing from others who have found ways to improve it. ■

Save Your Signal with Forward Error-Correction

In a hostile signal environment, you need all the help you can get.

There have been several short articles on packet radio over the past few years, but this article will present some different ideas on using computers to obtain error-free transmission of digital data over poor-quality radio channels (see "Computers and HF," *73 Magazine*, January, 1981). The current efforts in setting up packet networks share several things in common. They all use rather large blocks (about 260 bytes), and they all use error-detecting codes with no forward error-correction capability. Since these systems are being set up to make use of the specialized integrated circuits that are being produced for the commercial market, this result is to be expected—the commercial market uses the telephone system for its long-haul communications, and these types of packets will probably work very well on a phone line or on a radio channel that acts like a phone line.

A good quality VHF radio channel, or a VHF repeater channel, behaves very much like a telephone channel when it comes to bandwidth, level stability, and noise bursts, so it is reasonable to expect these packet systems to work fairly well in these cases. Considerable effort has gone into commercial research on this topic, so it is probably smart to follow their recommendations—when our radio channels act like phone lines.

On the other hand, a normal HF radio channel does not act very much like a telephone channel. On a typical day one can expect noise bursts every few seconds, deep fading, and lots of interference from other signals. In short, the channel is much more "hostile" than a repeater channel, and many more transmission errors can be expected per unit time. This means that for a packet system to work, it will be forced to transmit only very short packets in order to get some passed error-free between noise bursts and interference. In this mode, the framing and control bits added to the data in a packet become a very significant overhead and greatly reduce system throughput.

Another problem with the packet approach as it stands is that only one packet at a time is sent to the receiving station, and the sending station must wait for an acknowledgement of correct receipt before sending the next packet. On a very long HF path, or especially on a satellite path, that requirement can add significant delays to the process. Under these circumstances it would be desirable to send several blocks of data in one transmission, and then allow the receiving station to selectively request retransmission of only those blocks that it received garbled.

I have been working on a different approach to the problem of sending digital data over poor-quality radio channels for the past year. It uses shorter blocks and a code which allows forward error-correction so that it can function effectively under the most severe conditions. I expect it to work much better than packets over HF and satellite paths.

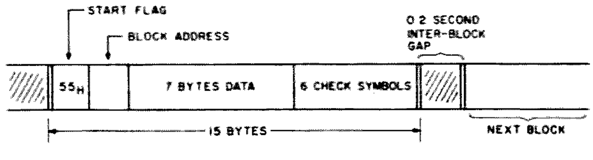

Fig. 1. Encoded block format.

Approach

This scheme has been set up primarily for the single-station-to-single-station mode of operation, as opposed to the multi-user, shared channel operation of a packet repeater. All coding and decoding is done in software, and standard asynchronous RTTY modulators and demodulators are used. The coding and block format would work just as well, however, if synchronous modulators and demodulators were used.

The system transmits 8-bit bytes as its data, allowing either computer machine code or ASCII text to be accommodated. The communications channel is assumed to be very noisy and prone to interference and fading (a typical HF channel under bad conditions). Since errors are assumed to occur very often, a system of forward error-correction is used.

As opposed to the cyclic redundancy check (CRC) used in packet schemes, where a packet must be retransmitted when one or more errors are detected in a block, a forward error-correction scheme uses several additional check symbols transmitted along with the data to allow it to detect and correct (up to a point) transmission errors within the data. Only when more errors occur than the code is capable of correcting must a block be retransmitted.

To allow the sending station to transmit several blocks before pausing to listen for acknowledgements, an "address" field is included in each block. This

Fig. 3. Output under severely degraded conditions.

8-bit number is uniquely assigned by the transmitting station to each block to identify it. The receiving station then acknowledges receipt of a block by sending its address. Those blocks that are not acknowledged (their addresses are not received back at the transmitting station) are then retransmitted. This feature allows up to about 256 blocks to be transmitted in a single transmission before pausing to listen for acknowledgements from the receiving station. This way, the long transmission delays of a satellite channel will not be nearly as costly in throughput.

After some analysis and experimentation, a twice-interleaved Reed-Solomon code of length 15 was chosen to encode each block of data. This code takes 9 bytes of data, computes 6 unique check symbols, and transmits them together as a block of 15 bytes. As shown in Fig. 1, each block begins with a start flag (55H), a block address byte, and 7 data bytes. The final 6 bytes of the block are the check symbols used by the decoding software for error-detection and -correction. The use of 6 check symbols allows the *correction* of up to 3 errors anywhere within the 15 bytes of the block, and *detection* of a garbled block when more than 3 errors occur. To give the decoding software ample time to correct a garbled block, a 0.2-second steady mark is transmitted between blocks.

Block transmission times (including the 0.2-second inter-block gap) are about 1.7 seconds at 110 bps, 0.7 seconds at 300 bps, and 0.32 seconds at 1200 bps. If the transmitting station chose to transmit a full 256 blocks before its pause to listen for acknowledgements, the maximum time per transmission would be about 7 minutes at 110 bps, 3 minutes at 300 bps, and 1-1/2 minutes at 1200 bps. These are all convenient transmission lengths to avoid abusing transmit/receive relays in the transmitters.

By using comparatively short blocks and incorporating forward error-correction, this system has the ability to function effectively under conditions much worse than those which can be tolerated by a normal packet system. Since 3 out of every 15 characters in a block can be garbled and still allow the block to be corrected to full accuracy, no blocks need to be retransmitted if the channel error rate is always 20% or less. In contrast, the packet system will require a retransmission whenever even a single error is experienced in a block. The net effect is that many fewer block retransmissions will be required for this scheme under poor conditions.

In exchange for this added capability, one must realize that even under the best conditions, only 7 out of every 15 characters are real data, and one now also needs additional coding and decoding software to use the system.

Example Decode

A program was developed to test the encoding and decoding functions, and sample output from this program is shown in Figs. 2 and 3. The test program takes a prepared list of 6 and 7 character words or easily recognizable sequences, encodes these using the proper format, and sends them to the local transmitter as an FSK signal. The transmitter is operated with its oscillator only, and the local receiver is tuned to demodulate the test signal. This signal is then recorded on tape and represents a noise-free example of a sequence of properly-encoded data blocks.

To test the decoder function, the tape is replayed, but the recorder output is mixed in with noise from the same receiver tuned to an unused area of an HF band. The noise level from the receiver is then adjusted until the demodulator is producing garbled output much of the time. The test program prints out the raw received data block, and also the data after it has been processed by the decoder. Often the decoder can be observed to have successfully corrected a badly garbled block.

Fig. 2 is an example of program output under ideal, no-noise conditions. The left column is the raw received 15-character data block, including the start flag (it prints as a "U"), the address field (prints as a blank), the 7 data characters, and the 6

check symbols. The check symbols look like random garbage, but rest assured that they have meaning to the decoder! The right column is the character sequence that is output from the decoder. In this no-noise case, every block is correctly decoded, of course, and, indeed, even the raw data is error-free.

The output shown in Fig. 3, however, is after the noise level has been increased enough to cause all blocks to sustain several errors. (At this noise level there were also several blocks where more than the allowable number of errors occurred and, as expected, the decoder was not able to correct the data in these cases.) By comparing the raw data block, with errors, to the decoder output and to the known correct block in Fig. 2, one can see that the decoder is often able to correct the blocks. (Not shown in this listing, but extremely important, is the decoder flag that indicates when it has detected a bad block that it could not correct. Each of the blocks that were not successfully decoded would have had this flag set.)

Fig. 3 also illustrates that the decoder can not only correct several errors in a block, but also it can often correct a block when the start flag was so corrupted by noise that the received data is not in the proper position within the block.

Networks

This system is optimized for station-to-station links and HF channels, while packet systems are optimized for VHF repeater and multi-user channels. This does not mean, however, that the two cannot be mutually beneficial. For local networks, using high-quality repeater channels, the packet scheme alone would be used. But for those HF or satellite links where data is being passed between isolated packet networks, packets could be transferred by breaking them up into the smaller blocks required for the forward error-correcting scheme and sending them to the receiving station as a series of these smaller blocks. At the receiving station (a "gateway" into the receiving network), the blocks would be properly assembled to restore the packet, and the packet would be introduced into the local network like any other. Unless one is blessed with a very good HF channel, this approach will probably be more successful than attempting to transmit the packet, intact, over the HF or satellite link.

Conclusions

A complete software system incorporating this error-correction scheme has been completed for amateur digital communications and has been in use (on the air) for almost a year by the time this is printed. While it is still undergoing changes and enhancements, it is already a very viable system and provides greatly improved communications over standard RTTY.

The existing software is written for Digital Group Z-80 computers and requires a minimum of 26K memory. It requires only conventional RTTY interface hardware and is available from the author.

Further refinements are planned for the system, including incorporation of a hardware interface board to simplify the software and allow higher speed operation (up to 9600 bps) while making it easier for people operating other computer systems to use the system. ■

We're changing what repeaters can do . . . for YOU!

Whether you're a repeater owner, control op, or user, the RC-850 controller offers you capabilities you've only dreamed of. Like natural sounding speech synthesis . . . easy, remote Touch-Tone programming . . . talking meter readback . . . synthesized remote base operation . . . and an autopatch with features you have to hear to believe.

Most important of all, upgrade through software, prevents obsolescense. Which lets us bring you new features, like our scheduler, for automatic changeover of repeater status by time and day of week . . . And our mailbox, for leaving messages for your friends. Plus much, much more!

The RC-850 Repeater Controller—The New Standard in High Performance!

Ask anyone that owns an RC-850 controller. Or ask us for our demo tape, so you can hear for yourself.

A Colorado-Style Battery Monitor

Texas has its barbecue and Chicago its pizza. Colorado's claim to fame is this near-perfect device.

Lynwood H. Wilson
Jamestown Star Rt.
Boulder CO 80302

A battery monitor should tell you when your battery is in trouble, but it shouldn't make trouble for your battery. The ideal device (all the books start with the ideal device, don't they?) draws no current when the voltage is good and draws as little as possible to warn you when the voltage is low. This circuit approaches the ideal, drawing less than 30 uA in normal operation and about 3 mA when flashing the LED.

A big factor in the low power consumption of this circuit is the 3909 flasher chip. An LED can be a heavy load for a small battery, but a flashing LED draws less power and more attention. The 3909 is designed to be an LED flasher, to operate on voltages as low as 1.5, and to draw minimum current. It is also usable as an oscillator, an amplifier, and who knows what else (it's one of those!). So check the National Semiconductor *Linear Applications* and enjoy yourself, but this time (surprise) we are using it as the designer seems to have intended.

The circuit is straightforward, and values are not critical. I used 2N3904 transistors throughout, but I suspect any low leakage silicon NPNs would work. The capacitor sees a voltage reversal of 1.5 V each cycle and probably should be rated for it, but I used an ordinary electrolytic and it's been working fine for some time.

Voltage from the divider, R1 and R2, normally holds Q1 on, which sinks the current through R4 to ground, holding the Darlington (Q2 and Q3) off. When the battery gets tired, the voltage to the base of Q1 falls too low to hold it on. The current through R4 is thus available to turn on the Darlington. Pin 4 of the IC is pulled down to ground, and the LED (any LED) begins to flash. The value of R5 should be large enough that pin 2 does not go more than 7 V above pin 4 with the input voltage you are using. R5 controls flash rate and current drain.

My monitor keeps watch on a 9-V battery and seems to work quite well at 12 V, but for higher voltages, R1, R4, and R5 can be increased in value. R2 sets the limit voltage, and it is a bit tricky to adjust. It is much easier if you use an adjustable power supply rather than a voltage divider to get the source voltage, since the difference in current from on to off can change the output of a voltage divider enough to make you think you'll never get it right. Never mind how I know. ■

The Totally-Modified 2000

Take Azden's popular 2-meter rig and add all the extras you ever wanted.

The PCS-2000, Azden's first radio on the US amateur market, is an extremely popular 2-meter FM rig. There have been numerous modifications for this transceiver—adaptations for various specialized situations—and this article is a compilation of them. Amateur-Wholesale Electronics receives a lot of inquiries about PCS-2000 mods. Here they are.

The modifications described here include PL™-tone installation information, a full-band-scan mod (in case you want to scan across 144-148 MHz in one sweep instead of in separate 1-MHz sweeps), a nicad memory backup mod, and CAP/MARS mods. Other modifications have been done; the Up, Down, and M1 Call buttons on the microphone, for example, may be rewired to perform other functions. Here, we will give details only for the aforementioned four modifications of the PCS-2000, since they are by far the most common and most asked-for.

PL-Tone Installation

The PCS-2000 needs an external tone oscillator for PL use. Any PL-tone generator may be used. Tone injection is done on the PLL board, which is on the top of the rear section, toward the front. (The board number is 50-30160.)

Look near the center of this board and locate the space for R159—it is vacant. Install a resistor of 22k to 47k Ohms in this space. Near R159, there are two holes with white circles around them. One of these holes is next to R124 and R127—this is ground. The other hole is for PL-tone injection.

Full Band Scanning

The PCS-2000 microcomputer is programmed to autoscan in steps of 10 kHz, within one of these four ranges: 144-145, 145-146, 146-147, or 147-148 MHz. Depending on the MHz digit at the time scanning is begun, the PCS-2000 will remain inside one of these ranges. This is convenient, since it allows the receiver to cross a given frequency four times as often as would be the case if the scan range were a full 4 MHz. Thus it is less likely that a short transmission will be missed entirely. This narrow-scan feature also reduces the number of unwanted channels that are scanned.

However, sometimes it is desirable to scan the entire 2-meter band, perhaps because the local repeaters are on widely separated frequencies, or because you may not know where they are (on an extended trip). This can be done manually by hitting the MHz Up key just as the microcomputer gets to the top of its 1-MHz scan range. (It takes good timing!) But we can easily get a couple of ICs to do this for us. The circuit is given in Fig. 1.

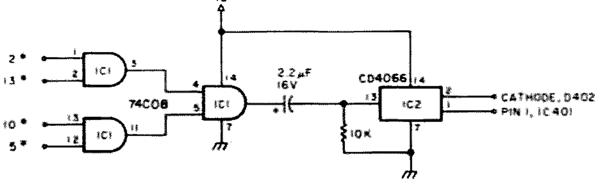

Fig. 1. Full-band-scan modification for the PCS-2000. The circuit is wired to the control board, which is the circuit board on top of the control head. External connections marked with an asterisk (*) are pin numbers for IC402. IC1—74C08; IC2—CD4066.

This circuit is connected to IC401, IC402, and associated circuitry on the control board, which is located on top of the control-head section of the PCS-2000. External connections should, of course, be made to the underside of the board; the board is easily removed for this purpose. Ground connections should be made to the common bus on the board. This entire circuit can be built on a piece of perfboard about 1 inch square. The best place for the completed circuit is right behind the Offset/Scan switch PC board. Proper insulation measures should be taken to avoid short circuits between circuit boards.

When this modification has been installed, the Autoscan key will cause the PCS-2000 to scan across the range 144.000-147.990 MHz in increments of 10 kHz. If the 5k Up button is activated, the range becomes 144.005-147.995 MHz, again in steps of 10 kHz.

Nicad Memory Backup

Failure of any of the three little silver-oxide memory backup cells can give the illusion of a rig in need of drastic repair service. The most common symptom is activation of the memory-scan function after a transmission; there also may be false or strange readings on the frequency display. Removing the memory backup cells will eliminate these horrible manifestations, but of course you have to re-

place the cells if you want the memories retained while the radio is off. The silver-oxide cells (type 76) can be found in most camera shops; however, there's an easier way to replace them—easier in the long run, because you shouldn't have to tamper with them again for several years.

A special nicad battery is available from Amateur-Wholesale Electronics. It is used in the PCS-3000 unit, but will fit into the PCS-2000 without much trouble. It is moderately priced (less than three new silver-oxide cells). You'll also need a 1000-Ohm resistor, available at Radio Shack stores for a few cents.

To perform this mod, remove the three silver-oxide cells from their holder and solder the leads of the nicad battery to the terminals of the silver-oxide cell holder. (Be sure to observe the proper polarity. Remember Murphy's Law—the chances of getting the polarity correct if you guess are *considerably* less than 50-50.) It is best to solder on the underside of the board.

Locate D408, adjacent to the cell holder. Solder the 1000-Ohm resistor across D408 on the underside of the board. This causes the nicad to be trickle-charged while the radio is on, at the rate of about 1.5 mA. It is recommended that the nicad from the PCS-3000 be used, since it is just the right size, physically and electrically, for this application. If another nicad is used, it should have a capacity of at least 50 mAh.

CAP/MARS Mods

Some confusion exists concerning the modifications for extended frequency coverage for the PCS-2000. There are two different modifications; which one you need depends on whether the transmitting and receiving frequencies are both on one side of the 2-meter band, or whether they are on opposite sides of the band. For Air Force and Navy MARS, both frequencies are generally on the same side of the band (for example, RX 143.460, TX 142.155). For CAP and Army MARS, the frequencies usually straddle the band (for example, RX 148.150, TX 143.900). This is shown in Fig. 2.

The PCS-2000 can be modified to reach frequencies as low as 142.000 MHz and as high as 149.995 MHz. (At the extremes of this range, there is some reduction in receiver sensitivity and transmitter output power.) When pin 13 of the TC9122 programmable divider is pulled low, the actual operating frequency goes either up or down by exactly 4.000 MHz, although the display reading does not change. If the display shows a frequency between 144.000 and 145.995 MHz, the new frequency is 4.000 MHz *above* the indication on the display; if the display shows 146.000 to 147.995, the actual frequency is 4.000 MHz *below* this indication.

Same-Side Splits: Air Force and Navy MARS

Cut the gray wire from pin 4 of connector L on the receiver board and solder it to pin 13 of the TC9122. Connect the three diodes as shown in Fig. 3 and run a wire from the anodes of D2 and D3 to the point marked "UL" on the control board (the top board in the control head). Cut the foil on the Offset/Scan switch PC board as shown.

Once these changes have been made, the radio will still work normally when the Offset/Scan switch is set to F, B, or V on the right-hand side, but on the left-hand side, pin 13 of the TC9122 is low, and the frequencies differ by 4.000 MHz from the display as previously described.

Position V on the left side

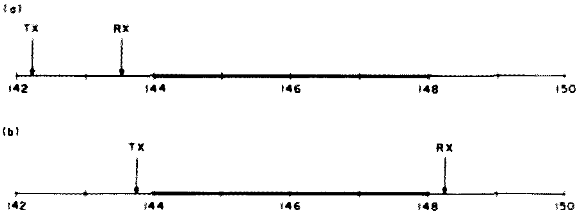

Fig. 2. Examples of same-side splits (a) and straddle spilts (b). The amateur band is shown by the heavy line. When modifying the PCS-2000 for CAP/MARS operation via repeaters, same-side splits and straddle splits require somewhat different circuits, as discussed in the text.

of the Offset/Scan switch will provide simplex operation. Positions B and F allow repeater operation when the proper offset crystal has been installed. (The display will not follow crystal-controlled offsets.) To obtain the proper offset, the original 17.9-MHz crystal, which gives an offset of +1.000 MHz, must be replaced. This crystal is located on the transmitter board, the larger board on the underside of the rear unit.

To determine the frequency for the new crystal, first determine the value of the offset, and whether it is positive (TX frequency higher than RX) or negative (TX lower than RX). Use the formulas: offset freq = TX freq − RX freq; crystal freq (MHz) = 16.900 + offset (MHz). For example, suppose you want to receive on 143.460 and transmit on 142.155. This is an offset of −1.305 MHz: offset freq = 142.155 MHz − 143.460 MHz = −1.305 MHz. Therefore, the crystal frequency must be: crystal freq = 16.900 MHz − 1.305 MHz = 15.595 MHz.

If the transmitting frequency is very far from the edge of the 2-meter band, the transmitter output power may be reduced. This is normal, since the circuit is tuned for the range of 144 to 148 MHz. Some transmitter retuning will increase the output at out-of-band frequencies. With the radio upside down and the front panel toward you, locate T107 and T108, just to the left of

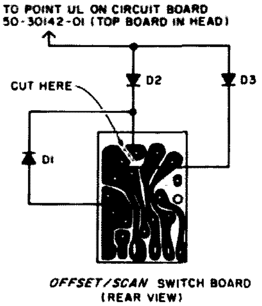

Fig. 3. Modification to the circuit board behind the Offset/Scan switch for same-side CAP/MARS repeater operation. Care should be exercised to be sure that the circuit-board foil is cut in the right place (it's easy to do it wrong) and that the cut is clean.

the 16.900-MHz crystal. These transformers may be adjusted with a small screwdriver to obtain somewhat more output. You can use the digital S/rf meter on the front panel of the PCS-2000, but it is better to use a wattmeter.

When retuning the transmitter in this manner, be careful to note the original positions of the transformer cores, in case you want to return the unit to normal. Also, do not over-adjust the transformers, since this will seriously degrade the power output in the amateur band.

If the offset required is more than 3.000 MHz either way, a different modification is needed.

Straddle Splits: CAP and Army MARS

To get larger splits, perform the modifications

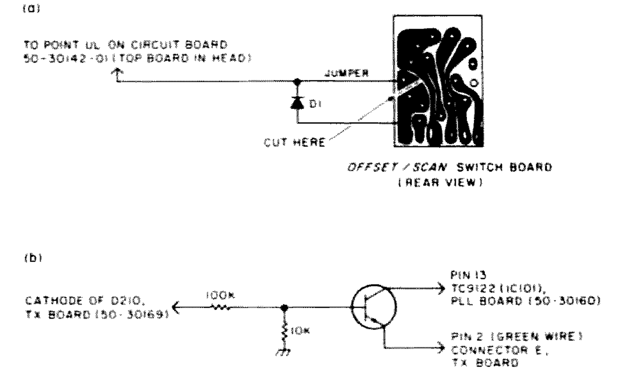

Fig. 4. Modifications for CAP/MARS straddle splits. At (a), changes to the circuit board behind the Offset/Scan switch; at (b), additional circuit to be installed. (The NPN switching transistor may be any common transistor suitable for digital or low-frequency applications.)

shown in Fig. 4. (Note that the change to the Offset/Scan switch PC board is different than for same-side splits.)

Once these modifications are done, the PCS-2000 will function normally when the Offset/Scan switch is in either B or V on the right-hand side. When the switch is in the F position on the right, CAP/MARS simplex is provided, on frequencies either up or down 4.000 MHz from the display frequency (as previously described).

Positions B, V, and F on the left-hand side of the Offset/Scan switch will provide CAP and MARS repeater operation with straddle splits, once the 17.9-MHz crystal has been replaced by one having the proper frequency.

To determine the new crystal frequency, use the following formulas: offset freq = TX freq − RX freq; crystal freq = 20.900 + offset (MHz), if offset is negative; crystal freq = 12.900 + offset (MHz), if offset is positive. For example, suppose you want to receive on 148.150 and transmit on 143.900. This is an offset of −4.250 MHz: offset freq = 143.900 MHz − 148.150 MHz = −4.250 MHz. Since this is a negative offset value, crystal freq = 20.900 MHz − 4.250 MHz = 16.650 MHz.

To operate on these frequencies, set the display to 144.150 with the Offset/Scan switch to the left of center. Then your receiving frequency is 148.150 MHz, and the correct offset (−4.250 MHz) will occur during transmission periods.

The arithmetic here is a little bit confusing, but following these instructions carefully should yield the desired results.

The NPN transistor and the resistors shown in Fig. 4 may be obtained at Radio Shack or any local parts supplier. The crystal should be parallel-resonant, 32-pF, with HC-25/U holder; they may be obtained from any crystal manufacturer. Frequency should be specified to within about 3 kHz, preferably to the nearest 1 kHz.

Conclusion

It is hoped that this information will enable owners of the PCS-2000 to derive more operating convenience from their rigs. Of course, there are many other possible modifications. These four, however, are frequently asked for.

I would like to thank Mark Thomas at Amateur-Wholesale Electronics for his assistance in compiling this information. ■

MICROLOG AIR-1

SPECIFICATIONS

INPUTS: Receiver audio, In & out phono jacks for easy speaker connections. Hand key input allows code practice that reads your sending and drives the transmitter keying outputs.

OUTPUTS TO TRANSCEIVER: Positive and negative switching for CW & FSK keying, solid state or tube type transmitters, AFSK tones at microphone compatible levels, T/R(PTT) transmitter control.

PRINTER OUTPUT: Uses standard VIC printer for "Hard-Copy" of both receive and transmit data regardless of on-the-air mode. Also has hi voltage transistor switch on board for driving current-loop type printers.

DISC & TAPE INTERFACE: Uses standard VIC DISC & DATASET for recording off the air and making long "brag tapes." Another handy feature is the ability to save and re-load your "here-Is" memories easily. Since this function is also compatible with your VIC disc drive, it's especially nice for quick start-up.

VARIABLE MEMORY UTILIZATION: A unique Microlog feature allows you to select the size of your text buffer and 8 "HERE-IS" messages from the available computer RAM. It automatically takes into account any memory expansion cartridges you've added. The unexpanded VIC has about 3000 characters for you to allocate. You could for example choose eight 300 character messages and a 600 character text buffer. If you don't tell it otherwise, the system will default to eight 100 character "HERE-IS" memories and a 2200 character text buffer. The expanded VIC will have different default memory sizes, depending on the amount of added memory. The programmable "HERE-IS" memories can be loaded or inserted into the text buffer for transmission at any time.

TEXT BUFFER: Allows you to type ahead while receiving. Text entered into the buffer is visible above the split-screen line for correction before sending.

AUTO-START: Inhibits the display of non-RTTY data.

TUNING INDICATORS: On screen visual tuning aid and audio (pitch) reference tone for RTTY and CW. (Audio is heard thru your tv or monitor's sound channel, just like any other VIC generated audio.)

W R U (Who Are You?): Automatically responds with your call sign when a user programmable sequence up to 15 characters is received.

SEL-CALS: Two 15 character user programmable sequences. Receipt of selcal #1 enables the printer, disc or tape. Receipt of #2 disables these outputs for unattended message store (mailbox).

FULL SPEED OPERATION: Transmit and receive Morse — 5 to 199 WPM, Baudot — 60, 66, 75, 100, 132 WPM, ASCII — 100 & 300 baud.

MORSE SPEED TRACKING: Automatic and speed lock modes, keyboard selectable.

VIDEO DISPLAY: Color keyed display makes optimum use of the computer's color capability. Uses standard VIC format of 23 lines of 22 characters.

SPLIT-SCREEN: Displays text buffer input above and receive/real-time transmit text below the split line.

TOP LINE DISPLAY: Constant display of Time, Mode, Speed/Code in use, and status indicators.

TEST MESSAGES: Quick brown fox and RYRY's in Baudot, U*U* in ASCII, and VVV in Morse.

SPECIAL SYNC-LOCK MODE: Allows improved ASCII operation and "Paced Output" in Baudot RTTY.

T/R(PTT): Fully automatic control of your XMTR via the Push-to Talk line in both RTTY and Morse.

UN-SHIFT on SPACE: Automatically shifts back to "LETTERS" upon receipt or transmission of a Baudot space. Keyboard command on/off.

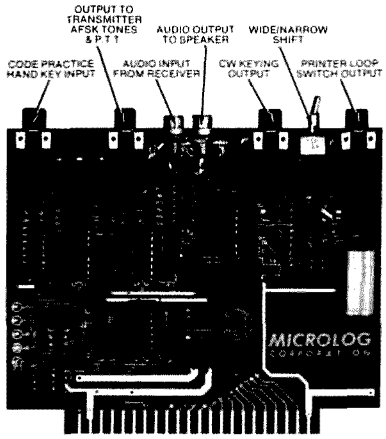
SYNC: Transmits "Blank Fill" in RTTY and BT in Morse when the text buffer is empty and unit is in transmit. Keyboard command on/off.

OUTPUT MODES: CHAR — outputs each character as typed. WORD — outputs full word when spacebar is typed. LINE — outputs full line when carriage return is typed. BUFFER — outputs full buffer, on command.

REAL-TIME CLOCK: Uses the VIC's internal clock for constant on screen display of time which can be inserted into text buffer on keyboard command.

WORD WRAP AROUND: Prevents splitting words at the end of a line. Works in receive as well as transmit.

MORSE TONE DETECTOR: Single tone, 800 Hz center frequency, with effective bandwidth of 300 Hz. Pitch reference regenerated audio tone for easy tuning.



RTTY DEMODULATOR: True dual tone computer enhanced demodulator circuit on standard 2125/2295 Hz tone pair compatible with HF RTTY and VHF FM operation. Switch selected wide and narrow shift.

CODE PRACTICE: Random five character code group generator sends at any speed you set via the keyboard. Hand key input for sending practice and manual morse transmission.

CW ID & NORMAL ID: Two independent 16 character memories for either 2 calls or one normal and one with auto-CW ID for RTTY.

MECHANICAL: Printed circuit board is G-10 epoxy, double sided with plated thru holes. Board is solder masked and silk-screened with parts locations for easy troubleshooting. Size is 5¾" wide by 4½" deep by ¾" high. Fits directly into VIC expansion port and is compatible with popular expander boards in use.

NO EXTERNAL POWER REQUIRED: Unit is completely powered by host computer, eliminating the need for outboard power supply. (Entire system; VIC, Microlog AIR-1, & video monitor can easily run from 12 VDC power for remote or emergency battery operation.)

CONNECTIONS: All inputs/outputs are convenient ¼" 3 circuit phone or RCA phono types. Mating plugs are all provided.

Note: VIC, VIC-20 and DATASET are trademarks of Commodore Electronics, Ltd.

Send Your TR-7800 to Obedience School

This Kenwood rig has some interesting habits — such as a slow scan rate. Can you retrain it in one easy session?

I was quite happy with my Kenwood TR-7800 transceiver until the day I happened to compare it with a Bearcat 210 scanner. I first noticed that the Bearcat 210 was scanning much more rapidly than the TR-7800. Since the TR-7800 scanning is completely controlled by the microprocessor, the only way to increase the scan speed is to make the microprocessor run faster.

The microprocessor clock rate can be adjusted by L1 on the control board. It is normally set for a frequency of 346 kHz. By removing the slug completely, I was able to get the clock frequency above 600 kHz. And sure enough, the scan speed had also nearly doubled, with no noticeable compromise in performance.

Another Bearcat 210 feature stops the scanning once a signal is detected and then automatically resumes scanning after the signal drops out. In contrast, the TR-7800 only stops for a short time when it finds a signal. Then the scan is restarted even though the signal remains. This was interesting, to say the least.

Since scanning can be manually started or stopped from the switches on the front panel, it is possible to electronically actuate these switches to change the scan characteristics. A circuit to do this is shown in Fig. 1. It consists of three one-shot pulse generators and two FET switches. Assume the squelch line (SS) goes high indicating the presence of a signal. This causes one-shot U2-B to turn on switch U3-B and close the path between E0 and B3 for about 100 milliseconds, turning the scanning off. When SS returns to a low level, U1 generates a two-second delay pulse which then triggers one-shot U2-A and closes switch U3-A between E3 and B0 and restarts the scanning. The rescan delay may be adjusted by changing the value of C1 or making R2 adjustable.

Since the tone switch was not being used for anything, I removed and taped the two wires going to it and then connected the switch to the scan-control circuit. When the switch is off, all the standard scan features are still functional.

The components will fit easily on a 1.2″ × 1.8″ circuit board and can be tucked into an open area behind the tone switch. Fig. 2 indicates where the lines may be attached and the color coding of the TR-7800 wiring. I found that a lead clipped from a ¼-Watt resistor could be pushed in-

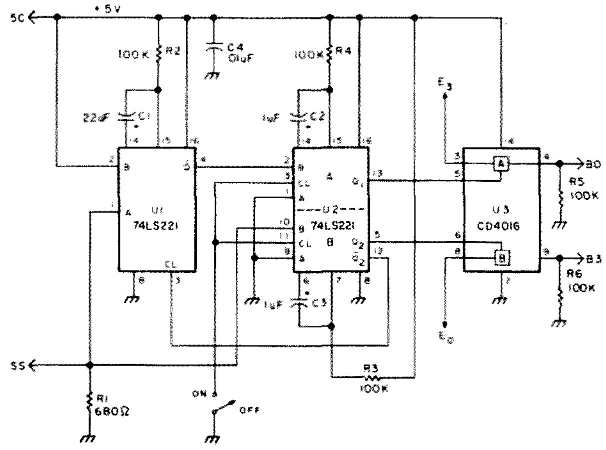

Fig. 1. Scan-control circuit.

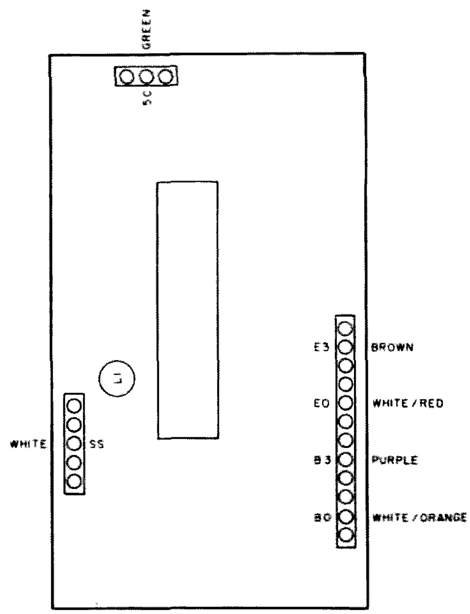

Fig. 2. Control board layout.

Fig. 3. S-meter circuit.

to the gap between the connector shell and the pin. This provides an easy way to tap into a signal line without cutting into the wiring.

An additional problem is that the five-LED S-meter does not give enough resolution for applications such as hidden transmitter hunting or antenna tuning. Fig. 3 shows a simple meter circuit which connects to TP3 on the receiver board. A calibration of the meter reading vs. input signal is given in Fig. 4. Signals greater than 100 microvolts cause no further increase in meter reading.

These modifications have made my TR-7800 more convenient and fun to use. These same changes should also work on the new TR-7850. ■

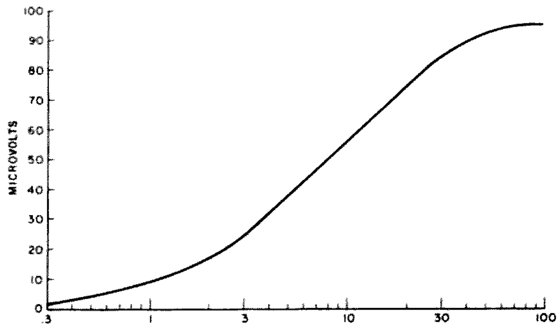

Fig. 4. S-meter reading vs. microvolts.

Do You Know Where Your Signal Goes?

It doesn't just sneak off your antenna and hide. Find out where your lobes are and what they look like with this simple procedure.

We hams will put up a new antenna for DX and then spend hours on the air trying to see how well it works. If it's a success, we're happy. If not, we may take it down and try something else. How many of us really know whether the directivity of our new sloper or single-loop quad is doing what we think it should? How many of us keep some record of an installation to compare one antenna's performance with another's?

Antenna pattern measurements of a rotary beam are easy to do. Set up a field-strength meter at your own or a friend's station, rotate the antenna, take measurements, and plot the results.

If it's a fixed antenna at the higher frequencies, 14 MHz and up, pattern measurements may be taken by walking around the antenna keeping several wavelengths from it. If measurements are taken too close to the antenna, the static field and the induction field will cause major errors in the desired radiation field measurements.

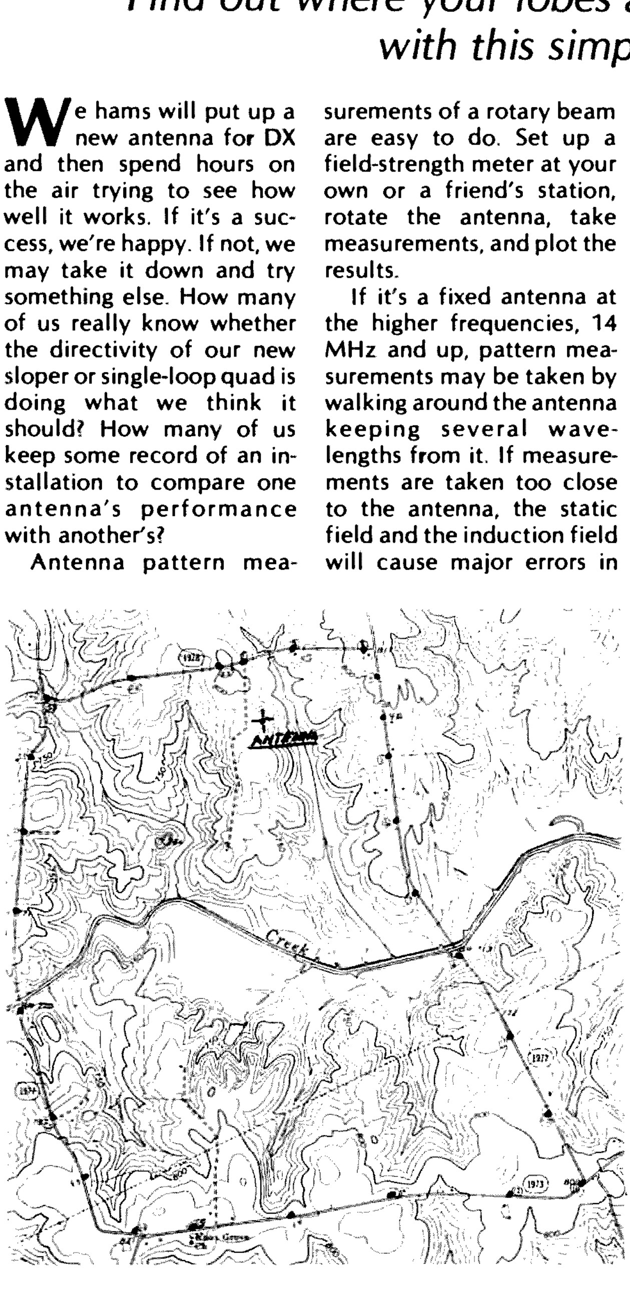

Fig. 1. Survey map showing antenna location and points where measurements were taken.

Several wavelengths at 80 meters, however, is approximately 700 feet, and there is a better way to get field-strength measurements than walking—and not many beams are rotatable on the 80-meter band.

Relative Antenna Patterns

The measurements to be discussed are of a relative nature and are not rigorous field-strength measurements. This statement is made early in the article so that qualified radio engineers will not be misled as to its technical thoroughness of field-strength measurements.

The IRE "Standards of Radio Wave Propagation—Measuring Methods, 1942"[1] states two basic methods of measuring radio-field intensities. These are mentioned to indicate what a technical field-strength measurement would be.

One method consists of measuring the voltage produced in a standard antenna by the field to be measured and computing the radio-field intensity from the measured voltage and the dimensions and form of the standard antenna. The other consists of comparing voltages produced in an antenna by the field to be measured and by a standard field.

In no way am I going to that trouble to determine a relative antenna pattern compared to another antenna configuration. If you are interested in absolute measurements, get the IRE publication; it's excellent. A comprehensive book, *The Complete Broadcast Antenna Handbook*,[2] has a chapter on carrying out field-strength measurements. Closer at hand, your own library probably, is W2YE's *Ham Radio* article[3] on the subject, or W2IMU's in *QST*.[4]

Read some of the above for background information. What will be discussed herein is a practical, unscientific method of determining a radiation pattern around your antenna. It is a repeatable measurement, and the technique can be used to compare other configurations of the same antenna or different ones. Nothing new is claimed for this method, but it has been a long time since such a detailed article on the subject has been published.

Let me (1) describe what was done, (2) discuss the results, and (3) conclude with the effectiveness of this method.

Tools Required for Measurements

The necessary tools to develop a 360° pattern of

your antenna's radiation are: (1) a map of the route around the area encompassing your antenna; (2) a receiver with a signal-strength meter tunable to the frequency at which measurements are to be made, and operable in an automobile; (3) a short vertical antenna which can be mounted on the roof of an automobile; (4) a power source isolated from the automobile power system (desirable, but not mandatory), and (5) an automobile or other means of carrying the equipment.

Location No.	Location Description	Distance from Ant. (Feet)	Bearing from North (Degrees)	dB above 1 uV	Micro-volts	Corrected microvolt (x 10,000)
0	Farm road & Rary Road	1200	0	38	80	9.6
1	Tonn Farm House	1450	24	41	120	17.4
2	Driveway, abandoned farm	2250	57	30	32	7.2
3	Chenault Rd., .1 mile south of Rary Rd.	2250	70	32	40	9.0
Etc.						

Table 1. Tabulation of measurement data.

Survey Map

A map must be used which has sufficient detail to show the roads and/or streets in your area. The Geological Survey charts[5] are excellent for this study. Lay out a route on the map which will circle the antenna site staying at least ¼ mile from the antenna for the 80-meter band and no more than 7 miles maximum. Wherever possible, stay within two miles, as the signal strength drops off fast as the distance from the antenna increases. Then lay out points on the map equally spaced around the area to be driven. Draw a line on the map from the antenna to the first point, and record 0 degrees and the distance from the antenna to that point. For every other point, with a protractor, determine its angle from the 0° point and measure distance from the antenna to that point. From the map scale, the distance should be in feet or meters. Twenty-six locations were used in the study for this article; see Fig. 1. A table (Table 1) was drawn up to indicate location number, a description of the location, and its distance and bearing from the antenna, as well as data to be recorded.

Receiver

The receiver may be anything that has a signal-strength meter, can work from a portable power supply, and is tunable to the antenna operating frequency. I could have used my TS-520 transceiver, but I used my HRO-500 receiver instead. It operates from 12 volts dc, is very stable, has a signal-strength meter calibrated in S-units up to S9, and a dB scale up to 40 dB. In addition, it has a dB scale calibrated in dB above 1 microvolt; 0 dB is the same as S1.

The dB scale has an advantage over the S-unit scale as it can be used more easily to determine microvolts, whose numbers are nonlinear as they increase relative to the dB scale. Each S-unit represents a certain number of dBs above some reference level, usually 1 microvolt. If you know how many dBs per S-unit for your particular receiver, you can calculate microvolts. If you use S-units for pattern plotting, you lose a certain amount of plotting sensitivity.

For example, using the S-meter gives nine points on the meter which are linearly spaced. Changing to dBs and thence to microvolts gives you a range from 1 microvolt to 100 microvolts for S1 to S9. Going from S8 to S9 is one division, but is equivalent to going from 56 to 100 microvolts. The plotted pattern is more sensitive to a microvolt scale than an S-unit scale. All patterns plotted herein are in microvolts vs. bearing angle.

Another example of S-units, dBs, and microvolts is shown in Table 2.

S-Reading	dB above 1 Microvolt	Microvolts
0	− 5	.56
1	0	1.0
2	5	1.7
3	10	3.4
4	15	5.6
5	20	10.0
6	25	18.0
7	30	32.0
8	35	57.0
9	40	100.0

Table 2. Comparison of S-readings, dBs, and microvolts.

Receiving Antenna

A vertical antenna mounted in the center of the automobile's roof is desirable. I used my 2-meter 5/8-wave vertical, which has a magnetic mount, until I found it had an intermittent in it. I then switched to a ¼-wave two-meter antenna mounted on the car roof-gutter which seemed to work just as well. The antenna was mounted on the side of the car facing the antenna under test. As the car went around the circle, it always presented the same configuration to the test antenna. It is thus believed that any directional characteristic of the automobile antenna system is a constant.

Isolated Power Source

Early measurements of the antenna under test were made with the receiver plugged into the cigarette lighter receptacle of the car. Because auto ignition noise produced an S1 to S2 signal, the ignition was turned off for each reading. As was my practice, the 0° first reading was repeated as the last reading. It was found that the reading read higher than when it was first read.

The complete run is 6.7 miles and takes about 30 minutes to complete. It is believed that the car battery voltage was lower at the beginning of the run and that the charging of the battery during the run produced a higher voltage at the end of the run. Perhaps this changed the sensitivity of the receiver; no other explanation was determined.

After connecting the receiver to its own 12-volt battery, it was found that ignition interference was eliminated and readings could be taken with the engine running. That saved wear on the starter in the car.

Another advantage of having the receiver continuously operating is the ability to maneuver the car to a proper stop point. It may be necessary to move forward or back up while watching

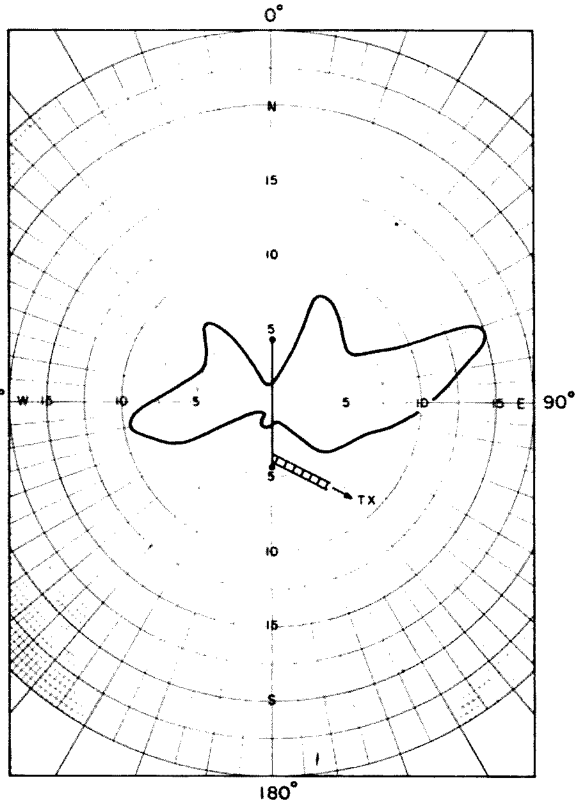

Fig. 2. Actual field pattern of an 80-meter full-wave Zepp antenna fed as shown, radiating over undulating land.

the signal-strength meter to prevent stopping at a point influenced by local wires. There will be a pronounced drop in signal strength if you stop beneath an overhead wire, for example. Even a utility-pole guy wire may cause amplitude interference to the test signal. Stop in an area where signal strength remains constant.

Solo or with Partner?

Do you run the test by yourself or with another ham? It would be desirable to have a friend at the transmitter operating site who would turn the transmitter on and off at your request. You could communicate using the transceiver in the car or by using a 2-meter setup.

Living in the country and being retired, I did it by myself. Fortunately, the 80-meter band between 9 am and 3 pm during the work week is lightly populated because of propagation conditions and normal work hours. I could put the transmitter on 3.8 MHz and run my test with no one knowing it. In crowded areas, a helper may be necessary.

The Transmitter

The transmitter used for the test was a Heathkit SB-100. It was desired to keep the signal output at a modest level since the transmitter would be on continuously for 30 minutes at a time. For ease of setting power input and monitoring it, 100-mA plate current was used. After adjusting the antenna tuner for minimum swr between the SB-100 and tuner, when used, plate current was adjusted by varying the grid drive. It was noted while on dummy load that initially the plate current would drop to about 95 mA after a few minutes operation. Grid drive would then be increased to give 100 mA and the plate current would remain there. The transmitter would then be switched back to the antenna to be tested and measurements made in the automobile.

Zepp Antenna Measurements

The first antenna to be studied was a full-wave Zepp antenna 240 feet long which runs on a north-south line. It is about 60 feet high at the northern end and about 50 feet high at its southern end. That antenna is used for communications on 80 meters and 40 meters. It is fed by a 600-Ohm open-wire line at the southern end. Theoretical field patterns state that so feeding it would produce four major lobes, a skewed cloverleaf with respect to the wire. The two northern lobes would be stronger than the two southern lobes. The desire for stronger lobes into the northeast was the reason for feeding the southern end.

The theoretical pattern is based on level ground beneath the antenna and a perfectly conducting one. The actual ground, especially to the east, is far from level; the ground drops from 800 feet to 750 feet and rises again to 800 feet in a horizontal distance of 1000 feet.

It had been possible to get S9 signals at close range with a vertical antenna used in preliminary tests with the SB-100 running at 75 Watts input. However, it was necessary to use about 600 Watts input with the Zepp to get comparable signals; a linear was added to the SB-100 output. Such is the difference between a horizontally-polarized and a vertically-polarized antenna with the receiving setup used.

Fig. 2 shows the results on the full-wave Zepp. It has four major lobes with the supposedly southern lobe horribly skewed.

Ground-Wave Attenuation

The data used to plot Fig. 2 was not the raw data obtained from the signal-strength meter. Using such data would provide a grossly distorted picture of the field pattern. Some sort of a signal attenuation factor must be considered, especially at the greater distances.

Reference 6 has an excellent chapter on ground-wave propagation. It points out that energy is abstracted from the surface wave to supply losses in the ground. So the attenuation of this wave is directly affected by ground conductivity and the Earth's dielectric constant.

The information in reference 6 is detailed enough to permit you to calculate the attenuation vs. distance relation. If you know your local ground conductivity and dielectric constant, you can be reasonably accurate on the attenuation factor.

Another approach is to recognize the additional error accrued by ignoring the above and saying, "Attenuation varies inversely as the distance."

Example: The signal strength at 1000 feet is 4.5 microvolts. What is the signal strength if no attenuation existed?

Solution: $S_c = S_a D$, where S_c = corrected signal strength (microvolts), S_a = actual signal strength (microvolts), D = distance (feet or meters); therefore, $S_c = 4.5 \times 1000 = 4500$ microvolts.

This was the method used to facilitate changing the raw data to plotting data. The rationalization to do this was that relative differences between configurations were desired, not absolute differences.

W2LL Antenna Measurements—Tower 1

In 1961, Gene Black, now W2LL, hit upon an odd antenna system for 80 meters which he had been using on and off and suggesting to friends. In 1972, he talked me into trying it. After getting my 100 countries on 80

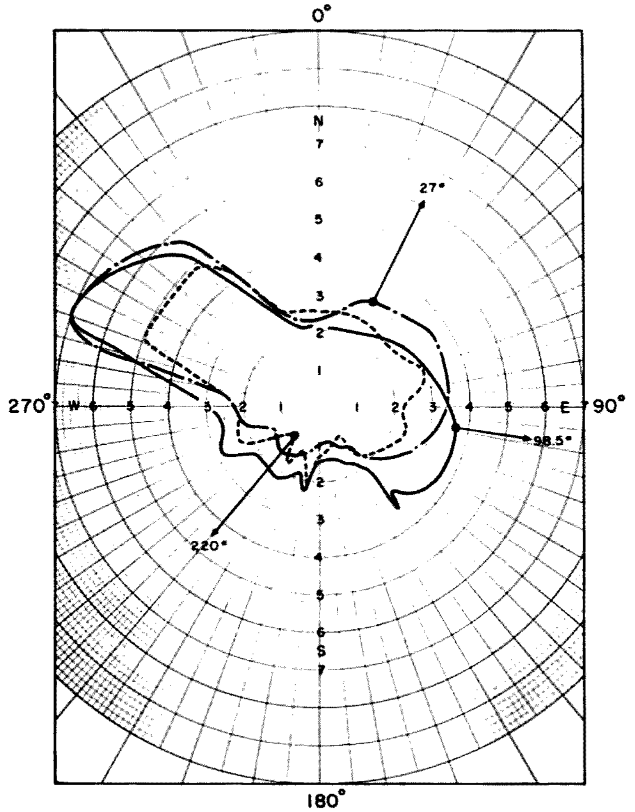

Fig. 3. Radiation pattern of W2LL antenna on number 1 tower which has multiple guy wires.

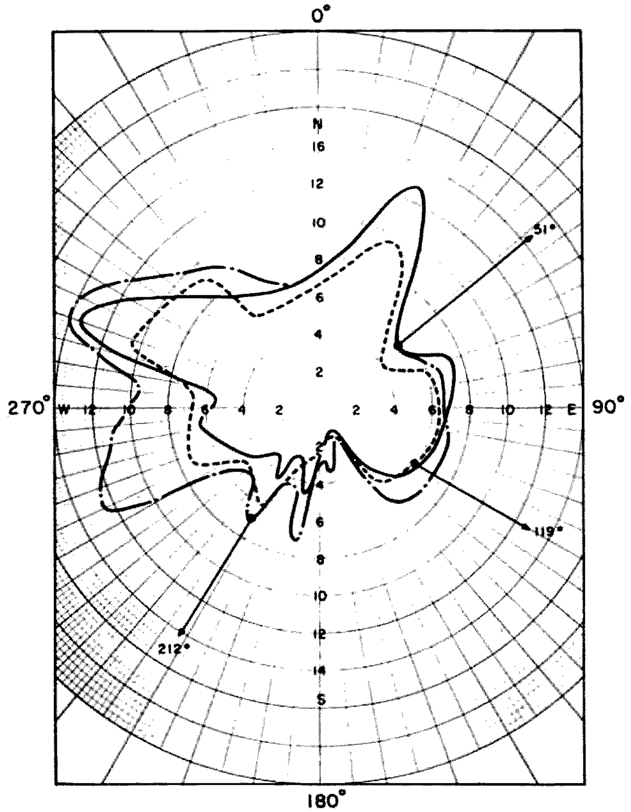

Fig. 4. Radiation pattern of W2LL antenna on number 2 tower which is free-standing.

meters as W2MB in NJ with it, it has been my favorite for that band. The antenna uses your high frequency tower and beam with an 80-meter quarter-wave horizontal or sloping wire. That wire is excited from the center wire of a coax line with the shield connected to the tower. It has currently become popularized by others and is called a quarter-wave sloper. Since that title imparts no real description of this antenna, and since I've always known it as "the W2LL antenna," I will so refer to it that way herein.

Incidentally, the secret for those who have weird loading problems and "it does not work" is to isolate the coax transmission line from the antenna system by use of a balun. One lead of the balun output goes to the quarter-wave wire, and the other is grounded to the tower. It will always work that way!

One characteristic of the W2LL antenna is an apparent directivity in line with the horizontal wire for systems that are electrically greater than a quarter wave. W2LL has noted, when using the system on 160 meters where it looks less than a quarter wave with his tower, that directivity is opposite to the direction the horizontal wire is pointed.

Since a new W2LL antenna was being put in at my new North Carolina residence, I wanted to see how the 80-meter directivity followed the changing of the direction that the horizontal wire was pointing. Also, would I be better by having two or more horizontal wires connected simultaneously? Hence these measurements.

The tower used is 50 feet high and has a steel pole extended above the tower to place the TH6DXX tribander beam at 60 feet above ground. The tower is guyed by three lines from the 30-foot level which are spaced 120° apart. Two guy wires approach the ground at 45° and connect directly to anchor pipes which are driven into the ground. The third guy wire runs horizontally for about 50 feet to a pulley, and then down to a winch used to permit foldover and erection of the tower. That guy is insulated from ground by the tree. The whole system is excited from the balun output which connects to the tower and quarter-wave horizontal wire at the 50-foot level.

Pattern runs were made with the horizontal wire pointed in three directions from north: 27°, 98.5°, and 220°. There was no suitable tie point to have a direction in the fourth quadrant.

After massaging the raw data with the attenuation factor, it was plotted and is shown in Fig. 3.

The plots of all three curves on one sheet indicate that there is really not much effort in positioning the horizontal wire in different directions. That result is in contradiction to my previous experience. The only explanation that occurs to me is that the profusion of guy wires has already established a radiation pattern and the effect of the single wire is negligible. With that tower, a quarter-wave wire in any direction is satisfactory.

W2LL Antenna Measurements—Tower 2

Fortunately, I have a second tower, which is free-standing, no guy wires, and has a TH6DXX tribander at the 50-foot level. Runs were made on that antenna with the horizontal wire at 51°, 119°, and 212°. A plot of the radiation runs on the second tower are shown in Fig. 4.

A change in directivity

definitely can be noted although a skewing effect can be seen; the lobes are not in direct line with the quarter-wave wire direction.

Finally, three horizontal wires were connected together using the above directions for each. The effect was to compress the maximum excursions of the individual patterns. The results using the horizontal wire pointing in the 212° direction give the best overall results and was the final selection. There is nothing to be gained by switching from one wire to another to give controlled directivity; the 212° position is the best in all directions.

One thing not expected was the lack of distinct directivity along the 119° direction. I have no explanation except to point out that the first tower was used as the support for the 119° horizontal wire direction. Also, the distance between the two towers is 130 feet! There unquestionably is an interaction between the two towers.

With a free-standing tower, erected far from interfering bodies, a definite advantage may be derived by switching separate horizontal wires for controlled directivity. You must determine that yourself experimentally. I would be very interested in hearing from someone with that situation.

Conclusions

OK, what have I accomplished by doing all this? Let me list what can be concluded *for my setup*.

(1) I had a lot of fun learning about my antennas.

(2) The Zepp is putting a major lobe into the northeast.

(3) Unusual terrain causes drastic pattern changes to the Zepp pattern.

(4) The 60-foot number 1 tower has a non-programmable radiation pattern. Isolation of the guys from the tower with insulators would probably alleviate that characteristic. It is still a pileup buster as is!

(5) The 50-foot number 2 tower is programmable by switching in horizontal wires pointing in different directions. However, in my case, why bother? A wire in the 212° direction is best of all.

(6) There appears to be definite cross-talk between the two towers.

(7) Tying in two or more horizontal wires will tend to make the pattern omnidirectional, but at the expense of stronger lobes.

These tests have shown me graphically the difference between classical radiation patterns and what I am actually getting. Variations in the terrain surrounding the antenna and the interference of large metal structures are two things which have disrupted ideal conditions. Now I know what is happening and don't have that nagging doubt in my mind, "Where is the signal going?" Do you know where yours is going?■

Cheap Scanning for the IC-701

Here's a device that's stingy in cost but generous in benefits.

James R. Harden AG9D
129 Harborwoods Circle
Clearwater FL 33519

You don't have to be stingy, as I am, to build The Scotchman. If you own a radio that will work with Icom's RM-2 but you can't justify the cost, this may be for you. In my own case, I didn't need all the features of the RM-2. All I really wanted was a machine to scan my IC-701 around the frequency where a scheduled contact would be. As the project evolved, I learned that for another couple of bucks, and with the addition of a manual switch, the machine will start any place I choose and scan up or down until stopped.

Many projects tell you to hold down the cost by going to your junk box. If yours has what you need, fine. Mine never does. Almost everything I used was new from Radio Shack. You can include all the options, use a prettier box, go top dollar all the way, and still get by for less than $35 plus tax.

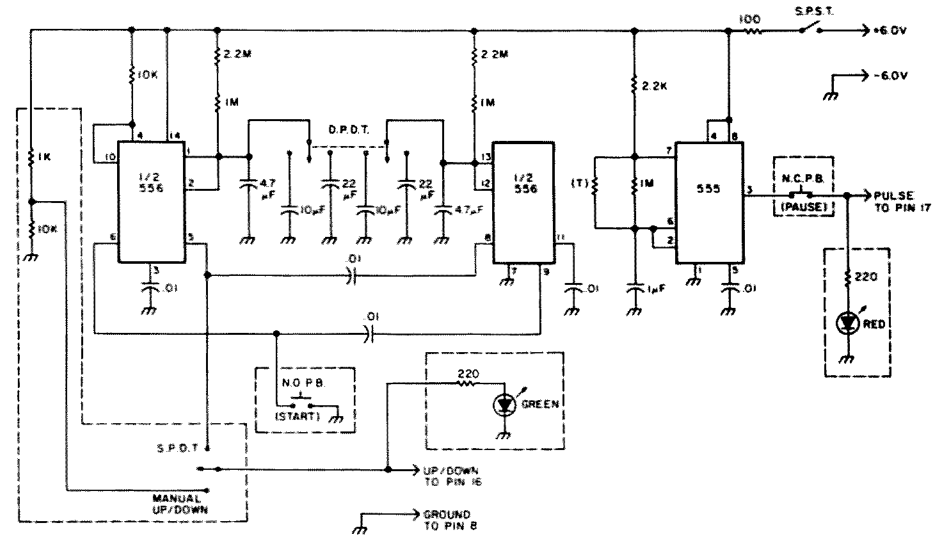

Fig. 1. Schematic diagram. Components inside dotted lines are optional features. If optional components are omitted the unit will work, but with less control.

How It Works

An inspection of the book that comes with the 701, 245, or 211 will show that a pulse applied to pin 17 of the accessory socket will step the frequency one unit either way. The direction it steps is determined by voltage or no voltage (microprocessor logic high or low) on pin 16. Pins 16 and 17 are referenced to ground on pin 8. The book warns: "Care should be taken not to apply voltages other than −0.5 V to +5.0 V to terminals between no. 14 and no. 24, as they are connected to the CMOS IC." It's written in Japanese-style English, but the message comes through loud and clear! Keep the voltage low!

I want to thank Robert Johnson W9TKR for sending pinout information on the Icom 245 and 211.

These units do use pins 16 and 17 for frequency control. Other Icoms may bring connection to the CMOS IC out to a different place.

The simplest pulse generator I know is a 555 IC working in the astable mode. With two external resistors and two capacitors, a 555 will generate regularly-spaced pulses as long as voltage is applied. L. B. Cebik W4RNL wrote a very good explanation of how the 555 series of ICs work in the September, 1980, *QST*.

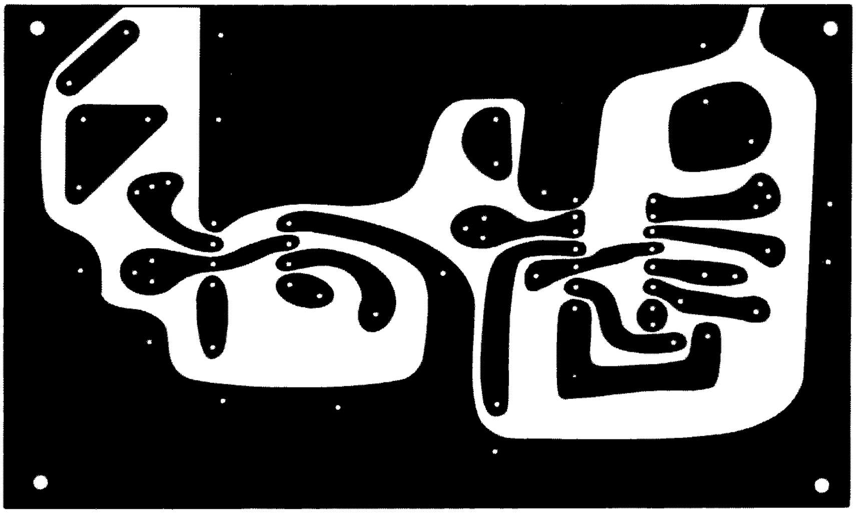

Fig. 2. Printed circuit board (foil side).

The values of resistance and capacitance I used with the 555 give pulses at approximately 1 Hz. I put a tailoring resistor in parallel with the one-megohm resistor between pins 6 and 7. You may find a single resistor that will give the right pulse rate, or you could use a potentiometer. By tailoring, I got a pulse rate of about 1.2 Hz. This is fast enough to cover the band in a reasonable time. It's still slow enough for a few clear words to come through as the radio scans across each station. I can recognize a voice or identify a callsign.

The up/down function is controlled automatically by a 556 IC. The 556 is two 555s in one case. The two timers are operated in the monostable mode and connected so that each starts the other. If equal values of resistance and capacitance are used in each timer, the on and off times at pin 5 will be close to equal. I wanted to be able to vary sweep time by changing resistance, but I couldn't make it work. Selecting capacitance with the double-pole, double-throw, center-off switch gives the three different sweep times.

Optional Features

The first two options give additional control. A normally closed push-button in the pulse line works as a pause control. I use it when I want to hear a bit more of a station or when the scan goes too far in one direction. A normally open push-button between pin 6 of the 556 and ground gives a positive start and control of beginning sweep direction.

A third option is the manual up/down control. It is a two-resistor voltage divider and a single-pole, double-throw, center-off switch. Voltage from the divider is connected to one switch terminal for a logic high.

Side view shows battery case cemented to underside of front panel. Places where I cut foil with a file to make connector pads for LEDs and resistors can be seen.

Center off gives logic low. The other terminal connects pin 5 of the 556 for automatic operation.

The last options are the red and green LEDs. They monitor operation and let you check the unit without it being connected to your radio.

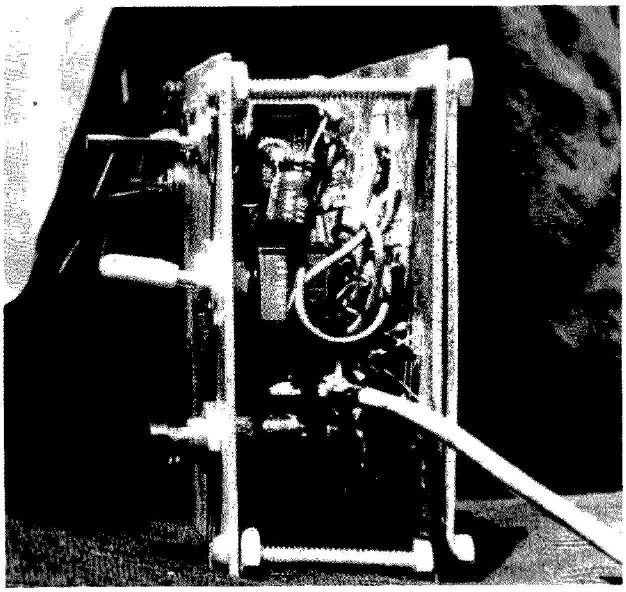
Power Supply

To power the unit, there are several ways you can go. If you elect to build an ac supply, I think you should use a voltage regulator. You could get power from pin 2 of the accessory socket, but it's +13.5 V and you'd have to divide it down and still use a regulator. Remember that +5.0-V limit! For mine, I preferred a battery supply. Batteries never go high. Four AA cells, in a holder glued to the underside of the front panel, do very well.

Construction

Since there isn't any critical circuitry, use any construction method you like. If you use the printed board layout, there is only room for the smallest capacitor pair in the up/down timers. The others must be mounted on the switch.

I used an unconventional packaging method. The one thing I do have in my junk box is lots of single-sided copperclad board. I cut three pieces 3" × 5". I drilled mounting holes in the corners and then etched one for the circuit board. I drilled another for the front panel and used the last under the circuit board as an insulator. It would have been prettier if I'd used just one board and a nice box. My unconventional method does give a low profile and it saved a couple of dollars. I'm stingy, remember? ■



End view of the unit shows details of my unconventional packaging method. The timing capacitor mounted on the switch is visible.

VHF-DX ACTIVITY

Lauro PY3BZM is located in the city of Sao Sebastiao do Cai in Rio Grande do Sul State, South Brazil. He is listening almost every day on 144.3 MHz SSB or FM from 2300 to 0200 UTC, trying for QSOs with Central and North America. Lauro uses a Yaesu FTV-901 transverter with a Brazilian Mac VS 100 linear amplifier excited by an FT-902 DM transceiver. The antenna is a 15-element yagi polarized on 45 degrees.

Lauro has already worked FM7CS, J88AR, J73CS, and J73PD and received all of their QSL cards, except from J73CS. Remy FM7CS used only 3 Watts and a 2 × 9 element beam. Robert J88AR also used low power, 10 Watts, and a 2 × 12 element antenna.

The distances Lauro worked are: J73PD, Roseau, Dominica Island—5108 km; FM7CS, Fort de France, Martinica—5015 km, and J88AR, Kingstown, St. Vincent Windward Islands—4862 km.

For skeds, please contact Lauro Muller PY3BZM, Rua Tiradentes 978, 95760 Sao Sebastiao do Cai, RS, Brazil.

CW GROUP

On October 7, 1982, a few of the CW operators in the city of Santo Andre, an important industrial city in the State of Sao Paulo, established the CW Group of Santo Andre (CWSA). First elected president: Marcos Andre PY2NBI, vice-president: Clovis Crauchi PY2ORW, members of the directory: Alfredo PY2WUK, Ikeda PY2NG, Clovis PY2IBE, Luiz PY2FK, and Oity PY2TNX. They will sponsor the CWSA Award, rules for which we will publish soon.

GCWA AWARD

Sponsored by the Araras Group of CW, the GCWA Award is available to all licensed amateurs for confirmed contacts with 15 different PY2 stations and 3 GCWA members.

Contacts must have been made after January 19, 1981, on any amateur band. Only two-way CW mode. Send to the address below, GCR log of stations worked (call, date, time, band, mode, and report), your personal QSL, copy of the GCWA member's QSL, and 15 IRCs for mailing expenses. There are no special endorsements for the GCWA Award. SWL: Same rules. Apply to GCWA Award, PO Box 15, 13600 Araras, SP, Brazil.

GCWA 60 AWARD

Available to the amateur or SWL who has obtained the GCWA Award and has contacted 60 PY2 stations and 3 other GCWA members. Send GCR log of stations worked (call, date, time, band, mode, and report), your personal QSL, copy of the GCWA member's QSL, and 15 IRCs for mailing expenses to the same address as above.

There are no special endorsements for the GCWA 60 Award. GCWA members: PY1BGJ, PY1BVY, PY1CC, PY1DFF, PY1EWN, PY2AAU, PY2CMS, PY2DCP, PY2DHP, PY2DV, PY2GMN, PY2GOT, PY2IBD, PY2IBN, PY2JN, PY2VFY, PY2XIO, PY2WR, PY2RFC, PY2OIN, PY2IER, PY2ORF, PY2OIL, PY4CAX, PY5CL, PY5FI, PP5WUO.

CANADA

Cary Honeywell VE3ARS
PO Box 2610, Station D
Ottawa, Ontario
Canada K1P 5W7

Just over two years ago, Canadian amateurs had the opportunity of advising the Canadian Department of Communications in Ottawa on the matter of TRC24. TRC24 is the designation for a circular put out by the DOC which details the requirements for the amateur license. Examinations for the amateur license are based on TRC24. The Canadian Amateur Radio Federation (CARF), with the assistance of other organizations, undertook to represent amateurs in these discussions.

Under the direction of W. J. (Bill) Wilson VE3NR, former Director General of the Telecommunications Regulatory Branch, the Federation studied the old requirements and came up with a proposal that seemed to fulfill the needs of the DOC and would ease the burden on prospective amateurs. This proposal was the result of many discussions with DOC officials and comments received from amateurs across the country as part of the CARF National Symposiums.

The outlook for amateur radio was very positive. Favorable comments on the amateur effort were received by the Federation from DOC officials, and letters of appreciation were received from many Canadian amateur instructors who had followed the events as they were reported in *TCA* (*The Canadian Amateur* magazine). Our optimism was short-lived.

Several weeks ago, the new draft of TRC24 was unveiled by DOC. With shock and dismay, amateurs learned that despite all the effort that was put into the amateur proposal and despite the enthusiasm by DOC officials that greeted the effort, not one item of an amateur proposal was used. Needless to say, the Federation pursued the matter with the men in charge, but at this writing, no one as yet knows what happened.

From conversations with Bill Wilson and A. P. (Art) Stark VE3ZS, the two men most responsible for the amateur submission, and after having examined all the correspondence between DOC and the Federation on the matter, I discovered one interesting thing: Almost all of the DOC personnel who had participated in the discussions with CARF had been either transferred or retired before TRC24 was formulated. It almost seems as though the amateurs were forgotten in the rush to leave. It might be noted that TRC24 was circulated just prior to the government's fiscal end-of-year, and this leads me to conclude that someone was anxious to use up a budget before the money was lost and took any old copy of TRC24 that they could find or make up for printing. Prior to this, DOC had informed a CARF official that there were few funds in the budget to do this.

Recently, CARF took this matter up with the new Director General who indicated that he was unaware of the problem but would look into it. As he only recently attained his position in DOC, it was not expected that he would appreciate the efforts that amateurs put into the submissions. However, CARF officials were pleasantly surprised to find that he was indeed interested in determining what had transpired and why the efforts of both amateurs and government officials had resulted in such a debacle. We are confident that a solution will be found.

In the May issue of *73*, mention was made of the question of Canadian amateur participation in examinations. The response to this question was far from favorable. The majority of letters I received (as editor of *TCA*) indicated that the exams were best left to the DOC. Some amateurs suggested that since the quality of the code sending was so poor as to result in only a 50% pass rate, amateurs should be permitted to participate in the code portion alone. Comments are still coming in.

Speaking of *TCA*, some of you may not know that Canada has its own amateur radio magazine. *The Canadian Amateur* celebrated its tenth anniversary in January of this year with a special issue devoted to the history of the magazine. Sponsored by CARF, *TCA* caters to the Canadian amateur with stories and news items that have a Canadian flair. It is not in competition with magazines like *73* as it is obtained only through membership in CARF. Information about CARF can be obtained by writing to The Canadian Amateur Radio Federation, PO Box 356, Kingston, Ontario, Canada K7L 4W2, or by calling (613)-544-6161.

FRANCE

Claude Guee F1DGY
11 Rue Emile Labiche
28100 Dreux, France

REGULATION

In 1983, the French administration (PTT) began using a new amateur examination. Nevertheless, the license characteristics are unchanged: F1—(codeless) radiotelephony for frequencies above 144 MHz, and F6—radiotelephony and radiotelegraphy for all frequencies allowed (F8, 9, 2, 3, 5 are the former F6).

Instead of taking the examination at home or at a radio club, the candidate has to go to one of the nine centers (except for handicapped or 65-year-old persons). Two or three sessions are scheduled for this year. The exam consists of the following parts:

Radiotelephony. (A) procedure, regulations—10 questions; (B) technical—30 questions. The score in (A) must be at least 15/30 points, in (B) at least 36/90 points, and in (A + B), 60/120 points.

No answer gives 0 points, a right answer scores 3 points, and a wrong answer scores −1 point.

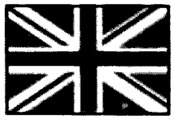
This type of examination (audio-visual) is also used for driving licenses.

Radiotelegraphy. 10 words/minute—26 letters, 10 numbers, 8 signs, and 40 Q-signals. The examination is done in three parts: 30 groups (5 letters, numbers, signs), 30 words in text, and a test on Q-signals.

According to the administration, 50% of the candidates succeed.

ARIANE STORY

According to the official commission of investigation created after the last failure (September 10th, 1982), a lubrication defect in the gear of the turbo-pump feeding the cryogenic motor was responsible for the plummet into the Atlantic.



GIBRALTAR

Jimmy Bruzon ZB2BL
27/2 Flat Bastion Road
Gibraltar

AMATEUR RADIO IN GIBRALTAR

I am sure many of you have, at one time or another, worked Gibraltar. However, on numerous occasions I have come across some amateurs on the HF bands who have returned my call with "It's the first time I've worked a ZB2 after 25 years of hamming."

Gibraltar, with a population of about 30,000 inhabitants, all living within an area of two and a quarter square miles, has only a handful of active amateurs. At present, the most active stations are ZB2EO, ZB2GR, ZB2HM, ZB2HO, ZB2J, and ZB2HC. They are active on the HF bands most evenings, but there are a number of others like myself who don't show up so frequently. In future columns I will be including more information on the operating habits of all the ZB2s, as I am sure it will be welcome, especially by those of you who have not as yet worked The Rock.

Licensing requirements in Gibraltar are similar to those of the United Kingdom with some minor modifications, the most upsetting one being the non-existence of a Class-B license. This means that to obtain an amateur radio license one has to pass the City and Guild's Radio Amateurs Examination and the CW test before applying. We do, however, enjoy the privilege of being able to operate on the 50-MHz and 70-MHz amateur bands.

As far as reciprocal licensing is concerned, this is quite simple; any amateur whose country has reciprocal licensing arrangements with the UK can apply for a reciprocal license in Gibraltar. The callsign issued usually consists of the home call/ZB2. This form of license, known as a temporary license, is issued free of charge. Applications for amateur radio

licenses should be made to The Wireless Officer, Post Office, 104 Main Street, Gibraltar.

Quite often we hear from amateurs wanting to come over and do some operating from Gib. There are a number of hotels quite willing to allow you to hoist up antennas on the roof, and I will be providing more detailed information in the future. However, bear in mind that The Rock is a very efficient rf screen, so if the idea is to be able to work west into the US, a hotel on the *west* side of The Rock must be chosen, and the same rules apply when you want to work toward the *east*.

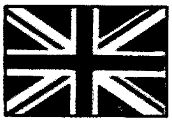
Omnidirectional coverage is very difficult to achieve unless one is willing to sit and operate from the top of The Rock, and that is one thing I would not recommend. Previous experience has proved that it is far easier to create a pileup whilst operating from either the eastern or western sides of Gibraltar than doing it from the top. Apparently the fact that The Rock is a very poor conductor seems to be the cause of the very poor results which have been experienced on various occasions when operating from its top. However, the fact that ground-place antennas have also been tried seems to dispel this assumption.

In the not too distant future, a group of ZB2s will be setting up a station on the top. The exact date has yet to be decided, but I will be giving you information on the event well in advance so that those stations who have not yet worked Gibraltar get the chance to do so, and certificate hunters will get the chance to obtain the ZB2BU Award.

The ZB2BU Award and the ZB2 Award are issued by the Gibraltar Amateur Radio Society, and both awards are available to hams and SWLs. To obtain the ZB2BU Award, all that is required is a log copy proving that ZB2BU has been worked on three different bands. The processing fee is three dollars. The ZB2 Award requirement is proof (log copy) of having worked five different ZB2 stations on any band(s), and the processing fee for this award also is three dollars. Applications should be mailed to The Awards Manager, GARS, PO Box 292, Gibraltar.

Well, that's about all from me for this month. When I write about the operating habits of ZB2s, I will start with Gordon Black ZB2J, who is the oldest licensed resident amateur on The Rock.

73 for now es CU next month.



GREAT BRITAIN

Widnes WA8 9RP
Cheshire, England

THE UK SCENE

Just about every household in the United Kingdom is now within range of 625-line UHF television transmissions (for the four main networks). Nevertheless, the old Band 1 405-line VHF transmissions continue although notice has been given that these will be phased out over the next few years.

The continued use of frequencies in Band 1 for television has been the main reason for the lack of any 50-MHz (6-meter) allocation in the UK. (It should be noted that 50 MHz is not an ITU-allocated amateur band in IARU Region 1.)

The imminent demise of 405-line VHF TV transmissions has not escaped the RSGB (Radio Society of Great Britain) which has been pressing the Home Office (the regulatory authority) for an allocation. The RSGB has been keen to point out that 50 MHz is an important region of the radio spectrum where there is much work to be done in relation to propagation.

The first breakthrough came when the Home Office licensed a beacon in the 6-meter band although operation was initially confined to hours outside those of television broadcasting. This has recently been changed to 24-hour operation. The beacon, callsign GB3SIX, is located on the Isle of Anglesey in North Wales and transmits 100 W erp on 50.020 MHz. GB3SIX beams westward (290°) towards the US, and recent reception reports have included one from Hartford, Connecticut.

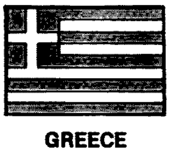
The early part of 1983 saw a much more important breakthrough for UK 6-meter operation when the Home Office agreed to issue forty special research licenses for 50 MHz. Anticipating a great deal of interest, the RSGB invited applications for these licenses and, of some 200 initial enquirers, a few over 100 completed application forms. The lucky 40 were chosen by the Home Office to give a good geographic spread. All UK prefixes are represented in the forty and all holders have Class-A licenses which provide for the CW working. Transmissions may take place only outside television broadcasting hours (which are approximately 0600-0900 and 1200-2400 local time).

During television broadcasting hours or to make a 6-meter contact with another UK ham still requires a crossband (28-MHz/50-MHz) QSO.

Needless to say, our Oriental colleagues have not been slow to spot another chance to increase their UK profits. At the time of writing, the RSGB magazine, *Radio Communication*, contains advertisements for a 6-meter option on the FT-726 and for a self-contained 6-meter rig, the FT-690R. This latter is not described in detail but presumably is a close relative of the multimode 2m and 70-cm rigs, the FT-290 and the FT-790, respectively.

The chance of any home-grown commercial rigs for 6m (or any other, for that matter) are so close to zero as to make no difference. Jaybeam has at least produced a 2-element 6m antenna for vertical or horizontal mounting. Some other 6m enthusiasts have already turned their minds to antennas. Discussions have taken place between G4BPY AND G4GLT on the feasibility of stacking yagis and even of producing a 6 over 6.

Although quite restricted at the moment, the 6m licenses represent a major step forward for UK amateurs, and the RSGB is to be congratulated for its efforts in securing the concession. It is to be hoped that the band will be made available for wider use within a very short time.



GREECE

Manos Darkadakis SV1IW
Box 3751
Athens, Greece

At the beginning of this column, I would like to thank the editors of *73* for their idea of bringing news from amateurs all over the world to the readers of the magazine.

First of all, let's make a short flashback to Greek amateur radio history, which started out in 1958. There was some radio activity before then, but not on a constant basis. A few Greek people and some British were operating from 1933 up to 1948, except during World War II, of course.

In 1958, there was some recognition from the Greek government of the amateur service, and the Radio Amateur Association of Greece was born. After that, people interested in getting an amateur radio operator license were taking examinations at RAAG headquarters; if they passed (not so easy as it sounds), they were rewarded with a conditional license. I use the term "conditional" because at that time there was no law covering the amateur radio service and the government could recall the license at any time and for any reason.

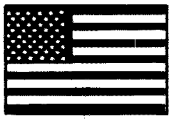
Because of this situation, Greece had only about 200 licensed radio operators up to 1967.

In 1967, with the dictatorship in power, this licensing procedure stopped. A law was made for radio amateurs in 1972 but did not become effective until 1974, just after the end of dictatorship in Greece. From then on, the way was wide open to everybody.

Examinations established by the Ministry of Post and Telecommunications take place twice per year on a regular basis. Today, the Greek amateur population consists of 500 amateurs, and anybody can consider this a big difference. A lot of things have changed from the time that a few pioneers started back in 1933.

Finally, RAAG's latest goal was to obtain the privilege of mobile operation, which was not permitted until 1980. It took about 5 years for the law to be changed so that radio operators could use their gear from cars, boats, etc.

In my next column, we will talk about the Greek amateur community itself and its organization.



GUAM

James T. Pogue KH2AR
68 Banyan Circle
FPO San Francisco 96630

THE VIEW FROM GUAM

Guam's hams and would-be hams have cause to celebrate! Amateur as well as commercial radio exams will once again be offered here on a regular and continuing basis. No exams have been given on Guam since June, 1982.

Prior to this time, the Guam Civil Service Commission had done all radio license testing on behalf of the FCC, mailing completed exams, code tests, and all other information back to the Honolulu District Office for scoring. Turnaround time for this procedure was quite good, and everyone seemed pleased.

In early 1982, however, the Commission announced that due to budgetary cutbacks they would no longer be able to offer radio examinations here on Guam. Anyone who wished to obtain an amateur license of the Technician class or higher, or any of the commercial licenses, would have to travel to Honolulu for testing.

When this announcement was made, several island hams approached Rear Admiral Bruce DeMars, Commander Naval Forces Marianas, and requested that he look into the possibility of having the Navy administer exams for the FCC at no charge. The approval for this arrangement finally came through in early April, 1983. Marianas Amateur Radio Club (MARC) President Dave Chartier W1YRM announced that exams will most likely be given on a quarterly basis as before, but will now be administered by representatives from the Naval Communications Area Master Station (NAVCAMS) here on Guam.

MARC has a supply of FCC form 610 applications for amateur licenses as well as form 756 applications for commercial radiotelephone and radiotelegraph licenses. Forms may be obtained by writing to Marianas Amateur Radio Club, PO Box 445, Agana GU 96910, and enclosing either a self-addressed stamped envelope or self-addressed envelope with sufficient IRCs to cover return postage.

When the applicant completes the appropriate form, he should send it to the FCC, PO Box 50023, Honolulu HI 96850. The FCC then will inform the applicant when and where the test will be given here on Guam. Advance notice of at least one month will be given prior to scheduling of test dates.

After the tests are scored in Honolulu, applicants will be notified by mail as to whether they passed or failed. Applicants who pass will have their paperwork forwarded to FCC headquarters for issuance of the appropriate license.

All of us who are either anxious to upgrade or get our first license owe a note of thanks to the Navy and those amateurs who worked to get approval of this system.

ISRAEL

Ron Gang 4Z4MK
Kibbutz Urim
Negev Mobile Post Office
85530 Israel

In June, I briefly outlined the Israeli amateur scene and licensing structure. In this month's column, I'd like to sketch out how a typical amateur here goes about getting on the air and in this way give you some of the flavor of ham life in our country.

Our typical amateur started out while still in high school, finding out about the hobby either from friends or a notice advertising an amateur radio course. The course is either at a high school, community center, or local radio club. (Community centers in Israel offer a wide variety of activities ranging from arts and crafts and folk dancing to computers, and some of them also have a club station with a ham on staff part-time to supervise it.)

4X4HQ, for instance, the Tel Aviv Youth Center's club, has turned out scores of licensed amateurs over the past years. While learning the code and theory, the newcomer can get a taste of what's on the bands by operating the club station, under watchful supervision, of course.

Well, he or she has finally passed the Novice test and is now faced with the task of assembling a station on a meager high-school student's budget. Thankfully, there is no shortage of surplus equipment available (one of the very few advantages of living in a country with a high defense budget). Some of this gear finds its way to junk dealers where ham scouts snooping around are quick to let out the word on the two-meter grapevine. Other items are sometimes donated directly to the Israel Amateur Radio Club. Such was the case last year with forty-four excellent circa 1960 Siemens tube-type general-coverage communications receivers retired from government service. Interested IARC

members mailed postcards to the club, a draw was held, and for a nominal donation to the club's treasury, the winners became the owners of these beautiful boat anchors.

Now, the first transmitter is almost always home-brew, crystal-controlled, built from scrounged parts, reminiscent of what American Novices were putting together in the fifties and sixties. The schematic diagram must be on file with the Communications Ministry, as all transmitters must be authorized and registered. In Israel, it is a criminal offense to be in possession of unlicensed transmitting equipment.

And what is the scope of our Novice's on-the-air activity? After putting up some kind of simple antenna, our new ham begins his DXing on 15-meter CW and works the local gang on 40 meters on Saturdays, our Sabbath. But few Novices are satisfied with these limitations after the novelty has worn off, and with the radio club's help they go for the Grade-B license for the use of all bands and modes.

By this stage, few amateurs will still be working with home-brew gear. I must point out that customs duties on ham gear in Israel are quite reasonable, so that Japanese transceivers sell here for slightly under US list prices. And this is in a country with 100-to-200-percent duty on automobiles, electrical appliances, and television receivers. So it's not rare to hear fellows with the latest Kenwood rigs who don't own their own car. But then, we must keep our priorities straight!

There's a lot of used gear for sale ranging from older tube-type transceivers to fairly recent solid-state rigs, again with prices comparable to those stateside. At present, there's only one outfit dealing in new ham gear, but they seem to be doing a rip-roaring business.

The Grade-B licensee will no doubt also get on the very popular two-meter band, using the five national repeaters with a wide variety of equipment—but more about that in a future column when we'll delve into the VHF scene here.

I hope that you don't get the idea that all beginning hams here are youngsters, but a great many indeed are. Recently, the Holon-Bat Yam (a southern suburb of Tel Aviv) Club started a course especially for adults who found it emotionally difficult to be studying with a group of kids. However, I know of adults who studied along with younger enthusiasts without any hang-ups.

Just recently, a correspondence course for the Novice-class ticket was put out by the "Open University," a government-aided post-secondary institution, and they are reported to have a Grade-B course in the works. Hopefully, their books will soon be available over the counter, and at long last, literature in the Hebrew language will be available for aspiring radio hams.

An interesting statistic is that in the last five years, over 250 new licenses have been issued, this being roughly one-quarter of the total Israeli amateur population. There can be no mistake about it—ham radio is definitely on the upswing here!

AWARDS FROM ISRAEL

The Israel Amateur Radio Club has two certificates available. The first is the veteran 4 × 4 = 16 Award and is valid for all contacts with Israeli stations since 1948. You need a total of sixteen contacts on at least four different bands in any mode.

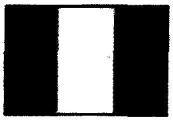
The second certificate is the new Israeli Award. This is valid only for contacts made after January 1, 1982. Twenty-five points are required—contacts on frequencies lower than 10 MHz are worth two points and on other bands are worth one point, while VHF and UHF contacts are worth ten points.

For either of these two awards, send one dollar or four IRCs plus a fully detailed log of the contacts certified by another licensed amateur to: Awards Manager, Israel Amateur Radio Club, POB 4099, Tel Aviv, 61040, Israel.

The Jerusalem amateurs have just recently made available the Jerusalem Award. You need five contacts with Jerusalem stations dating from January 1, 1983, on any bands or modes, crossmode acceptable. Here QSLs are necessary, and along with them send ten IRCs to the award custodian: Dr. Milt Gordon 4X6AA, POB 4079, Jerusalem, Israel.

All the above awards also are available to shortwave listeners under the same conditions as to hams.

Well, that wraps it up for this month. I'll be happy to relate any areas of the Israeli amateur scene that may interest you in this column, so don't hesitate to drop me a line. Till next month, *73* and shalom.



ITALY

Dr. Giancarlo "Chas" Martelli I0XXR
18, Via Bevignani
00162 Roma, Italy

Italian amateurs are not yet permitted to use the new WARC bands, including 160 meters. The WARC Acts were ratified with a presidential law dated July 27, 1981, and it stated that the WARC 79 Acts should become effective in Italy on February 1, 1983.

Despite that, and in open contrast, the Ministero delle Poste, with its own edict, issued the new Italian band plan which does not consider the new WARC bands, including the 160-meter band, and does not mention the UHF bands above 24 GHz.

The band plan, which was issued without previous consultation with the Associazionne Radioamatori Italiani (ARI), is filled with errors and discrepancies with respect to the WARC allocations confirmed on the other side by an official law of the republic. One of the funniest topics is the statement that in case of natural disasters, the Ministero delle Poste reserves use of the 144-146-MHz band for "its own *international relief* communications."

This gives only a pale idea of the situation of the Italian administrative bureaucracy, completely out of tune with the real necessities of an advanced society. It misunderstands the specialized and technical problems in any field due to the lack of capable and specialized personnel and due to the chronic laziness of the office workers.

I think that the ARI is presently making some progress toward overcoming the situation, but there are not many hopes for a fast resolution to the problem.

Diploma Anno Santo
(Holy Year Award)

This award will be issued by the ARI, Sezione di Roma, PO Box 361, 00100 Roma, Italy. It will celebrate the Extraordinary Jubilee, 1983. The requirements are, for Europe: 15 QSOs, any band, any mode, with stations in Rome, or 10 QSOs with Rome stations and one QSO with a station in Vatican City; for other continents, 10 QSOs, or 7 and 1, respectively. The same stations can be worked only once per band.

The award period: March 25, 1983, to April 30, 1984. Send logs certified by officials of your association (or two other amateurs) with your application and US $8.00 or 20 IRCs.

The award is 18 × 13 inches, beautifully printed in six colors on deluxe paper, and represents engraved copper artwork of the St. Peter Basilica. The same artwork is used on the special QSL which will be used mostly by the radio amateurs of Rome in the course of the Holy Year.

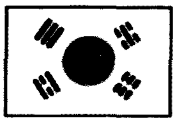
The St. Peter engraving and the layout of the award is by an artist in Rome who is also a radio amateur—I0EBR.

New Italian Prefix

The Italian Ministero delle Poste e Telecomunicazioni has recently started to assign IK to the prefix of all new licensees. The callsign combinations restarted with AAA for all IK-prefix licenses.

The IW prefix is for special licenses with permission to operate to 28 MHz. These are no-code licenses. Different prefixes are assigned to the residents in the so-called "special statute regions." These regions have their own parliament which institutes minor laws with regard to particular local administrative and economic problems. Sardinia has an IS0 prefix and Sicily has an IT9. Other special statute regions and their prefixes include: Valle d'Aosta—IX1, Trentino Alto Adige—IN3, and Friuli Venezia Giulia—IV3.

Other prefixes are assigned to the Italian islands:
Ligure Archipelagus—IA1
Tuscan Archipelagus—IA5
Ponziane Islands—IB0
Napoli Islands—IC8
Eolie Archipelagus—ID9
Ustica Island—IE9
Egadi Archipelagus—IF9
Pelagie Archipelagus—IF9 (Zone 33)
Pantelleria Island—IH9 (Zone 33)
Cheradi Islands—IJ7
Tremiti Islands—IL7
Minor Sardinian Islands—IM0



KOREA

J. Michael Wengert HL9KT/KH2AC
CPO Box 2961
Seoul, Korea

The Korean Amateur Radio League President, Mr. Min-sup Lee, is now on the air with his newly acquired callsign, HL1AOT. Mr. Lee is the first Korean National Assemblyman to hold an amateur radio license and to operate on ham bands. Unlike US Senator Barry Goldwater or the Japanese Dietman who also are legislator/hams, Mr. Lee became a radio amateur after being elected to public office. In fact, Mr. Lee was elected KARL president even before he was licensed. He holds the Radiotelephone Class license and is expected to operate SSB in the 3.5-, 7-, 21-, and 28-MHz bands as well as 144-MHz FM. He operates Korean-made equipment. A welcome to HL1AOT to ham radio and to his second year as president of the Korean Amateur Radio League.

SIARA

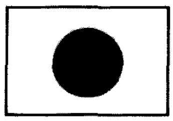
A new organization is being formed, or rather, an old organization is being reactivated, in Korea. It is the Seoul International Amateur Radio Association. SIARA was formed originally in 1978 as a way for hams of various nationalities to get together socially. Later, a club of HL9 operators (US military/civilians) was formed and more or less took the place of SIARA. Now, in 1983, SIARA is being reorganized with the sole purpose of promoting reciprocal operating agreements between Korea and nations of the rest of the world. Our sister organization, TIARA, in Tokyo, proved to be very effective in such a capacity in Japan. Now that the US military authorities have decreed that all HL9 operation will take place only from US military installations, and considering that about 90% of all American hams in Korea live off post, it would seem that such an organization would be useful in getting direct operating permission from the Korean government instead of the US signal authorities. If you are a ham of any nationality residing in Korea or planning to live here, contact SIARA, CPO Box 2961, Seoul, Korea, or telephone 720-6188 and ask for Mike.

* * * * *

A net, composed mostly of members of TIARA (Tokyo International Amateur Radio Association), AARCK (American Amateur Radio Club of Korea), FEARL (Far East Amateur Radio League), and SIARA meets every Sunday. The time for The Far East Net is 0100Z, and frequency is 14.285 MHz. Everybody is welcome, the language is English, and the *Westlink News* tape is aired at 0130Z.

* * * * *

Items of operating news are requested from all HL stations as well as station or club photographs. Send all information to me. That's all for this month. 73 from the Land of the Morning Calm.

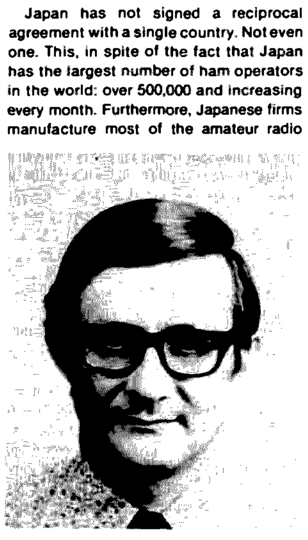


JAPAN

R. E. Waite W9PQN
Tomigaya Grand—301, 2-19-5 Tomigaya
Shibuya-Ku
Tokyo 151, Japan

NO RECIPROCAL LICENSING IN JAPAN YET! WHAT HAPPENED?

Japan has not signed a reciprocal agreement with a single country. Not even one. This, in spite of the fact that Japan has the largest number of ham operators in the world: over 500,000 and increasing every month. Furthermore, Japanese firms manufacture most of the amateur radio



Roy Waite W9PQN.

equipment sold around the world, and by now probably everyone is aware of the superpower status that Japan has attained in the fields of computers, televisions, cameras, radios, audio equipment, etc.

Japanese tourists are most of those travelling in Asia, including Australia, replacing Americans in that latter category. Japanese industry produced more automobiles than did the US last year, and Nippon Steel replaced the United States Steel Corporation as the world's largest producer of steel. (Most Japanese, however, live in small, crowded "rabbit hutches" and do not yet enjoy the "good life," but this is a separate matter.)

But when it comes to a relatively and apparently simple matter like amateur radio reciprocal operating, the score is zero. What happened?

Until 1981, Japanese radio law stipulated that only Japanese nationals could operate ham radio in Japan:

Article 5.
A license for a radio station shall not be granted to a person in any of the following categories:
Paragraph 1.
(1) A person who is not a Japanese national...

On May 15th, 1981, the Japanese upper house of the government passed a new law and added the following paragraph to the existing radio laws of Japan:

Paragraph 2.
The provisions contained in the preceding paragraph shall not apply to the following radio stations:
An Amateur Radio station (a radio station established by an individual for the purpose of conducting radio communications for his personal interest) which is established by an individual who holds citizenship of a country that permits Japanese nationals to establish the same kind of radio station in that country.

So there you have it! Pretty simple, isn't it? There is the legal status for reciprocal operating. It's on the books. It's the law! So all we do now is fire up the rig and go on the air, right? Wrong! Agreements have to be signed with governments of other countries first. Well, all right. Let's sign the agreements. Japanese officials have stated privately that their goal is to sign an agreement with America first. The other countries can wait. Well, all right again. I happen to be an American. I feel sorry for the citizens of other countries, but if Japan wants to sign with America first, I'll go along with that. Why don't we sign? Here it is getting towards the end of 1983 and so far we have nothing. Well, not exactly nothing. Read on.

The Japanese government sent letters to the governments of twelve "prominent" countries around the world, including the United States, outlining the terms of a reciprocal agreement that Japan would like to enter into. Some responses were thereafter received—some good, some not so good. The US response, mercifully, indicated that the US would not accept the Japanese terms. Why do I say "mercifully"? Well, first of all we will have to understand the regulations that presently apply to Japanese applicants to get on the air here in Japan.

After passing the Japanese license examination, if a Japanese person wishes to operate with more than 10 Watts, he has to pay a fee the equivalent of over $100 and wait six months for a government inspection which can be rather strict. Of course, if he is satisfied to stay within the 10-Watt power limitation, he simply applies for that through the JARL, pays his fee, and after permission is granted, he may go on the air without going through the trauma of an inspection. But only 10 Watts.

It is these terms plus some additional red tape that the Japanese government wishes to pass on to the Americans and other foreigners who wish to operate in Japan. This seems to ignore the short-term visitor to Japan. How will he get on the air? Obviously he won't have time to wait for the inspectors to come, so he will have to operate with only 10 Watts. And don't forget the $100-plus fee he has to pay for only a few days of operating.

Another condition the Japanese government wishes to impose on the foreign ham is a requirement that the applicant obtain written permission from the landlord or hotel manager (or whomever) to operate ham radio on the premises. Furthermore, prior application to the government will not be permitted. Application has to be made by the applicant after he arrives in Japan. We are told that an American visitor would be allowed to operate a station owned by a Japanese friend. But what if you don't happen to have a Japanese friend?

Is this reciprocity? Of course not. And it is for that reason that the US has wisely decided to negotiate the matter. But, my friends, the word "negotiate" to a bureaucrat turns on all kinds of happy thoughts, for this is the stuff that justifies their existence. Negotiations take days, months, even years, as we all know. But negotiate we must if we are going to get anywhere.

Another side problem is that 88% of Japan's amateurs are no-code phone-class Novices. How will they fit into the US scheme? The US is considering letting them use the bands above 50 MHz. In Japan, these same Novice no-coders are allowed everything except the 20-meter band, but they are limited to 10 Watts.

Incidentally, the no-code-class hams in Japan are the reason that, for the most part, Japanese amateur radio is more or less an extension of the citizens band, including its numerous abuses, bad manners, overcrowding, and general lack of knowledge of what amateur radio is all about. (Are you listening, America?) But that, too, is another story.

Japan has a long history of xenophobia and it is not surprising that it has taken so long to come this far. Non-Japanese are barred from many activities in Japan. For instance, an American lawyer is strictly forbidden to practice law in Japan, even if he can speak, read, and write Japanese fluently and could pass the bar examination if he were permitted to take it. Conversely, a Japanese lawyer may take the bar examination in any one of the States and freely practice law in the US. Many are doing so.

Discrimination is not illegal in Japan and is freely practiced. It is not unusual, for example, to see an advertisement in the vernacular press promoting a certain product or inviting readers to participate in some sort of promotional contest, with the notation at the bottom of the advertisement, "Japanese nationals only."

In the area of trade, Japanese are often considered to be unpatriotic if they purchase foreign-made goods here. Tobacco dealers (controlled by the government) are not allowed to promote US cigarettes and, in fact, only 30% of the cigarette shops throughout Japan are allowed to sell American cigarettes. (The question of whether smoking is good for you or not is a separate matter. The Japanese government has not yet determined that smoking is hazardous to your health, and cigarette packages carry only a mild warning: "Don't smoke too much.")

The government puts an extremely high tariff on beef and oranges imported from the US, which results in US beef selling at $25 and $30 per pound and oranges at $2 each. These measures are designed to protect the Japanese farmers. In fact, the Japanese have never allowed any product to be imported that would damage Japanese industry or agriculture in any way. An American car costs two times here what it would cost in the US due to taxes and charges added by government regulations. Japan, on the other hand, freely sells automobiles, cameras, computers, television sets, and, of course, ham rigs and whatever else in the US.

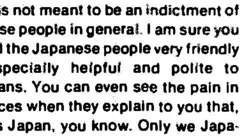
Now back to ham radio. A Japanese ham may take the US test and receive a license and callsign of his very own. In Japan, even if you take and pass the Japanese ham exam (many Americans and other non-Japanese have done so), you will be given an operator's permit but not a callsign. You will have to operate a Japanese club station—but not without first reporting the fact to the government.

Some of the preceding does not seem pertinent to ham radio, but I think it is useful to look at reality instead of viewing Japan through cherry-blossom-colored glasses. So many Americans visit Japan for a few days and seem to come away convinced that everything is fine in Japan, the "great economic miracle." Few would care to live in crowded hovels and pay super-high prices for goods which are kept artificially high by government regulations.

So, with this background information in mind, where Americans are not allowed to participate in society, where all American (all non-Japanese) residents are fingerprinted when they take up residence here (and re-fingerprinted every five years) and required to carry a foreign registration card at all times, and where foreign goods are not welcome, it should not come as a surprise that the Japanese government is reluctant to license foreign hams. There is a tendency for the government of Japan to try to control its residents, and this tendency is even more evident in the case of non-Japanese residents. We often refer to Japan as the country of "over-control."

This is not meant to be an indictment of Japanese people in general. I am sure you will find the Japanese people very friendly and especially helpful and polite to Americans. You can even see the pain in their faces when they explain to you that, "This is Japan, you know. Only we Japanese can get an amateur radio callsign in this country. Sorry."

The JARL, under the able leadership of Shozo Hara JA1AN, has done a lot in attempting to solve the problem and continues to work closely with the Ministry of Posts and Telecommunications. It's possible that a solution will be forthcoming soon. We wish them a lot of luck.



LIBERIA

Brother "Don" Donard, Steffes, C.S.C.
EL2AL/WB8HFY
Brothers of Holy Cross
St. Patrick High School
PO Box 1005
Monrovia, Republic of Liberia

The Liberia Radio Amateur Association is making an all-out effort to help the Ganta Leprosy Control Center which finds itself practically in a state of emergency.

The two-room, mud-walled houses in which the patients live are termite- and rat-infested. The lepers have no feeling in their extremities, and the patients awake in the morning to find that their fingers and feet have been chewed on by the rats. The situation is bad, and Sister Dr. Chambers has made an appeal for help.

H. Walcott Benjamin, president of the Liberia Radio Amateur Association, and S. Richelieu Watkins, assistant minister of Post and Telecommunications of Liberia, have decided to organize the amateurs and put on a worldwide special-event program. The object of this program is to acquaint the outside world with the plight of these unfortunate patients in the hope that help will come. Mr. Watkins has forbidden amateurs in Liberia to request donations, but it is hoped that donations will come.

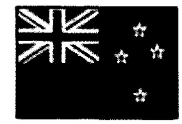
Mr. Benjamin has set up a special QSL manager, Bob SM4CWY, who will handle all the mailing for the project. His address is Box 134, S-67101, Arvika, Sweden.

The association designed a special QSL card with pictures of the leper colony on it. The special event began in May and will continue to December 31, 1983. Any amateur who contacts one of our Liberian amateur stations and sends a QSL card to our manager with a self-addressed envelope and postage coupons will receive the special QSL card. There is a special award if an amateur submits satisfactory evidence of having worked six Liberian counties on any band, with at least two contacts on CW.

Amateurs in Liberia work under severe handicaps. Their numbers are small (less than a hundred) and in some of the counties there may be no operators at all, or just one or two. There is a Liberian Net which meets every day and everyone makes a special effort to check in twice a week. Because of schedule conflicts, it is difficult for all amateurs to check in at the time scheduled for the net.

In spite of these difficulties, Liberian amateurs have distinguished themselves several times by their handling of real emergency situations. It is almost routine for amateurs in outlying areas where there are no doctors or medical facilities to accept medical advice, over the air, from a doctor in the city who very likely is an amateur himself.

If the amateurs in Liberia succeed in substantially helping the Ganta lepers, they will chalk up another victory in their efforts to help their fellow man.



NEW ZEALAND

D. J. (Des) Chapmen ZL2VR
459 Kennedy Road
Napier, New Zealand

In a previous column, I explained the national structure of NZART and this month I shall move on down the line to the branch level of the organization.

There are 80 branches of NZART throughout the country, each branch an autonomous body, affiliated with the national association. Branches have their own finances, club rooms, and assets in the way of amateur radio equipment, test gear, repeater stations, etc. They make their own policies and domestic decisions in most instances, without any reference to the national body. The only decisions

requiring ratification from the national association are those which might conflict with that association's constitution and rules.

The main objectives of the branches are "to further the objects of the NZART, to establish and operate amateur transmitting stations, etc., to foster local interest in amateur radio and associated electronics, and to assist with Civil Defense and emergency communications."

Branches are controlled by a president and a committee elected at the Annual General Meeting each year. Branch activities include the following: participation in the annual National Field Day station operation, the annual Amateur Radio Emergency Corps (AREC) Network Field Day, meeting every month for the purpose of conducting club business, providing technical or nontechnical discussions or lectures, and organizing other activities for the members' interest.

Looking through the "Branch Directory" published in the *NZART Annual Call Book* indicates that most branches have a regular club net, all have a branch callsign, most meet regularly each month, organize or run classes of instruction for prospective radio amateurs and encourage qualified amateurs to advance their respective licenses by further qualifying at CW, and operate a section of the AREC in their areas, and about half of the branches operate and maintain VHF repeaters. A few branches in the larger cities also operate a UHF repeater.

Some branches organize group projects from time to time, and these project kits are made available to branch members at a small cash profit to the branch to assist club finances. In some instances, the project kits are also made available to all NZART members through the national magazine, *Break-In*, or by direct advertising methods to the various branches throughout the country.

Some recent project kits include power supplies, 12-V fixed and variable, RTTY accessories, VHF converters, preamplifiers, instrument cases, small transceivers, and numerous pieces of small ancillary equipment for use in or around the amateur radio station.

Amongst the NZART contests and awards, there is one for working different branches; overseas stations are required to work 35 different branches, and there is a special endorsement if the award is worked within a 12-month period. (The cost is 60 cents NZ, and if you want further information, contact me at the QTH above.) Some individual branches have branch awards, including Auckland, Upper Hutt, Kapiti, Mamawatu, Gisborne, Christchurch, Western Suburbs, Hutt Valley, and Wanganui.

Bits 'n' Pieces

The results of the National Field Day Contest held in February have just come to hand. ZL1RK of the Western Suburbs Branch station was 1st overall, ZL1VK of the Papakura Branch station was 2nd overall, and ZL2ABJ of the Napier Branch station was 3rd overall. Napier ZL2ABJ (Branch 25, NZART), as well as making 3rd place overall, was 1st place in the ZL2 area (see the photo). Because of various problems, there are winners for each of the four ZL districts at each Field Day as well as overall winners for the whole country. ZL1RK also won the ZL1 area contest; the winners of the ZL3 and 4 areas were not available at the time of writing.

New ZL Awards

As part of the NZART activities for World Communications Year, 1983, a Five-Band Worked all Pacific Award will be made available. The requirements are to work 30 eligible countries in the Pacific (e.g., those Oceania countries eligible for WAC as Oceania) on each of 5 different bands, making a total of 150 contacts. QSLs are not required. Send a list of log extracts to the NZART Awards Manager, 152 Lytton Road, Gisborne, New Zealand, with NZ$9.00 for airmail postage and the award, which is on a handsome, suitably-inscribed wooden shield with an NZART badge mounted on it.

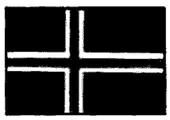
The Napier Branch 25 Group, winners of the ZL2 section of the 1983 National Field Day Contest.

Another new ZL award available this year is the IARU Region III Operating Award. This award is made available to publicize Region III. It is for all licensed amateurs and SWLs. Contacts made after April 5, 1982, are eligible, but certificates will date from January 1, 1983, as part of WCY. QSL cards are not required. Send a certified list of eligible contacts from your log book; the cost is NZ$1.00 surface mail or NZ$2.00 by airmail. The basic award requires 7 countries, the Silver Star endorsement requires 12 countries, and the Gold Star endorsement requires 17 countries. Awards may be endorsed for any mode or band. Eligible countries: Japan, Australia, New Zealand, Korea, Philippines, Hong Kong, New Guinea, Thailand, Singapore, India, Sri Lanka, Tonga, Western Samoa, Soloman Islands, Indonesia, Malaysia, and Fiji. Send your applications to the NZART Awards Manager, 152 Lytton Road, Gisborne, New Zealand.

NZART has a new president, Don Mackay ZL3RW, who has been on the air since 1952 when he started off with an ARC-5 war-surplus transmitter. Don is involved with the electronics industry in Christchurch and has served in many positions in ham radio, both at branch and national levels. He also had a period as editor of *Break-In* from 1970 to 1976. Don is returning to the administrative ranks of NZART after a spell from these duties, and when time permits he is active from 160 through 432 MHz and with mobile activities 80 to 10 and 2 meters.

Our retiring president, Jumbo (Arthur Godfrey ZL1HV) has served the amateur fraternity of New Zealand well. Arthur travelled extensively during his presidency, visiting most branches and attending branch meetings throughout the country. His actions were appreciated by amateurs everywhere, especially those in the smaller centers without any direct representation on the National Council. We all wish him well and hope that the time gained will be put to good use on the ham bands.

Another old-timer making a return to the national scene as a councillor is "Jock" White ZL2GX. Jock is better known to overseas amateurs as the NZART Awards Manager, a position he has held for over 35 years. He has been associated with NZART for some 50 years now and is a life member of the national association and his local branch at Gisborne. He has retired now, so he must have some spare time available to help administer our national organization.



NORWAY

Bjorn-Hugo Ark LA5YJ
Postboks 39, Manglerud
Enebakkveien 208
Oslo 6, Norway

I would like to begin this presentation of ham radio in Norway with the sad news of a great loss to DXing in Norway. Our top DXer, Arne-Sten Gretland LA1KI, left us last autumn only 40 years old. The whole DX fraternity is still stunned with grief. All the great times we had together are still clearly remembered. As president and one of the founders of the LA-DX Group and a member of the board of NRRL and many other associations, he will be remembered for his willingness and eagerness to do everything for everybody. We often wondered: How does he manage time to work DX? A great friend to everyone, may he rest in peace.

LA1KI started what I am here writing about: He joined the whole country in one DX association, an association which now has 76 members and is still growing. 76 members does not sound like a lot, but remember there are only 4000 amateurs in Norway and to be a member you must show proof of having at least 100 counties confirmed. Most have more than 200. Those 76 members together with the Trondheim DX Association are the top DXers and contesters in Norway. You probably have heard them in the pileups.

In the Oslo area, there is a DX frequency on 2 meters, 145.375 MHz FM. You will always find somebody listening on that frequency if you happen to visit Norway. (I will write about reciprocal licensing below.)

The LA-DX Group meets every Sunday at 0900 Norwegian time, on 3750 kHz, to exchange news and information about the happenings on the HF bands. Quite often during wintertime, DX stations check in and we are very pleased indeed.

Actually, some of the comments made after a DXpedition has taken place could give some of the guys on that expedition something to remember till next time. Of course, Europeans are not the easiest lot to handle in a pileup, but the right guy on the frequency can do wonders with the mob. The opposite, which unfortunately happens too often, makes you wonder: Why on earth did I choose DXing as a hobby and not rag chewing? You really just want to give it all up. But, stubborn as only a DXer can be, you stick it out, wait for the moment when the QRM gives in a little, work the station, and go QRT, still wondering why you don't sell the gear.

I will in the future take up this matter and offer some comments about the DXpedition's way of handling the traffic and try to illuminate what really is going on on the frequency. I think quite a few hams not interested in DXing would like to have that explained—why people behave as if they haven't the slightest idea about normal human behavior. Sometimes I really wonder myself.

It's not very easy to start a column! I'm not sure what should be in it, so I'll just have to take a chance and hope somebody will be reading it. I have already mentioned reciprocal licensing, and I can assure you that a license in Norway is not very difficult to obtain. You won't have to wait for an answer too long, either, if you fill the requirements and do as I suggest below.

Norway has reciprocal licensing agreements with the following countries, as per April: Canada, Denmark, England, Finland, France, Iceland, Luxembourg, Spain, Switzerland, Sweden, USA, Germany, Austria, and Holland.

The procedure to be followed by a foreign amateur to obtain temporary permission to operate an amateur radio station in Norway is as follows: The person in question shall prove, by a copy of his license, for example, that he has been registered in his country as a radio amateur.

An application should be made on a special application form, B1.570.3.80, obtainable from the Norwegian Telecommunications Administration. The address is listed below. Do remember an SASE and sufficient IRC postage to cover the way you want the form to be forwarded to you.

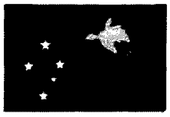
The application should be carefully filled out and sent to the proper licensing administration in the applicant's native country. The administration concerned is requested to give, under "Comments on the Applicant," its opinion on the applicant. The form should then be forwarded to The Norwegian Telecommunications Administration, Radio Inspection Office, PO Box 6701 St. Olavs Plass, Oslo 1, Norway.

A certificate of good conduct, issued by the applicant's local police authority, must be enclosed.

The application should be sent in time to arrive at the headquarters of the Norwegian Telecommunications Administration at least one month before the permission will be required.

A foreign amateur staying permanently will be issued an LAØ callsign, valid for one year at a time. If the stay is less than one year, temporary permission will be issued for three months at a time. The callsign used will be the same as used in the amateur's native country, followed by

. In both cases, a fee of Norwegian kro-
90 must accompany the application.
)perations taking place in the Norwe-
n Arctic or Antarctic are subject to
ecial conditions. Application must be
de separately for such operations.
The license issued to the applicant in
, native country must correspond to a
rwegian Class-A (General) or Class-B
ovice) license. In the latter case, the
efix will be LB0 or the suffix will be /LB.
I hope you will enjoy operation from
orway and make some good friends
re. I wish you good luck and welcome!



The late Arne-Sten LA1KI and Hugo LA5YJ involved in some heavy contesting at LA1KI's. Photo by Jorgen LA5UF, the third participant.

PAPUA NEW GUINEA

iegi Freymadl P29NSF
O Box 165
abaul, Papua New Guinea

Once again, greetings from P29-land to ll amateurs around the world. The New uinea Islands received a lot of "shakes" uring March; one earthquake registering .5 on the Richter scale lasted four ninutes and was followed by dozens of ftershocks. Fortunately, no loss of life nd not too much damage were suffered nd I'm very happy to report that there vas no damage to rig or antennas. That vould have been a real disaster!

Bob P29NBF, in Goroka had a visit from he electronics king of Australia, Dick mith VK2DIK, who was touring Papua lew Guinea with his wife. Goroka was on he itinerary with an overnight stop from '4 March to the 25th. Dick got together vith Bob P29NBF and Margaret P29NUN, ınd he did manage a number of contacts rom Bob's shack. We knew we would ear from Dick again soon as he resumed is "around-the-world helicopter flight" in Aay, setting out for Indonesia and west rom there.

The Annual General Meeting of the Papua New Guinea Amateur Radio Societ y was held in Port Moresby on March 25 ınd a new committee was elected. Amateurs from other provinces had been nvited to come up on the 80-meter net for voting, but apparently no votes were eceived over the air. Bob P29BS was elected president, but has since resigned for health reasons. Peter P29NUK s the secretary and Pat P29NPN is the reasurer.

Trevor P29ZTD is the committee member representing VHF activity. The QSL Bureau remains with Rae P29NYL, who has handled it so efficiently in the past. Col P29NAB is the awards manager, and net controllers for the 80m net are Gordon P29NGG, Brian P29BP, and Peter P29NUK/ ZUK. Also discussed at the meeting was the fact that a monthly column now appears in *73* giving news of the P29 ham scene. Everyone was interested and agreed that it was a good thing to get P29 on the map. With P29BS having resigned the presidency, an extraordinary General Meeting will have to be held. It is hoped that Bob can be persuaded to change his mind. He is a ham of long standing and vast experience and is admirably suited to the task.

Over the Easter weekend we had two amateurs staying with us: Shirley P29SM and her OM, Phil P29PM. Phil has just been allocated a full call; he was P29NPM previously. Shirley and Phil are from the Summer Institute of Linguistics at Ukarumpa. They are spending two months in the East New Britain province and will be erecting buildings in a village a few kilometers from our QTH. The buildings will be used for literary classes in the local language. We had fun with three operators in the shack at times and it was a case of musical microphones rather than musical chairs! We were able to oblige a number of VK stations and a VS6 with contacts for the Bird of Paradise Award. Phil and Shirley spent 12 months in the United States some years back, and while there, Shirley attended a ham cram course which enabled her to obtain her full call.

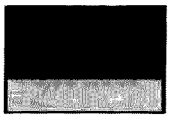
The Western Province of Papua New Guinea should be fairly well represented on the amateur bands soon, with operations going ahead at the OK Tedi Mine in the Star Mountains. The mine will eventually be producing gold, silver, and copper and is still in the stages of construction. John P29NJS is already on location and operating there. Another operator was due at OK Tedi during the second week of April. He is VK3BSO, Stan from Melbourne, and we hope to hear him soon with a P29 callsign. Signals should be good from such a lofty QTH.

Now a bit of history from the area which might be of interest. Prior to World War I and beginning in the late 1880s, the northeastern part of New Guinea and the New Guinea Islands were German possessions. A powerful radio station was in operation at Bitapaka, approximately 45 kilometers from Rabaul. The radio tower was between 80 and 100 feet high, balanced on a glass ball. From there, radio contact was maintained with Berlin via relay stations.

At the outbreak of World War I, when the German transmissions were monitored, it appeared that they were in regular contact with a German warship (the *Scharnhorst*?) in the New Guinea waters. This led to a considerable force being sent by the Australian government for the invasion, to be ready for anything, as it were. The Australian soldiers landed at Kabakaul and proceeded to march towards Bitapaka, about 10 kilometers away. On the way, they ran into a ragged band of German planters and native police, hastily armed with any weapons they could lay their hands on. Shots were fired and a number of men killed, mainly Germans. The radio contacts with the formidable warship had been a sham to deceive the enemy! There was no warship nearby. The capitulation was quick and relatively painless.

There is a final chapter to this particular story: About 50 years later, my OM removed the guy anchors of the radio tower at the site. By then a TB hospital was there, being run by Catholic nuns (a lot of them German), and they wanted to be rid of the three huge cement anchors for the guy wires. RSJs 1 foot in size had been cemented in to give support to the tower. That was the last evidence of the setup.

More news from here next month. See you then.



WEST GERMANY

Mitchell B. Wolfson DJ0QN
Carl-Von-Linde-Str. 35
D-8044 Lohhof
Federal Republic of Germany

Here are some aspects of operating VHF/UHF in Germany. This should assist any of you planning a trip here in the future and give non-visitors an insight into the primary differences between operating in Germany and the United States and Canada.

The most obvious difference between the VHF and UHF bands is the pure lack of "wide open spaces" found on the 2-meter and 70-cm bands, plus the total lack of a 6-meter or 220-MHz band. Our allocation on 2 meters is from 144 to 146 and on 70 cm from 430 to 440 MHz. That's it. Oh, we also have a number of frequencies available and in use on 1240 and above, but now I will concern myself with the two primary bands of 2 meters and 70 cm.

Another major difference is the lack of private repeaters and autopatch repeaters (verboten!). This certainly makes operating repeaters in Germany a different experience than operating in the USA or Canada, but not necessarily a less enjoyable one.

A different attitude prevails in Germany, aside from any difference in mentality. This is due to many factors, such as the limited number of repeater pairs available, the concentrated population centers, and the Class-C (code-free) license. One interesting aspect of operating here is the number of random QSOs going on, exchanging QTH, name, DOK (DARC chapter), etc. This is done on a large scale just to collect QSL cards! Yep, just like on the HF bands in the States, but on a larger scale, QSLs are exchanged for VHF/UHF repeater contacts.

A major reason for this is the DLD Awards program held by the DARC. These awards are given for confirming various DOKs. QSLing in Germany is actually relatively cheap since DARC members can send and receive any number of cards through their local chapter which, in turn, sends the cards through the DARC QSL card computer in Baunatal. In other words, no postage costs! This is a boon to the visitor to Germany, as he or she can, without hesitation, call CQ on a German repeater, perhaps make a nice QSO, and receive a QSL card in a few months to boot. Just don't forget to get some QSLs printed yourself!

Depending on your location, there will always be at least one repeater on each band within working distance. Operating patterns will be like any other industrialized country, so don't get frustrated if you can't make a QSO at 2:00 pm on a Tuesday afternoon. Some repeaters are incredibly busy, such as the "Zugspitze Relay" located here in southern Bavaria. Due to this repeater's tremendous coverage of southern Germany, Austria, and Switzerland, it is really difficult to get a word in edgewise, even late in the evening.

This is, of course, assuming that it isn't being jammed when you want to use it. (Even the disciplined Germans have their share of turkeys!) If you run into this type of situation, you can either go to another repeater or switch to a simplex frequency. The main calling frequency in Germany is 145.500. In addition, most of the DOKs will have a club simplex frequency. For example, my club, DOK C-26, uses the frequency of 145.325. Give it a try when you're in the northern part of Munich!

Many of you have heard about the required 1750-Hz tone burst required in Germany. This is correct, but it is definitely not required for a casual visitor to Germany's population centers. After a repeater has been brought up by tone burst, it will remain on as a straight carrier-operated repeater for a number of seconds. This should allow you sufficient time to gain access. In the worst case, you can always whistle up a repeater. It is cer-

2-METER AND 70-CM STANDARD REPEATER BAND PLAN IN GERMANY

Channel	Input	Output
R0	145.000	145.600
R1	145.025	145.625
R2	145.050	145.650
R3	145.075	145.675

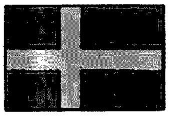
R86	431.450	439.050
R87	431.475	439.075

tainly not worth a large investment in time or money to acquire a 175-Hz generator before arriving here, but it can help under specific circumstances (rural areas, 70 cm, etc.). By the way, Austrian repeaters do not require tone burst.

Last but not least, don't forget that although you may get the impression that most German hams speak excellent English, this is not necessarily true, especially on VHF/UHF. Many of the people you meet may be Class-C licensees with no HF operating experience. Please speak slowly and clearly and have patience with your QSO partner. Enjoy your visit; you may make many permanent friends during your stay!



SWEDEN

Rainer Martinsson SM2DMU
Sikea 3178
S-915 00 Robertsfors, Sweden

I have covered the regulations concerning amateur radio in Sweden, so this month I will give you the details for obtaining a reciprocal license if you are planning your holidays in Sweden. The following is an extract from a memorandum published by the Swedish Telecommunication Authorities.

1. General Rules.
The following rule must be conformed to by any foreign national wishing to obtain a permit to hold and utilize an amateur radio transmitter in Sweden.

On condition that there is no risk of the transmitter or the permit being misused, and provided that its use will not contravene the interest of the community, a permit will be granted to:

Any foreign radio amateur, during a temporary stay in Sweden, who has passed an acceptable test made by the authorities concerned in his native country and co cerning whom satisfactory informatic has been obtained and who, on special e quiry, has been considered fit to ho such a permit in Sweden.
Any foreign radio amateur who has ol tained a permit to hold and utilize a amateur radio transmitter in Sweden ha to follow the direction stated in th Swedish Regulations concerning th Amateur Radio Service mentioned above

2. Application Procedure.
Any foreign radio amateur applying for temporary permit shall submit his appl cation early enough to reach the Swedis Telecommunications Authorities no late than one month before the permit is re quired. The application, which may b written in Swedish, Danish, Norwegiar English, French, or German, shall norma ly be furnished with a pronouncemen made by the licensing authorities in th applicant's native country. The applica tion may, however, be sent direct to th Telecommunications Administration i doing which either a copy of the licens valid in the applicant's native country provided that it was issued not more tha six months ago, or a certificate issued b the licensing authorities in th applicant's native country, proving hi holding of a valid license, must be en closed. Such a certificate must not b older than six months. The applicatio shall also be accompanied by a certificat of good conduct (impunity) issued by th police authorities in the applicant's nativ country. In certain countries, howeve such a certificate cannot be obtained. certificate issued by the applicant's ama teur radio organization must be enclose instead.
When applying for a temporary permit, th following documents *must* be sent in:

1. The application form.
2. A certificate issued by the police au thorities (in certain cases the applicant' amateur radio organization as above).
3. A copy of the valid license or a pro nouncement delivered by the licensing au thorities in the applicant's native countr (as above).

3. Fees.
80 Swedish kronor for a maximum of thre months during a period of twelve month (one year). The time may at most be di vided into four different periods.
The fee shall be paid on the receipt of th invoice.
The application should be addressed to Swedish Telecommunications Radio De partment, Licensing Section, S-123 8 Farsta, Sweden.

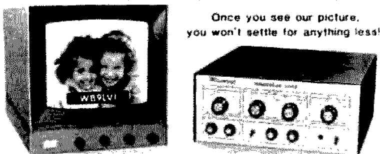
4. Callsigns.
To any foreign radio amateur obtaining temporary permit there will be assigned callsign, consisting of his ordinary call sign immediately followed by /SM and digit stating the district within which th radio transmitter is to be used temporari ly. For traffic exchanged from a mobile o portable radio transmitter, the letters M (MM for vessel) or P, respectively, preced ed by an oblique stroke, may be added t the callsign.

5. Classes of Certificates.
A license for a foreign radio amateur wi be issued and valid for the Swedish clas of certificate corresponding to the clas of certificate assigned to the licensee i his native country.

With this, I end the extract from memo randum no. Rft 1940. Anyone who wishe to obtain further information can write t the above address or call (08)-713-2162 Swedish Telecommunications will be hap py to answer your questions and assis you in your application.

Best Picture at the Best Price - From $495.00
VIDEOSCAN 1000 - HIGH RESOLUTION SSTV

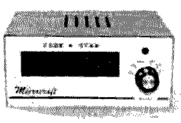
Once you see our picture, you won't settle for anything less!



New generation amateur-standard scan converter sends and receives sharp pictures with up to 16 times better resolution than earlier units. Compatible with existing SSTV plus high resolution modes. Three scan rates, optional call sign and much more. Easy to use. Amateur, phone line TV, surveillance, teleconferencing, etc. Free "How To Get Started In SSTV".
Kit: VS-K $495.00 Wired: VS-F $695.00 Shipping: $8.00

CODE★STAR - PRICED FROM $149.95
More Features Per Dollar Than Anything Else!

Copies code from your receiver!



Improves your code speed too!

Ideal for novices, SWLs and seasoned amateurs. Built-in code-practice oscillator and speaker. Copies Morse, RTTY and ASCII. Large LEDs. Easy to connect and operate. Automatic speed tracking. Excellent digital/analog filtering. 12VDC or 120VAC with AC adapter provided. Compact. 2lbs. Connect computer (like VIC-20)/printer with optional ASCII output port.
Kit: CS-K $149.95 Wired: CS-F $199.95 Shipping: $5.00
ASCII Port Kit: CS-IK $49.95 Wired: CS-IF $69.95

MORSE-A-KEYER -- CW Keyboard Kit: MAK-K $159.95 Wired: MAK-F $199.95 Shipping: $5.00

NEW! EASY, FUN KIT!

New 2 kW tuner kit from TEN-TEC ends constant retuning, guarantees best match, and saves $80! Model 4229 Only $199

Here's the best antenna tuner in amateur radio!
The best quality components, best design, and the best value.
• Reversible "L" circuit guarantees best possible match and widest bandwidth—you may need to tune only once to cover the higher bands and only two or three times on lower bands. • Finest quality parts—ceramic insulators—ceramic inductor form—heavy duty ceramic switch with silver contacts—silver plated roller inductor—• Built-in SWR bridge shows ratios from 1:1 to 5:1 • Built-in 2 kW dual-range watt meter shows power levels from 10 to 2000 watts • Handles 2 kW PEP, 1 kW CW • Frequency range 1.8—30 MHz continuous coverage • Built-in balun—matches variety of antennas, balanced or unbalanced, to 50 ohm unbalanced outputs • Built-in bypass switch • 4-position antenna selector • Coax connectors plus post terminals • Lighted linear dial scale for easy tuning • Black finished aluminum cabinet with stainless steel bail (5½"h x12¾"w x13¼"d) • Also available assembled as Model 229 in slightly different styling at $279.

See your TEN-TEC dealer or write for details:
TEN-TEC, Inc., Highway 411 East, Sevierville, TN 37862.

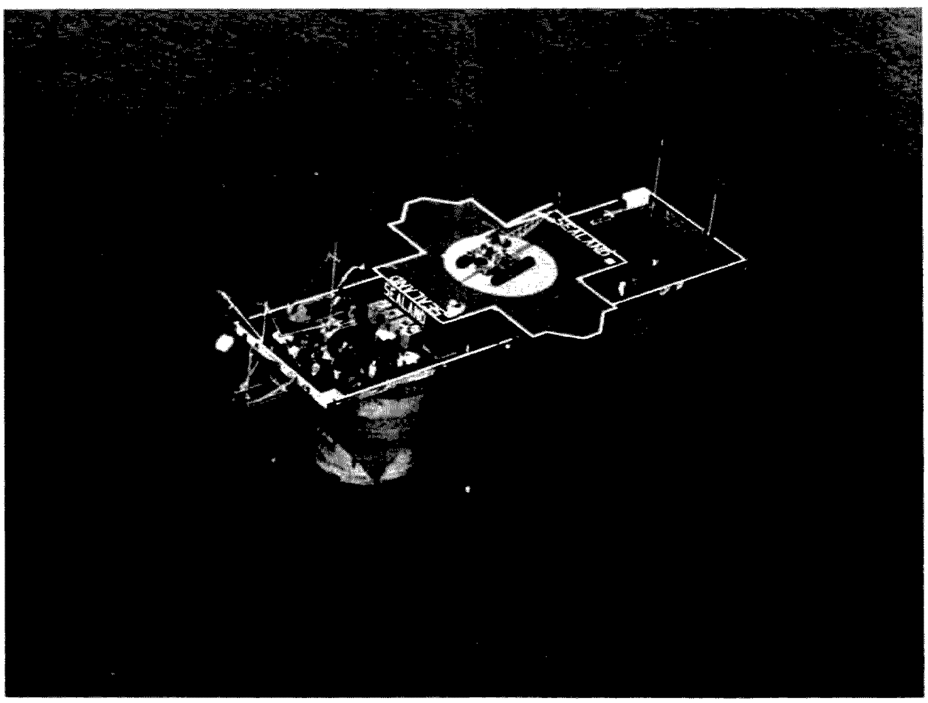
To Go Where No Ham Has Gone Before—Sealand!

An enterprising team of DXers takes to the high seas to work S1, the smallest country in the world.

Let's activate a new country, we thought. Let's just go there and set up our station, we thought. It obviously was a simple thing to do.

But yet here I am, cowering in a soapbox, swinging 40 feet above the stormy North Sea, firmly clinging to the support wires. Then at last! The waves down below me have disappeared and given way to firm ground to step upon. My eyes have stopped looking anxiously through the holes in the bottom of the soapbox lift and turned to catch a glimpse of the smallest state in the world: Sealand.

It had all started more than a year ago. Along with a couple of friends, who later formed the team, I began to think about DXpeditions to the more remote spots of the globe. But the problem was: It's all been done! Then, all of a sudden, one of us came up with *the* idea. There was an artificial island called Sealand in the North Sea outside British territorial waters which was declared independent years ago. The proposal to go there was enthusiastically met by all the amateurs present. So at once we sent a letter to Sealand describing in general the amateur radio service and in particular our idea of a DXpedition to activate the island for the first time.



Sealand on a calm day. (Photo by Southend Air Photography, Ltd., courtesy of Jeff Maynard G4EJA.)

In the meantime, we gathered information about Sealand from newspaper articles and books. The following picture emerged from our studies: During World War II, the United Kingdom built several offshore platforms firmly grounded at the bottom of the sea for air defense purposes. One of them, the one in question, then being called "Roughs Tower," was put up in 1940 about seven miles east of Harwich. Its exact position at 51° 53′ North, 1° 28′ East puts it outside British territorial waters.

The artificial island was maintained for a few years after the war, and upon leaving, the British did not dismantle it. In early 1967, a group of people including Roy Bates and his family went out to the island and took possession of it. On the 2nd of September, 1967, it was proclaimed the independent "Principality of Sealand," and Roy Bates

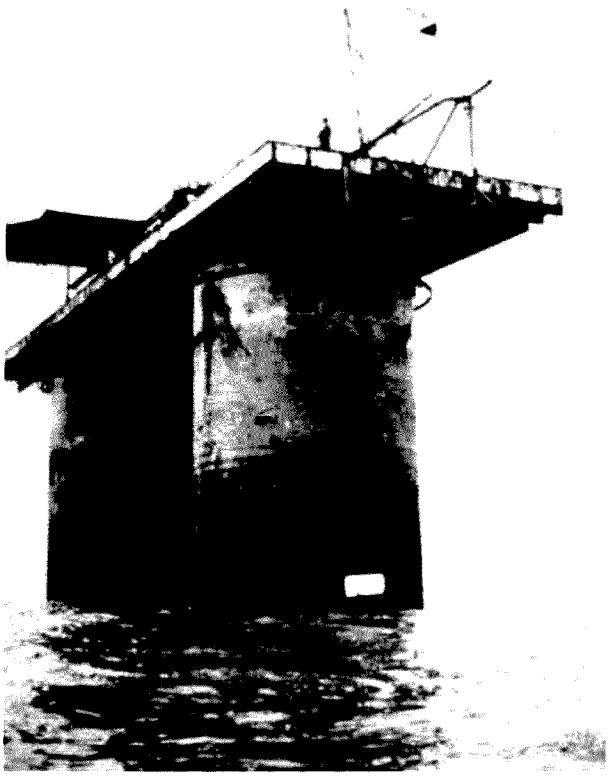


Photo A. Soapbox lift swinging above the waves.

and his wife Joan became Prince and Princess of Sealand. The usual attributes of statehood, like a coat of arms, constitution, citizenship, passports, coins, stamps, and a national flag subsequently were adopted.

Following a few quarrels with the local authorities, Prince Roy was summoned to appear at a number of British courts, but in each case it was ruled that Sealand was outside the United Kingdom and therefore not within its jurisdiction.

The only "nationwide" crisis which shook the small state occurred in 1978 when the previously-dismissed foreign minister successfully launched a coup d'etat. But his interregnum did not last long. After only six days, the principality struck back. A rapid-deployment force of four people returned by helicopter and retook possession of the platform.

A public session of the Sealand Court of Justice sentenced the leader of the coup to seven weeks of detainment. After that, he finally was allowed to leave the country. Since then, the history of Sealand has continued a lot smoother.

After getting to know this stormy history, we did not really expect a positive answer. But to our great surprise, we were invited by Prince Roy himself to come and to celebrate the 15th anniversary of Sealand's independence. Immediately, we began working out the details of the DXpedition. The team consisted of four members: Butz DL6PE, Geri DK8KW, Dick DC5BT, and Ben DF2AO. Lots of equipment, coax strings, orange juice, food, and other bits and pieces had to be obtained and coordinated properly until we had taken care of everything we thought useful.

Finally, on the 31st of August, 1982, we packed our bags and left Cologne with two cars to reach Oostend in Belgium later that night. There we boarded a ferry. After having managed to take a nap on board, we reached Dover very early in the morning. Our voyage continued round the mouth of the river Thames until we reached Southend-on-Sea

STATEMENTS ISSUED BY THE PRINCIPALITY OF SEALAND

During the 39/45 war, Great Britain established an artificial island on the High Seas. This island was equipped with radar and heavy armaments and occupied by some two hundred servicemen. The task of the island and its inhabitants was to guard the approaches to the Thames Estuary where large and vulnerable convoys of shipping were assembled. Some time after the cessation of hostilities, the island was derelicted and abandoned by the British Government.

In the winter of 1966, a British family took possession and commenced the task of equipping and restoring the island. On the 2nd September 1967, they hoisted their own flag and declared the existence of a new State—the Principality of Sealand. Their rights and claims of Sovereignty over the island and its territorial waters have been ratified time after time over the intervening years by National Courts and leading international jurists.

European States have—during disputes involving Sealand—stated that they have no rights or authority in Sealand and the major European States have repeatedly given de facto recognition to the existence and the Sovereignty of Sealand.

Over the years since the declaration of Statehood by Sealand, the family lived a free frontier lifestyle. They made and enforced the laws of Sealand. They faced and drove off armed attackers and on one occasion a member of the family was actually kidnapped by armed men and forcibly taken to a foreign country against his will.

Sealand came under threats from hostile naval units from other States; in the early days of independence, there were the most determined attempts made to isolate and starve out the island. The elements and the sea had to be fought constantly with a relentless determination. It was a very busy, active, and adventurous life for the family and their fellow Sealanders and they all thrived on it.

Sealand issues her own coins and postage stamps and runs a postal service between Sealand and Britain, the British postal services collect mail for Sealand's collection and delivery to and from the island.

It is now planned to extend Sealand by reclaiming land from the sea and by building leisure and industrial complexes. There will be a modern freeport for the transhipment of cargo from larger to smaller vessels for the better distribution of freight throughout Scandinavia and Northern Europe. With the potentials and the planned developments of Sealand, it is unquestionably the greatest commercial adventure of this century.

Perhaps there is still something of the old buccaneering spirit about Sealand, but it must be made quite clear that Sealand is a realistic and very modern fact. This spirit will ensure that the Sealand story will continue and that Sealand will go on to emphasize the freedom and determination of the individual and to bring back the excitement and dash of the old merchant adventurers. Sealand is unique. There is nothing anywhere in the world like Sealand and the development of the Sealand potential will also be unique.

Bureaucracy will be at an absolute minimum and free enterprise and bright ideas will always be actively encouraged and rewarded without the State taking the larger share of earnings or penalizing in any way the true spirit of adventure and hard work that it is our aim to engender. The only taxes payable on Sealand will be those decided by businessmen controlling the Sealand State Corporation in order to raise money necessary to run the island.

Photo B. Antennas and orange juice being unloaded by Dick (left) and Geri.

Photo C. Butz operating the CW station inside the tower.

where Prince Roy received us in his private apartment. After a short audience which included the issue of our personal licenses with the S1 calls, we headed for Felixstowe where our boat to Sealand awaited us. It was not a very large one, but it did rather nicely on all three trips necessary to get everything across.

The most exciting stage of our trip, however, was the last one. In Photo A, you can see the aforementioned soapbox lift almost touching the waves. After the overwhelming moments described in the first paragraph above, the great instant had arrived. (It was a small step for a ham . . .)

The soapbox lift had to work hard to get all the luggage "upstairs." Photo B shows Dick working and Geri assisting at the unloading of the box. One of the orange juice packages was torn to pieces, but, luckily, that was the only casualty. The reception committee was formed by Prince Michael of Sealand, son and successor-to-be of Prince Roy, who gave us more than just a helping hand during the erection of masts and antennas.

After we went through the necessary passport formalities, the HF stations, consisting of two IC-720As, a five-band GPA, and a windom, were put up immediately inside one of the concrete towers at about sea level. The first station finally was on the air on the 1st of September at 1956 UTC. Soon afterwards, Butz took up telegraphy at the other station (see Photo C).

You can imagine that very mixed reactions were instantly flooding in from our QSO partners around the world. The majority expressed their pleasure that at last Sealand was on the air; others did not believe a word, but obviously did not want to miss us. There even were two or three "imitators," but they soon gave up.

In the same tower as our shack we also were assigned a living room. (Each tower includes seven stories of circular rooms, and on top of the platform there are another eight rooms.)

On the next day, the anni-

Photo D. The 2m station operated by Ben.

Photo E. Dick (left) and Geri enjoying a sunny day out in the "countryside."

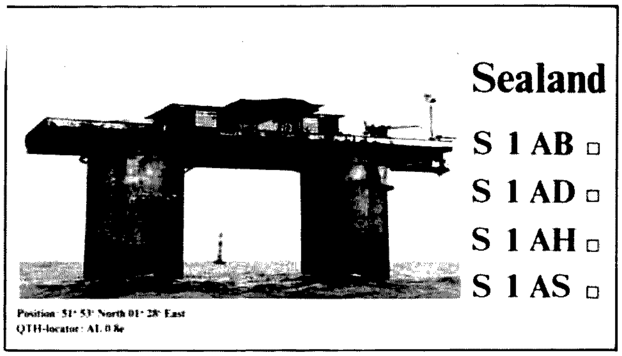

Fig. 1. DXpedition QSL card.

versary day, we put up the 2-meter station, a TS-700S, a 60-Watt linear, and a 10-element yagi beam. Photo D shows Ben working 2m DX in the 2m shack on top of the platform. In general, not-too-regular shifts added up to an almost continuous operation on HF and VHF.

During our time off we had quite a few interesting conversations with the three natives present, so a lot of additional information about Sealand was supplied to us. Sometimes, when the weather was nice, we could even take a sun bath—see Photo E.

All in all, we were given the impression that we were very welcome on Sealand. Therefore, the five days really passed in a jiffy, and soon the 6th of September, our day of departure, had arrived. The crossing to England was a lot rougher than it had been on our way to the island, but again nothing suffered any damage. Again we crossed the channel at night, and then returned to Cologne.

After our return we sat together and summarized our DXpedition. About 3600 contacts were established with more than 80 countries on all continents. One thousand QSOs were made on 2m, almost exclusively by Dick. We had great fun, and we erased the last white spot on the radio amateur's world map. So now this, too, has been done. But we'll return to Sealand in a few weeks, possibly before you read this. Anyway, please listen for us on the usual DX frequencies in SSB and 22 kHz from the band edges in CW. Hpe cuagn. Ben DF2AO. ■

Constitution of the Principality of Sealand

1. Every person has the right to liberty and justice.
2. Every person has the right to exercise his own beliefs provided only that such beliefs do not infringe upon the beliefs and well-being of others.
3. The freedom of the individual can be restricted only by the due process of law.
4. All individuals are equal before the law and no one may suffer prejudice for any reason.
5. The legal system is based on the British Common Law and the British Law of Contract with certain exceptions.
6. Any ordinances passed in Sealand by the Senate properly constituted will exclude and take precedence over such Laws.
7. The National language of Sealand is English and all official documents must be in that language.
8. All companies registered in Sealand are subject to the same laws as individuals.
9. Every person shall have the right either to join or refrain from joining a Sealand Trade Union but no person will be permitted to attempt to coerce any other person so to join and no trade union other than a Sealand Trade Union will be recognized on the island.

1001 Uses for the 9400

Experiment with this cheap chip. It's the IC you've always wanted, with applications you've never dreamed of.

Allen S. Joffe W3KBM
1005 Twining Road
Dresher PA 19025

The 9400 is now available, off the shelf, from Radio Shack. Part #276-1790 priced at $3.49 will allow you to take a flying leap into the world of IC exotica. The 9400 is a 14-pin DIP that may be used in one of two modes. It will convert an applied voltage to a frequency or will, with some slight circuit rearrangement, convert an applied frequency to a dc voltage.

Briefly described, the chip is a marriage of bipolar and CMOS technologies which utilizes the principle of charge balancing. This is a fancy buzzword for the process which takes an input voltage and converts it to a current which is then operated on by an "on chip" integrator. The integrator capacitor charge is monitored by a comparator and at a predetermined time the charge is "dumped" and the circuit recycled. We could struggle all over hell's half acre of high-flying technological niceties, but some simple (on the surface) ideas of how to use the IC seem to be the better part of valor.

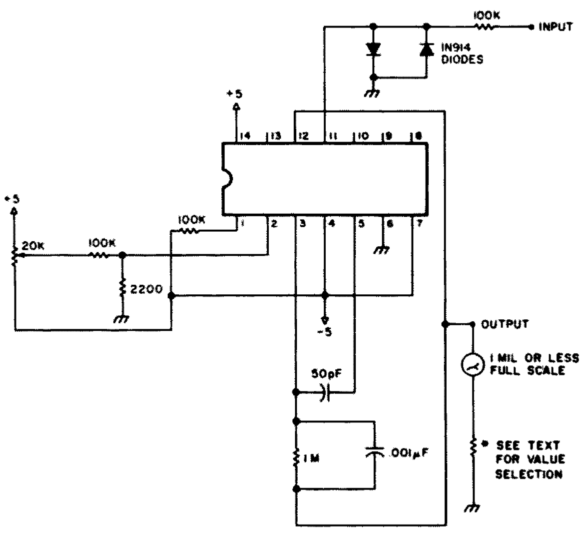

Fig. 1. The 9400 used as a dc-to-10-kHz frequency-to-voltage converter. Note: Pins 8, 9, 10, and 13 not used.

The IC will work either with a split supply of plus and minus five volts or from a single supply of ten to fifteen volts. For many reasons, my personal preference goes for the split supply. Since, by definition, the applications will be voltage-sensitive, your supply voltage should be at least zener-regulated.

For the first flight out of the barn, examine the circuit of Fig. 1. This shows the use of the 9400 as a dc-to-10-kHz frequency-to-voltage converter. In basic English, if you put a one-kHz tone (waveshape is unimportant) into the circuit, the meter at the output would show a voltage of some 360 millivolts. If you double the input frequency, then the output voltage doubles. If you halve the input frequency, then the output voltage falls by a factor of two. The rise and fall of the output voltage versus the input frequency is very linear; hence, it is no trick at all to calibrate the output voltage meter in terms of input frequency over the range of interest.

Circuit setup is simple. Merely adjust the 20k pot for a zero reading of the output meter with no signal applied and that is that. To what use can we put the circuit? Look at it as a low-cost dedicated frequency meter. You can put it across the output (sample) from a dc-to-ac converter and know that the frequency coming out is indeed 60 Hz. You could calibrate the meter for mark and space frequencies of your RTTY setup. In

any situation where you want to keep tabs on an audio frequency up to 10 kHz, this simple handful of parts will give you a way.

By now you may get the idea that this is a versatile item, and you are right. For the gentlemen who know that CW is still a viable part of the ham art, try this on for size. The circuit of Fig. 1 makes an interesting variety of CW filter. Due to the use of a comparator as part of the chip's innards, a comparator with a threshold of some 200 millivolts, some good things are available. Feed the voice coil output of your receiver to the input of what is now our "CW purifier." Place an audio amplifier right across the output. Tune in a CW signal and advance the gain control of the receiver until you hear picture-pure code in the speaker. Almost all of the background garbage vanishes, be it Russian BCI on forty meters or the guy up the road a few kHz. The CW note is quite pleasing to the ear, the waveshape being a sawtooth ramp of the same frequency as the beat note applied to the input. Weak off-frequency stations and sideband splatter just vanish.

There is one fly in the ointment after all . . . Murphy lives! If the signal fades so that the audio level is not high enough to trip the threshold of the comparator, you get nothing out but beautiful silence. This may mean a bit of twiddling with the audio gain control of the receiver, but the results overall are quite impressive.

Let's review a bit of the bidding before looking at the 9400 in its other mode. The two diodes across the input are safety valves to prevent any exuberant voltage in excess of the IC safety zone from sending it to IC heaven. The circuit as configured has a limit of 10 kHz, above which the input voltage versus output voltage is no longer linear. To use the device as an analog frequency meter, merely wire up what you see. If you want to use the device strictly as a CW filter, then replace the meter circuitry with a 47k resistor from the output pin to ground. Couple out of the resistor with a .005-μF capacitor which will de-thunk the output which might otherwise be generated by the Morse flowing through it. Remember to at least zener-regulate the supply which will have a current demand of ten mils or less.

Leaving it to your originality to come up with other uses of the 9400, let us examine Fig. 2, the circuit that becomes a voltage-to-frequency device. Simply put, any voltage (ac or dc) that is put into the circuit produces a frequency at the output. Within the linear range of the circuit (10 Hz to 10 kHz), this output frequency is in direct proportion to the applied voltage. To pick some random numbers: If one volt in gave a 5-kHz tone at the output, then 2 volts in would give 10 kHz at the output. As there are two output pins shown, we have to watch which one we use as they differ in one respect. For a given voltage input, the output frequency at pin 8 will be twice the frequency as at pin 10, as there is a divide-by-two built into the 9400, the output of which appears at pin 10.

While most of the uses for this configuration get a bit abstruse, the simplest idea is to connect the input to +5 volts through a variable resistor network and vary the input voltage. Listen to the output and you will hear the frequency vary with the applied voltage. My 9400 produces one kHz with an applied voltage of 1.3 volts and just a shade over 2 kHz with double the applied voltage. This frequency was measured at pin 8. Measured at pin 10 (due to the divided frequency available), these frequencies would be half those appearing at pin 8. You can see the sensitivity of the frequency change by appreciating that one millivolt changed the frequency by one Hz.

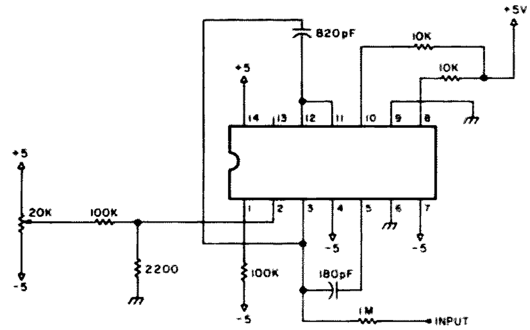

Fig. 2. The 9400 used as a 10-Hz-to-10-kHz voltage-to-frequency converter.

A non-related (hamwise) application readily becomes apparent if you shut off the power supply to the unit when it is set up as an oscillator. As the filter capacitors drain down, the frequency falls in a fine siren-like fashion. If you have a function generator capable of producing triangles, ramps, pulses, and square waves, it is possible to get all sorts of weird and/or pleasing noises upon application of these waveforms to the 9400. Everything from motorboats to phasers and sirens is readily achieved.

Getting down to the nitty-gritty, the voltage-to-frequency mode does not seem to lend itself to simple implementation for the ham. For openers, contrast the simple setup of the frequency-to-voltage mode (which consisted of turning a pot until an output meter read zero) with the following setup for the voltage-to-frequency mode: Set the input voltage to 10 millivolts and trim the zero adjust pot to obtain an output frequency of 10 Hz. Set the input voltage to 10.00 volts and trim either the input resistor or the 180-pF capacitor until the output frequency is 10 kHz.

Now let us consider some of the applications that appear. We could construct a simple audio voltmeter that would tell us that one voltage is higher or lower than another, which might have some possible use. We could use it as a bridge balance indicator. We could use it in any situation where a sensor changes ohmic value, causing a change in output voltage to produce a change in frequency which might be measured by a standard frequency meter or a 9400 connected as an F/V converter using an analog meter. Such an application might utilize a thermistor for remote temperature sensing. Without belaboring the situation unduly, unless you get interested in some form of ham-connected digital transmission or something that requires some sort of FSK that naught else will provide, the F/V mode of the 9400 will be of greater value than the V/F mode under discussion.

Keep in mind that the dual uses of the chip will often be complementary so that the V/F and the F/V modes used together will produce a desired end result. The modest investment in the 9400 and some time learning what it can do are well worth the money and time. Ham radio has and is going through various technological phases. Keep up with them to a degree and many unexplored facets of the world's greatest hobby will become your yellow brick road to happiness. ■

Propagation Explosion on 220

This theoretical inquiry into the properties of 220 MHz yielded some unexpected results. Find out when and why your signal will be at its best.

Not long ago, I was talking to a ham friend of mine who is locally considered as quite learned in the ways of the black magic world above 2 meters. When I raised the subject of 220 MHz and the appalling lack of local activity on that band, he gave me a somewhat irritated look and dismissed the issue by saying, "Who'd want to use those frequencies? You can't get out of your backyard with them, anyway."

Wasn't that what they said at one time about everything below 200 meters? A rather strange attitude, I thought, for a man who is supposed to be savvy about that part of the radio spectrum. The more I thought, the more curious I became about the 220-MHz band. Surely, this good ham and electronics professional who daily uses the many amateur and commercial frequencies above 148 MHz couldn't be discounting their usefulness for communications! Or was my friend trying to say that some mysterious radio anomaly existed just around the 220-MHz band which rendered only it useless? (My rather overactive imagination quickly conjured up a sort of propagational black hole which sucked up all energy from transmitters in that region.) Obviously, none of this was true. Yet, the myth of 220 as a band that offers little to amateurs seems to persist among a lot of us in the fraternity. I wanted to know why.

Could the myth be based, partly, at least, on some propagational features of 220 that are alien to the understanding and experiences of most lower-frequency operators? In earlier years, it was generally true that almost all VHF work was done at essentially local distances (i.e., up to about 30 miles). Even today, particularly in densely populated areas, this range is still probably typical of the average amateur communication path. Therefore, I reasoned that if any unusual propagational behavior degraded signal strength at 220 on paths of this length, especially during the earliest days of experimentation on this frequency, it might be part of the explanation of why this much-neglected band got its less-than-good reputation then, and why the band maintains its reputation with amateurs like my friend even to this day. I needed to study this possibility, and I needed an adventuresome, experimentally-inclined partner to help me. Jim K9MLK, who was located about 10 miles from my station, gamely agreed to help.

How's the Weather on 220?

Though far from being a scientific type, the next requirement I would have to fulfill would be carrying out my investigation in as scientific a manner as possible. Therefore, a working hypothesis was in order. I began with a piece of information that even relative newcomers to VHF have known for years: Weather changes in the lower atmosphere can affect propagation at these frequencies. But what, *specifically,* about the weather would change 220-MHz propagation? What about the effects of solar activity? Though generally discounted as a factor, could it be ruled out entirely here? And could I discount the effects of the Earth's magnetic field? I arbitrarily set a hypothesis which would include most common elements of the weather and of solar and geomagnetic activity. I decided that K9MLK's 220-MHz signal strength, as received at my location, would probably vary with changes in air temperature, humidity, the level of the cloud ceiling over the transmission path, barometric pressure, geomagnetic fluctuations as measured by the "A" index, and solar flux numbers. The latter two types of data would be provided on each appropriate test day by the National Bureau of Standards station, WWV, and the National Oceanic and Atmospheric Administration (NOAA). Humidity and temperature measurements could be taken at my station location, but cloud-ceiling data and barometric-pressure readings, because of the lack of accurate home instruments, would have to be obtained from the flight service at the local airport.

Setting Up the Test

The remaining things which required a decision before beginning our tests were choosing transmission mode, antenna, polarization, power level, station equipment, and, lastly, a method of measurement for the received signal which would be accurate and yet would be easy to use. Two criteria would have to be satisfied in making these decisions. First, our station equipment would have to operate in some mode which could provide some constant-carrier signal for meaningful comparison. This constraint almost automatically dictated that we use CW, AM, or FM. Second, in the interest of scientific control, what was true with one station had to be true with the other, that is, power levels, antennas, antenna height, model(s) of equipment, type of feedline, method of measuring the received signal, and the like had to be duplicated on both ends of the transmission path as nearly as possible. We also would have to duplicate the time of day each time the experiment was run so we could minimize any effects other unknown but *time*-related variables might have on our signal-strength measurements.

Picking station gear was relatively easy and consequently came first. Two AM transceivers became available almost immediately, so AM became the mode of choice because of convenience. The transmitter sections were low powered and thus offered an unexpected opportunity. Since each of us would be putting only about 1/2 Watt into our feedlines, we felt that, at a distance of 10 miles, we should be able to detect even relatively small signal changes which might be the result of propagational shifts. It was our belief that higher power levels might have masked this phenomenon over such a short path. As for polarization and antenna decisions, horizontal was chosen since it has traditionally been used in most weak-signal work. Both stations, then, were outfitted with horizontally-mounted, homemade 5-element quagi beam antennas, and both were fed with RG-8/U foam coaxial cable. Lastly, in an attempt to abide by the rule of duplication, both antennas were to be mounted as close as possible to a height of 40 feet. That would, it was hoped, minimize individual station differences based on antenna height gain or feedline length.

The final decision to be made concerned choosing a method for measuring and comparing the levels of received signal. Neither of us felt particularly comfortable working in any measurement scale that was nonlinear, so a very simple yet reliable alternative had to be devised. Because both receivers employed circuits with excellent agc characteristics, we simply decided to measure the differences in associated voltage at a no-signal and a signal-present condition. Since the voltage figures used for final data analysis are *difference* numbers, any internal voltage variations or any transient external receiver conditions such as an increase in line noise which might increase the total voltage reading during the experiment are essentially minimized as a data bias. To further minimize bias caused by variations within each of our stations, we both measured signal voltages in this manner and then these readings were averaged to produce the day's final data. Voltage readings were taken at both ends of the experiment with each station transmitting a constant-amplitude 1000-Hz audio tone to the other for a period of 60 seconds.

Data was collected in this manner over the period of November 1, 1979, to March 25, 1980. This period was purposely chosen since it represented the best of several possible experimental conditions. First, we felt we would best be able to test the influence of warm and cold air inversions which are so common in this part of the midwest in the fall. Second, we would experience a wider range of temperature and humidity extremes during this time than probably any other. And lastly, this particular time period was predicted to be near the maximum for solar activity in the current solar cycle. So, if the sun had any influence on propagation at this frequency, we felt that it probably would be most evident at this time.

The Expected and the Not-So-Explainable

The results of the experiment are portrayed in Figs. 1 through 5. Each of these graphs shows a correlation line between received signal and data from one of the five meteorological or geo-solar variables mentioned in the starting hypothesis. For those of you who are mathematically inclined, these correlation lines were derived by using standard regression methods.

Results range from the expected to the almost unexplainable. Fig. 1, for example, shows the relationship between signal strength and the percentage of air humidity. A statistically significant negative relationship between the two is strongly suggested here. The findings indicate that as humidity levels declined in the atmosphere over the transmission path, signal strengths increased in response. According to Thornburg in the March, 1978, *QST*, while this phenomenon is known to occur with signals transmitted in the gigahertz range, it is not typically associated with propagation at frequencies this low. Yet the effect at

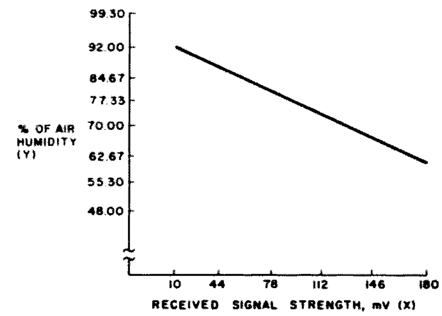

Fig. 1. Relationship between humidity and signal strength.

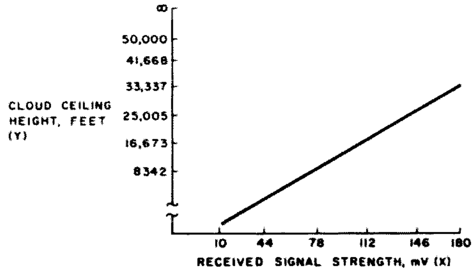

Fig. 2. Cloud ceiling height vs. signal strength.

220 appears to exist. (It was interesting to note that during our test, during periods of high moisture, such as rainy or snowy days, signal strengths which typically ran at S9 or better under more clear conditions, would plummet into the noise level.)

Fig. 2, on the other hand, shows the relationship between signal strength and cloud-ceiling height in feet. Some intuitive feeling suggested prior to this experiment that at this frequency and above, a low cloud ceiling might act almost as a pipeline or duct. In other words, it might concentrate the signal and its strength. Also, the possibility occurred to me that if a cloud layer did duct the signal, this phenomenon might exist if and only if the cloud layer were at some critical height above ground. That is, signal reinforcement might take place only with the cloud layer present *above* or *below* some special height. The data portrayed in Fig. 2 suggests the opposite is more likely. A mild correlation was found between signal strength and ceiling height and this correlation was statistically significant. Yet the relationship was positive. So, here the data was suggesting that as the cloud ceiling rose, signal strength also slowly rose. This finding doesn't give much support to the belief that a low cloud ceiling will increase signal strength. Nor did the data analysis support the notion of a particular critical ceiling height above any certain level.

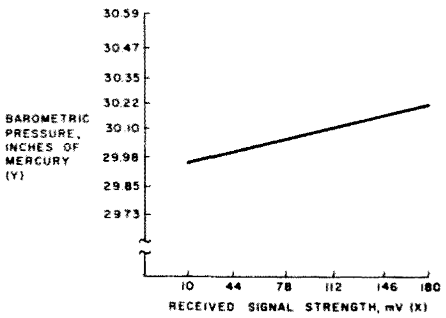

Fig. 3. Barometric pressure vs. signal strength.

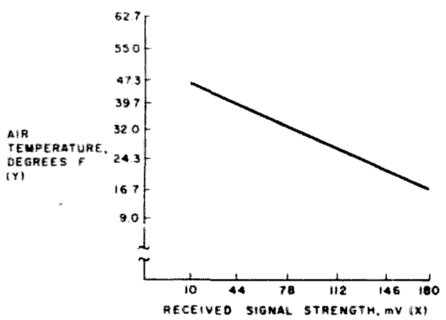

Fig. 4. Air temperature vs. signal strength.

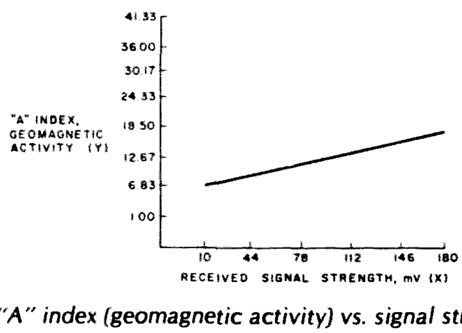

Fig. 5. "A" index (geomagnetic activity) vs. signal strength.

It is difficult to know how important this apparent relationship is. One possible explanation for the correlation between signal strength and cloud height might be found in the fact that periods of high humidity are most frequently associated with wet and stormy conditions, and these conditions are normally accompanied by lower cloud ceilings. Thus, the correlation between cloud height and signal strength may, in fact, be only an indirect reflection of the relationship between high humidity and low signal strength as was discussed earlier.

Fig. 3 represents a phenomenon that is somewhat harder to explain. Here a weak positive correlation was found to exist between signal strength and barometric pressure. In short, the data indicates that as barometric pressure rose (an event typical of the coming of clear dry weather), signal strength generally tended to increase as well. This finding should not come as any surprise to veteran weak-signal operators on 6 and 2 meters who know that the changeover between low- and high-pressure weather systems can produce some pretty nice DX contacts at times. What will be surprising to the mathematically inclined reader is the fact that the relationship on 220 MHz was not found to be statistically significant. At least mathematically, the apparent changes in signal levels could not clearly be explained by changes in barometric pressure.

Again, a *possible* explanation exists. As was just mentioned, it is well established and commonly known that weather-front boundaries involving differences between low- and high-pressure air masses do enhance signals over *long* paths, but this experiment was conducted over a relatively short transmission path. It was probably true that over our 10-mile path no sizable differences in barometric pressure existed during our tests, and thus no sharp reflecting air-mass boundaries were available to provide us with significant enhancement of our signals. Certainly, more testing of this idea should take place before the short-path effect of barometric pressure changes on signal propagation is ruled as unimportant.

The next relationship, signal strength and air temperature, is much clearer. Fig. 4 shows a strong negative correlation line between the two, thus suggesting that as temperature over the transmission path lowers, signal strengths tend to increase. This correlation was found to be statistically significant, thus giving some weight to the contention held by many old-time VHF operators that signals were often stronger on a cold, clear day.

Geo-Solar Activity and Its Effect

The effects of the sun interacting with the Earth's magnetic field were, at least by the criteria we used, predictably disappointing. Fig. 5 shows the data comparing the NOAA "A" index with signal strength on 220 MHz. For those not familiar with this measurement, the "A" index is a linear scale which is designed to show variations in the magnetic field of the

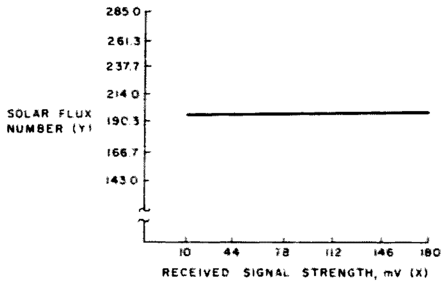

Fig. 6. Solar flux number vs. signal strength.

Earth. This data is collected daily and transmitted hourly by WWV. Although a very weak positive correlation was shown to exist here, this correlation was not found to be statistically significant. In fact, the correlation is so weak as to indicate that the relationship between the two possibly might be caused by strictly random events. Again, it should be remembered that the lack of a significant relationship here for short-path propagation does not in any way prove that geomagnetic variations are insignificant in shaping 220-MHz propagation over longer paths.

The interaction of solar activity and signal strength, as in the prior comparison, also was minimal. Here, as indicated in Fig. 6, though, the lack of any statistically-significant correlation between what are essentially sunspot count numbers and 220-MHz signals was even more evident. Again, any positive correlation of the data was so small as to be explainable in terms of random events or accidents. Thus, a reasonable conclusion to be drawn from this last comparison might be that regardless of changes in the sunspot number, signal levels over short paths on 220 will probably not be improved or hurt significantly as a result.

What Does This All Mean?

The original intent of our experiment and this article was to shed some light on the behavior of 220 MHz. It was felt that if this band were better understood, even in just the area of signal propagation, other amateurs might be more encouraged to explore the band for the first time.

What we found can be summarized in very plain words as a fascinating propagational picture. 220-MHz propagation is not as mundane and as simple as it might seem to the uninitiated. Nor is it so formidable or so unpredictable that the average ham could not understand and even take advantage of it. What does appear to the band user is a colorful propagational world which is probably not quite like what most of us experience on 2 meters and below. Here, over relatively short distances you can expect your signal strength to vary with air temperature, humidity, cloud conditions over the signal path, and possibly to some extent, even barometric pressure. Expect high temperature, high humidity, the presence of precipitation, and the presence of low cloud ceilings to degrade signal levels. On the other hand, our experiment predicts that you can expect relatively cloud-free, cool, low-humidity days (days typically characterized by high barometric-pressure readings) to produce much better signal reports. However, other than providing pleasant conditions in which to work, the sun and its associated sunspot activity cannot be counted upon to either increase or decrease 220 signals over a short path. This lack of effect also appears true for changes in the Earth's magnetic field, as well.

One additional word about the methodology employed here and about the interpretation of our findings is in order before concluding. We realize that more scientific and perhaps more precise results might have been achieved had this experiment been performed with professional equipment and personnel involved. It was, however, performed under conditions which are consistent with the Amateur Radio Service. Consequently, the reader is reminded that the conclusions drawn here are only meant to suggest the indication of *possible* relationships. That is all that the mathematical tools used in the analysis of the data may claim anyway. Certainly, more complete and controlled research should be conducted in these areas and other members of the hobby are heartily encouraged to do so.

The author wishes to extend his sincere thanks to Jim Genisio K9MLK, without whose help this research might have been impossible, to Sr. Rosemary Schmalz, PhD, Mathematics Department, St. Mary of the Woods College, for her assistance in computer analysis of the data, and also to the National Oceanic and Atmospheric Administration, Boulder, Colorado, for their help by providing solar data and general information.■

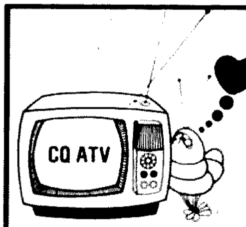
BITTEN BY THE ATV BUG?

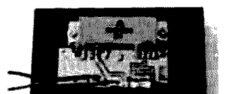
Let P.C. put you on the air and SAVE!

Complete System price

$249.00 SAVE $13.00



TXA5-4 Exciter/Modulator ...... $89.00 ppd.
Wired and tested module designed to drive PA5 10 watt linear amplifier. The 100 MHz crystal design keeps harmonics out of two meters for talk back. Video modulator is a full 8 MHz for computer graphics and color. Requires 13.8 VDC reg. @ 70 ma. 80 mw output power. Tuned with crystal on 439.25, 434 or 426.25 MHz.
Dual frequency model available .... $115.00 ppd.



PA5 10 Watt ATV Power Amplifier . $89.00 ppd.
The PA5 will put out 10 watts RMS power on sync tips when driven with 80 mw by the TXA5 exciter. 50 ohms in and out plus bandwidth for the whole band with good linearity for color and sound. Requires 13.8 VDC reg. @ 3 amps.

FMA5 Audio Subcarrier Generator . $29.00 ppd.
Puts audio on your camera video just as broadcast does at 4.5 MHz. Puts out 1 V p-p to drive TXA5. Requires low Z mike, 150 to 600 Ω and 12 to 18 VDC @ 25 ma. Works with any transmitter with 5 MHz video bandwidth.

TVC-2 ATV Downconverter $55.00
Stripline MRF 901 preamp and double balanced mixer digs out the weak ones and resists intermod and overload. Connects between UHF antenna and TV set. Output channels 2 or 3. Varicap tuner 420 to 450 MHz. Requires 12 to 18 VDC @ 20 ma.
Supersensitive TVC 2L with NE64535 preamp (.9 db N.F.) .... $69.00 ppd.

Call or write for our complete catalog of specifications, station setup diagrams, and optional accessories which include: antennas, modulators, test generators, cameras and much, much more. See Ch. 14 1983 ARRL Handbook.

18 kV with No Transformer

You need high voltage, but surplus transformers can't turn the trick. Try this solid-state solution.

One drawback of the proliferation of solid-state components has been the disappearance of high-voltage power supplies and components, particularly high-voltage transformers. This became clear about two years ago when I needed a negative 600-volt supply to test a surplus reflex klystron. The current requirements were less than one hundred microamperes. After realizing the junk box no longer contained such traditional items as a 250-0-250-volt television power transformer, I had to come up with a different solution—voltage multipliers.

A times-four multiplier supplied the needed negative 600 volts directly from the 117-volt line. Later, a small transformer with a 115-volt secondary was used to isolate the supply from the ac mains for safety.

Since then, I have made several high-voltage, low-current supplies ranging from 18 kilovolts to 600 volts for applications including infrared image converters, a two-inch oscilloscope, and a simple Geiger counter.

A basic times-four multiplier schematic is shown in Fig. 1. As the input voltage alternates between plus E and minus E, it is easy to see how the circuit multiplies the voltage. During the first half cycle, C1 is charged through D1 to plus E volts. During the next half cycle, C1's voltage is added to the input and charges C2 through D2.

Because some of the charge on C1 is transferred to C2, reducing the voltage on C1, several complete cycles are required to charge C2 to two times peak input voltage E. But, for clarity, let's assume that C2 is fully charged to 2E. During the third half cycle, the voltage across C1 bucks the input and the voltage across C2 charges C3 through D3 to 2E. Now, during the fourth half cycle, the sum of input voltage E plus the voltage across C1, E, plus the voltage across C3, 2E, charges C4 through D4 to a total voltage of 4E.

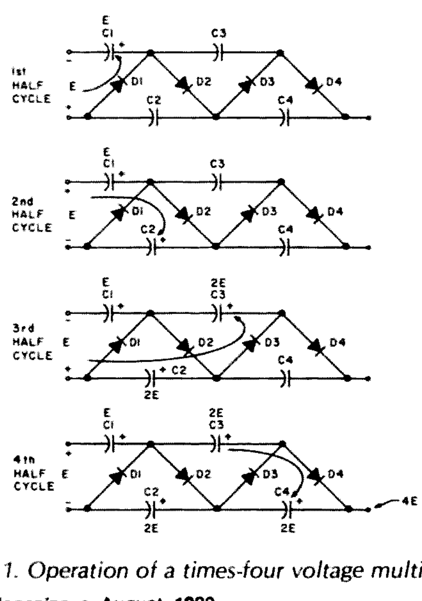

Fig. 1. Operation of a times-four voltage multiplier.

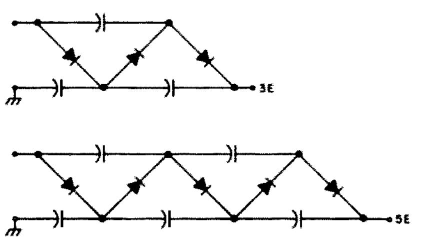

Fig. 2. Schematic of times-three and times-five voltage multiplier.

However, the voltage across C2 bucks the charging voltage and therefore C4 is charged to 2E. The output voltage is the sum of the voltage across C2 and C4, or 2E plus 2E, or simply 4E.

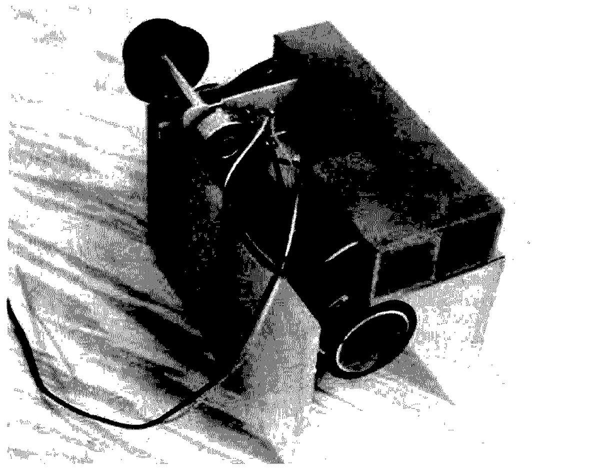
By adding pairs of diodes and capacitors, outputs of 6E, 8E, or higher can be obtained. The breakdown voltage of the individual diodes and capacitors should be greater than twice the peak input voltage.

This is fine for multiplication by even numbers, but what about multiplication by odd numbers to get 3E, 5E, or odd multiples of the peak input voltage? Examining Fig. 1, the sum of the voltages across C1 plus C3 is 3E, but there is also an ac voltage of E volts peak present. By switching the input ac and ground connections, the ac voltage will be on the other capacitor chain and odd dc multiples of the input are obtainable. See Fig. 2. The circuits shown in Figs. 1 and 2 are for positive output voltages. To get negative output voltages, all that needs to be done is to reverse the polarity of each diode (and each capacitor if electrolytics are used).

As an example, I needed an 800-to-1000-volt supply for a Geiger-Meuller tube for a demonstration of radioactivity. I had a 115-volt secondary, 15-milliampere transformer available. Using a times-six multiplier would yield (115) (1.4) (6) = 966 volts.

A multiplier was built with six 1N4006 diodes and six .0075-uF disc ceramic capacitors. The no-load output was measured to be 920 volts. Out of curiosity, I measured the output voltage as a function of the load resistance. The results are plotted in Fig. 3. Actually, Fig. 3 shows two curves, one using .0075-uF capacitors and one using 0.1-uF capacitors. Obviously, the output regulation is much better with the larger capacitors. However, the light loading of the Geiger-Meuller tube permitted me to retain the smaller .0075-uF capacitors.

Another way of improving the output regulation would be to increase the input frequency, which is what I did for an 18-kilovolt supply I built for a 6032A infrared image converter tube. This supply, shown in Fig. 4, consists of two separate supplies driven by a single source. One supply is a twenty-two-times multiplier for the 18-kV anode. The other supply is a times-four multiplier for the focus electrode. Both supplies are driven from a 600-volt, 2-kHz solid-state inverter salvaged from a damaged aircraft transponder. All of the capacitors are .002-uF/2-kV disc ceramics and each diode symbol represents two 1N4006 diodes in series.



Completed 18-kV and focus supply for an infrared viewer.

Originally, the focus voltage was derived from a resistive voltage divider across the anode supply. Using a 100-megohm resistor chain meant that the multiplier had to supply over three Watts of heat that was dissipated in the resistors! Adjusting the focus meant moving a tap, an activity I do not enjoy around an 18-kV supply. By using the second four-stage supply, I could vary the focus potential with a simple potentiometer across the input and the cost of the diodes was cheaper than the resistors.

A 116-megohm load was used as a bleeder and load for the output of the focus supply because the current drain by the focus electrode was negligible. Without this additional load, the output voltage would increase smoothly with the input, but would drop very slowly when the input was reduced. With the resistor present, the focus potential varies smoothly.

The photograph shows the completed supply. The two multiplier chains were potted to reduce losses from corona. Those who might be interested in exact design and analysis of these types of power supplies should read the excellent article by Dr. E. H. Borneman in *Electronic Design*, 7, March 29, 1978, pp. 72–74. ■

The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

CHARLESTON SC
JUL 23-24

The Charleston Hamfest will be held on July 23-24, 1983, at the Omar Shrine Temple, Charleston SC. Talk-in on 146.16/.76. For more information, call (803)-747-2324.

JACKSON WY
AUG 5-7

The 1983 ARRL Rocky Mountain Division Convention, in conjunction with the 51st WIMU Hamfest, will be held on August 5-7, 1983, at the Virginian Motel, Jackson WY. Talk-in on 146.22/.82 and .3923 kHz. For reservations, call the Virginian at (307)-733-2792. For more information, phone R. L. "Pete" Stull WB7AMP at (307)-382-9032 or Dave Gregory N7COA at (307)-875-5324.

MOBERLY MO
AUG 7

The NEMO ARC of Kirksville MO and the Tri-County ARC of Moberly MO will hold the 5th annual North Missouri Hamfest on Sunday, August 7, 1983, at the Moberly Municipal Auditorium, Moberly MO. The auditorium has 12,000 square feet of air-conditioned space for the inside flea market and there will be a limited number of tables available free. Tickets are $1.50 in advance or $2.50 at the door. Doors will open for the flea market and distributors beginning at 8:00 am and for the hamfest, from 9:00 am until 3:00 pm. There will be forums, films, sandwiches, and drinks, as well as donuts and coffee for the early birds. Talk-in on 147.69/.09. For more information and/or tickets, contact Sam Fischer KA0ILO, PO Box 341, Moberly MO 65270.

ANGOLA IN
AUG 7

The Steuben County Radio Amateurs will hold their 25th annual FM Picnic and Hamfest on Sunday, August 7, 1983, at Crooked Lake, Angola IN. Admission is $2.50. Features will include picnic-style BBQ chicken, inside tables for exhibitors and vendors, a large electronics flea market, and overnight camping (fee charged by county park). Talk-in on 146.52 and 147.81/.21.

PITTSBURGH PA
AUG 7

The 46th annual South Hill Brass-pounders and Modulators Hamfest will be held on August 7, 1983, from 9:00 am to 4:00 pm, at the South Campus of the Community College of Allegheny County, Pittsburgh PA. Tickets are $3.00 each or 2 for $5.00. Features will include computer, OSCAR, and ATV demonstrations, as well as a flea market. Talk-in on 146.13/.73 and 146.52 simplex. For further information, contact Andrew L. Plato, 1433 Schauffler Drive, W. Homestead PA 15120.

AUSTIN TX
AUG 12-14

The Austin Amateur Radio Club and the Austin Repeater Organization will sponsor Austin Summerfest '83 on August 12-14, 1983, at the Austin Marriott Hotel, Interstate 35 at Highway 290. Admission is $5.00 in advance and $6.00 at the door. Swapfest tables are available on a first-come, first-served basis, but each seller may also reserve one table in advance for $1.00. Summerfest '83 will combine the Texas VHF-FM Society Convention with forums, meetings, an indoor swapfest, dealer exhibits, and many outside activities for the family at Austin's annual Aqua Festival. Talk-in on 146.34/.94. For more information, write Austin Summerfest '83, PO Box 13473, Austin TX 78711.

DUNKIRK NY
AUG 13

The Lake Erie International Hamfest Association will hold its fifth annual Lake Erie International Hamfest on Saturday, August 13, 1983, beginning at 8:00 am, at the Chautauqua County Fairgrounds, Dunkirk NY. Admission is $2.50 in advance and $3.00 at the gate. Each flea-market space is $1.00 plus admission. There will be indoor dealer exhibits as well as a large flea market. Talk-in on 146.25/.85 and 146.52. For more information, write Lake Erie International Hamfest, PO Box 455, Dunkirk NY 14048.

POMONA CA
AUG 13

The Tri-County Amateur Radio Association will sponsor the TCARA 13th Annual Hamfest and Picnic on Saturday, August 13, 1983, from 8:00 am to 2:00 pm, at the Los Angeles County Fairgrounds in Pomona CA. Tables will be available for ham/computer exhibits and displays. There will be sandwiches and soft drinks available. For more information, contact Tony Skvarek W6ELZ, 1514 W. Mission #14, Pomona CA 91766.

BURLINGTON VT
AUG 13-14

The Burlington Amateur Radio Club will hold its annual International Hamfest and Flea Market on August 13-14, 1983, at the Old Lantern Campgrounds, Charlotte VT. For both days, tickets are $4.00, outdoor flea-market spaces are $2.00, and indoor spaces are $5.00. Food and drink will be available. Talk-in on .34/.94, .01/.61, and .52 simplex. For further information, contact Frank W1CTM, Burlington Amateur Radio Club, PO Box 312, Burlington VT 05402.

TACOMA WA
AUG 13-14

The Radio Club of Tacoma Hamfair will be held on Saturday and Sunday, August 13-14, 1983, at Olson Auditorium, Pacific Lutheran University, Tacoma WA. Events will include seminars, contests, a flea market, commercial exhibits, a dinner, and a loggers' breakfast. A 31" × 6' flea-market table is $10.00 for both days if reservation is postmarked before August 1st and $15.00 if reserved after August 1st. Dormitory and trailer spaces will be available. Talk-in on 147.28 and 224.52. For more information, contact Grace Teitzel AD7S, 701 So. 120th, Tacoma WA 98444, or phone (206)-564-8347.

HAMDEN CT
AUG 14

The seventh annual WELI/Hamden Radio Club Flea Market will be held on Sunday, August 14, 1983, from 9:00 am to 4:00 pm, rain or shine, at Radio Towers Park, Banham Street, Hamden CT. General admission is $1.00 and vendor space is $5.00. For further information, contact Darrow Loucks WA1ZWA, 199 Wayland Street, Hamden CT 06518, or call (203)-288-3765 after 6:00 pm.

GEORGETOWN KY
AUG 14

The Bluegrass Amateur Radio Society will hold the Central Kentucky ARRL Hamfest on Sunday, August 14, 1983, from 8:00 am to 5:00 pm, at Scott County High School, Longlick Road and US Route 25, Georgetown KY (off I-75/64). Tickets are $3.50 in advance and $4.00 at the gate. There is no charge for outside flea-market space. Features will include technical forums, awards, and exhibits in a/c facilities. For more information or tickets, write Edward B. Bono WA4ONE, PO Box 4411, Lexington KY 40504.

MONTGOMERYVILLE PA
AUG 14

HAM HELP

I need service manuals for the HQ-129X and Lavoie LA-261 oscilloscopes. I will pay for copies.

John Poplawski WB2GFR
9 E. 15th St.
Bayonne NJ 07002

Wanted: tuning slug or L105 coil assembly for a Collins R388. I am also looking for coil-winding information for the 20- and 40-meter plug-in coils on a pre-WWII Meissner signal shifter.

Walt Hill NM6L
Rt. 2, Box 323 Aliso Circle
Bishop CA 93514

I am looking for the schematic and manual for the Collins 75-A3 receiver. I will pay a reasonable price for the original or copies, plus all postage costs.

Donald D. Kupferschmidt WB9YYA
3004 N. 70th St.
Milwaukee WI 53210

Does anyone have the manuals or schematics for a Gonset G-76 6-80-meter transceiver and a Signal Corps BC-659 transceiver? I will pay a reasonable price for copies.

Gene Smith KA6ZAH
PO Box 240
Oroville CA 9596

I need the addresses for Jerold Antenna Corp., Galvin Antenna Corp., and Grundig Radio Corp. I also need manuals for the Eico 944, the Eico 625, the Jerold 704B TV SWR meter, the US army ME6 multimeter the US army TS-155E/UP, the B & K TV analyst 1076, and the Grundig 3165U. I have an Eico 950B manual if anyone needs it.

Kevin Nea
Rt. A Box 221
Flippin AR 7263

I am looking for modifications for the Davco DR-30 receiver. I would also like to purchase any Davco receivers, speakers or power supplies in any condition.

Michael Crestohl VE2FW
PO Box 64
Victoria Station
Montreal, Quebec
Canada H3Z 2Y7

I need schematics for the following: KIN TEL model 301 voltage standard; RT-66 transceiver; BC-983-A VHF/UHF radio modulator; BC-638-A frequency meter with type 5004 monitor crystal; Nems-Clarke noise-factor measurement unit, type NTS-200; and Hickok VTVM, Navy Model OBQ-1.

John C. White WB6BLV
560 North Indiana
Porterville CA 93257

I am trying to find any kind of information, including the manual, schematic, or even old ads, for the Hallicrafters FPM 200 transceiver. It is a solid-state rig made around 1959-60.

Hans Zimmermann HB9AQS
PO Box 5C

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

A small group of Limassol amateurs is trying to organize a club station and attract young people to the hobby, but our own means are not sufficient to do so. We are making an appeal to amateurs worldwide for help, either in equipment or funds.

Aris Kaponides 5B4JE

Route 3, Box 97
Rocky Mount NC 27801

I'm looking for operation and maintenance manuals for the following military-surplus signal generators: TS-418/URM-49 (400 MHz to 1000 MHz) and TS-510A/USM-44A (10 MHz to 420 MHz). I will copy and return the manuals or pay a reasonable amount for your copying expenses.

Bruce A. Rahn WB9ANQ
410 Coronado Trail
Enon OH 45323

I need information on the PLL of the Icom 22. My unit drifts out of lock and returns, apparently from a thermal intermittent. I am also seeking any information on redesigning the 22 for band expansions. Finally, does anyone have an EPROM substitute for the diode board?

I will gladly pay for copying or mailing costs.

Robert Palmer

520 Palm Springs Blvd.
Indian Harbour Beach FL 32937

I have a Pickering Radio Company model KB-1 CW keyboard, serial number 182. It works well except it makes a J when I press the Ø key. I do not have a schematic of the unit. Can someone help me?

John A. Barolet KJ3E
108 Elliott Court
California MD 20619

I need a schematic, power plug, and any information on a KLM 10-160BL 2-meter amplifier.

Tom Norris KA4RKT

Auburn KY 42206

CORRECTIONS

"Unleash the TS-900," which appeared on page 10 of the February, 1983 issue, should have been titled "Unleash the TS-9000"; in addition, Q8 in Fig. 4 was drawn with the collector and emitter leads reversed.

Avery L. Jenkins WB8JLG
***73* Staff**

On page 87 of the July issue, in "Down-Under Depth Sounder," the construction notes said that pins 8 and 16 of IC4 and IC5 should be soldered to the board last. Actually, these supply pins should be soldered first.

The Spider™ Antenna

The modern multi-band mobile antenna —switch to 10, 15, 20 or 40 meters without stopping to change resonators.

Features of the Spider™ Antenna

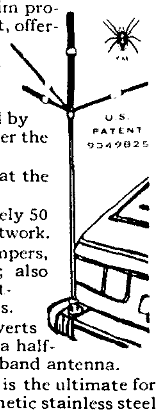
• The Spider™ Antenna is less than six feet high and the longest resonator projects out from the mast 24 inches. This gives a slim profile, low height and light weight, offering little wind resistance and eliminating the need for a spring mount.

• Each resonator is tuned to the desired portion of the band by a tuning sleeve which slides over the outside of the resonator.

• SWR is approximaterly 1:1 at the selected resonant frequency.

• Base impedance approximately 50 ohms, requiring no matching network.

• Ideal for use on vans, campers, motor homes, travel trailers; also in mobile home parks, apartment houses and condominiums.



The Spider™ Adapter converts any mono-band antenna with a half-inch mast into a modern four-band antenna.

The Spider™ Maritimer™ is the ultimate for marine use. Made of non-magnetic stainless steel and nickel-chrome plated bronze, using regular Spider™ resonators and tuning sleeves.

Accessories—Bumper, ball, angle and stud mounts. Quick disconnects. RG-58A/U coaxial cable and connectors. Ground radial systems. Copper foil and copper braid ground straps.

HOT ROD ANTENNA

Achieve 1 or 2 db gain over ANY ⅝ wave two meter telescopic antenna. The AEA model HR-1 Hot Rod™ antenna was designed by Dr. D.K. Reynolds (designer of the IsoPole) to deliver maximum performance for any hand-held transceiver with a BNC fitting.

The factory-tuned HR-1 is 20% shorter, lighter and places far less stress on your hand-held connector and case. It will easily handle over 25 watts of power, making it an excellent emergency base or mobile antenna. In the collapsed position, the Hot Rod antenna will perform like a helical quarter wave.

The Hot Rod antennas can be expected to make the same improvement to hand-held communications that the IsoPole brand antennas have made to base station operations. Why pay more when the best costs less?

Prices and Specifications subject to change without notice or obligation.

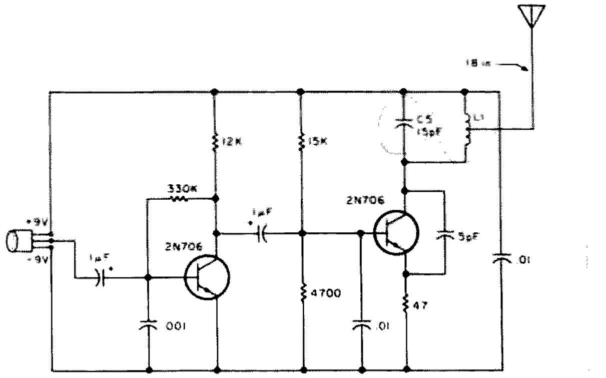
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73 Magazine, Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*

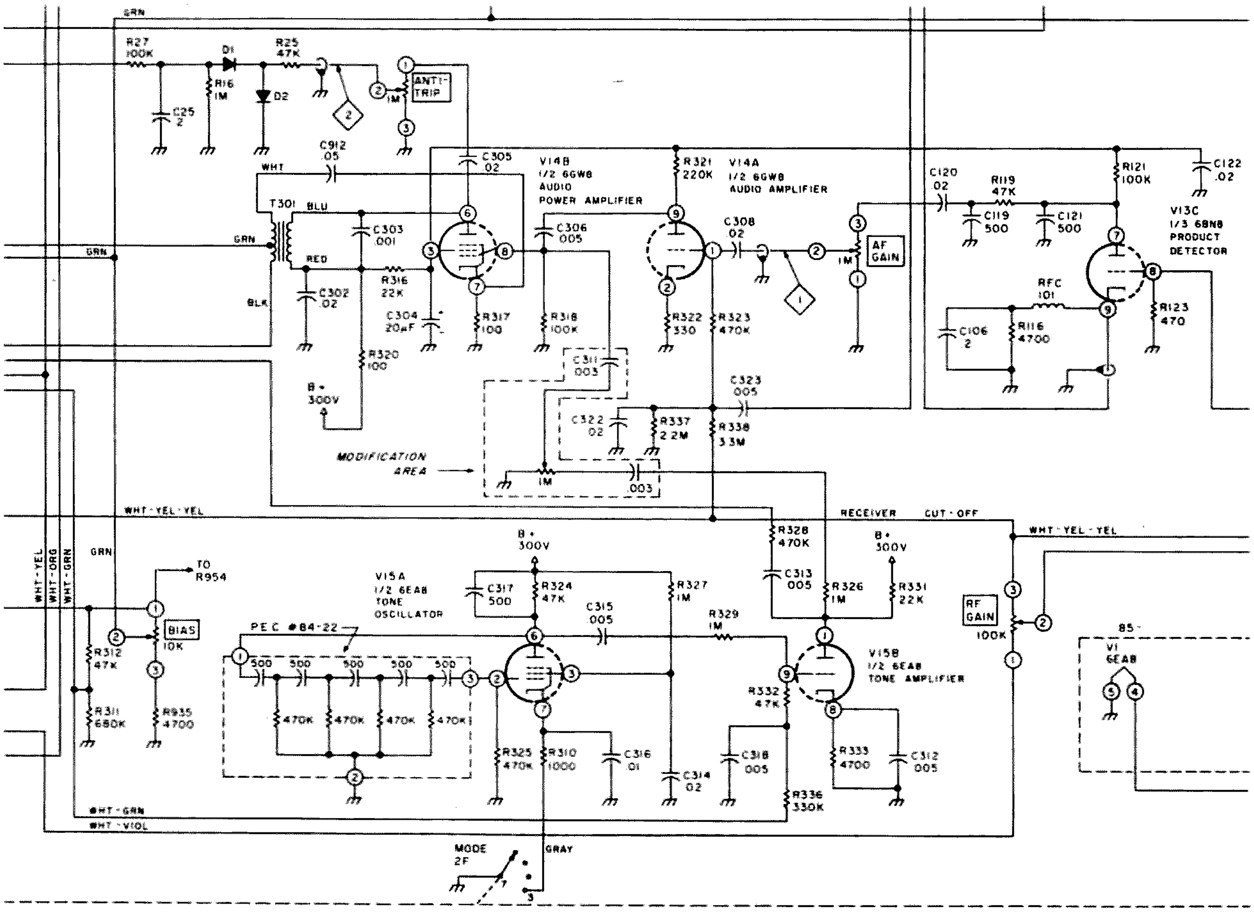
WARPING ZENER VOLTAGES TO AN EXACT VALUE: Most people think of a zener diode as being a fixed reference voltage, perhaps containing some tolerance around the nominal voltage, but fixed nonetheless. In fact, a zener's voltage is rather dependent upon the current flowing through it. By varying the zener current, the reference voltage can usually be varied by about 10 percent. For example, a nominal 12-V, 1-W zener diode (1N4742) can be set to any voltage between about 11.5 and 12.5 V. Thus, by using a combination of zener and potentiometer, a very precise reference voltage can be obtained. However, this is a relatively high impedance source and loading will change the zener voltage.—Craig Crichton K7UKW, The Dalles OR.



SIMPLE FM TRANSMITTER: This transmitter can be tuned to the FM broadcast band, 2 meters, or other VHF bands by changing C5 and L1. The values given for C5 and L1 will place the frequency somewhere in the FM broadcast band. L1 is 4 turns of #20 enameled wire airwound, ¼ inch in diameter, 5mm long, and center-tapped. The microphone is an electret type and the antenna is 18 inches of any type of wire. Keep all leads as short as possible to minimize stray capacitance. The range of the transmitter is several hundred yards.—James Kretzschmar N4HCJ, Huntsville AL.

MEMORY POWER SUPPLY FOR THE ICOM IC-720A: The IC-720A memory for both vfo's can be powered by the Radio Shack 9-V-dc Battery Eliminator (cat. no. 270-1552). To interface the supply to the rig, cut off the snap connector of the Battery Eliminator and replace it with a phono plug with the positive lead going to the center conductor of the plug.—Charles Hall N4ESJ, Sterling VA.

VARIABLE SIDETONE FOR THE HW-101: This circuit adds a separate volume control for the 101's CW sidetone. Remove C311 and use the mounting holes to connect the additional components to the board. The value of the capacitors is not critical; any combination between .002 and .005 uF should work.—Vernon Henry, Manchester NH.



W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

recorder is opening up the unwanted television transmitting hours to prime-time watching via delayed viewing, we amateurs might start thinking in terms of sending messages to friends rather than actually talking with them. Our soon-to-come satellite will work this way. We'll send a message to it which will be stored and then, as the satellite circles over Bangkok, say, it can be dumped upon demand.

The cost and bother of writing letters is a limiting factor, but if we could keep in touch every day or so with a hundred friends via amateur radio messages, messages which would be delivered error-free and without fail, I wonder how we would look at our hobby. The DXpedition in Burma could be reached via messages which would be queued up for them, each then answered and confirmed.

Or perhaps you're willing to fight to death to keep amateur radio the way it is today... virtually unchanged in the last 50 years. I've enjoyed what we've had, but I'm looking for change ... for faster, surer communications. I'd love to swap messages with old friends... Eddie W2OCL, Frankie W2OCM, good old Walt W2LBF, Frank W6AOA, Reg W6ITH... old ham friends from places where I've lived, such as Sarasota, Hampton, Brooklyn, Troy, Dallas, Cleveland... hams from countries I've visited all around the world. It's a real bear finding Paul 9M8PW on the bands in the few minutes a week I have available, yet I'd like to keep in touch without the dollar or so postage and three weeks for airmail to Borneo.

We'll see what comes of the latest FCC effort toward deregulation. I'm certainly behind them 100% on this one.

POTENTIAL GROWTH

Should my modest concept of having a ham club in every school in the country come about (and I think it can be swung), there is going to be some demand from this program for assistance from existing ham clubs... a need for information to help faculty advisors cope and a need for beginner-type study courses.

For starters, I'd like to devote at least a page of *73* each month to a message of inspiration for potential club members, something which might be posted on the bulletin boards of schools along with meeting notices. You can help with this. You can help a lot, actually. Sure, I can write little messages telling about the fun I've had in amateur radio, but I'm just one of over a million hams around the world, so every possible experience I've had has been eclipsed a hundred or thousand times over... if you'll think about it and write.

I'd like to have some of your stories telling us why you enjoy amateur radio. I'd like to hear about some of the things which have been exciting to you about the hobby. I'd like to hear how it may have helped you in some way. I know that ham radio saved my life once and the lives of a whole bunch of my friends. There are stories in every ham... and some of them are very exciting. Let's get them told and see if we can use the enthusiasm that you and I have built up for this wonderful hobby to spark interest in yet another generation of hams. We need them.

There are fascinating stories of DXpeditions, of moonbounce operations, of contest operations, of getting medicine to some remote spot of the world to save a life, of rescue at sea... and all of these can be translated into what are almost typical personal experiences as examples of what amateur radio has to offer the newcomer.

Sure, I can write about those bitter cold nights on top of the local mountain, Mt. Monadnock, trying to establish contact with WA1KPS with an experimental 10.5-GHz transceiver. I had to have it pointed in exactly the right direction and be tuned to exactly the right frequency at the right time to make it go. I stood there in the cold framework of a fire tower with the wind whipping me into numbness, holding onto the transceiver so the wind wouldn't whip it off into the night and aiming its little horn antenna hopefully in the right direction, a flashlight cradled by my head against my neck to light up the dials. I'm not sure why such misery is fun, but it sure is.

I remember the night when I was on my first DXpedition. We were sailing toward Navassa Island from the Bahamas and were in the grips of a fierce storm. It was pitch black and the ship was rolling almost beyond recovery every now and then. I'd been on watch all night because no one had dared to try to get up to the bridge in the storm. The captain was there, convinced that the black mass looming ahead was just another inky cloud, while I was sure it must be land. Just moments before we would have crashed on a reef offshore of the island, I spotted a small light, convincing the captain that perhaps it was not a cloud.

Then there's the time two other hams on a trip with me came within minutes of being killed by the Shifta tribesmen of Somalia when we were driving in the great Rift Valley in the Kenya desert. But was that any more exciting than sitting in Puerto Rico and hearing ham signals bouncing off the moon on 1200 MHz from all around the world... and working them?

Your stories don't have to be dramatic; we just want to know what it is about amateur radio that makes it such an important part of your life. My own life is riddled with it. So, probably, is yours. What gets you? Is it traffic handling? Contests? Certificates? Outdoing others with over-the-air filth? Jamming repeaters? DXing? Eyeball nets? Hamfests? Dig down in your memories and give me the material to fire the imaginations of a million kids... two million. And please double-space it, okay?

JOBS AND CAREERS

Back in 1960, one of the kindest people to me that year was the publisher of *CQ* who fired me. I was at a loss for a few months, looking around for what to do next. I tried an ad agency and hated it. The idea for a new ham magazine devoted to building small construction projects was eating at me, but it takes a bundle of money to start a magazine and I had no big bundle.

Efforts at firing the enthusiasm of a couple of hams with money came to naught. So, despite my involvement with putting on a Hudson Amateur Radio Council convention in New York, getting Mensa started, being involved deeply with car rallies as president of the Porsche Club, and so on, I decided what the hell and got *73 Magazine* going. The work started in May and the first issue came out in October. Fortunately, it was in the black and the long haul toward success was started. I'd sold off everything I could to get things going... my boat, plane, horse, one of my Porsches—anything which would bring in some money.

Just as the magazine was really getting going (in 1963), the "Incentive Licensing" debacle hit and within a couple of years 80% of the ham dealers in the country were out of business, taking away both the counter sales of the magazine and a lot of advertising. Then virtually every major manufacturer went either out of business or into something else. We got down to about five people to survive those hard years.

It wasn't until around 1970 and my discovery of FM and repeaters that things began to turn around. By publishing hundreds of articles, organizing FM symposiums, putting out a dozen or so books on FM and repeaters (even a special *Repeater Bulletin*), I began to build up interest in this activity. *QST*, *CQ*, and *Ham Radio* either fought me or were indifferent to FM, so I got no help from them.

By 1975, we were finally in fairly good shape, despite a hard battle with the IRS over expenses of ten years previous. This was when we started *Byte*... only to have it disappear in the middle of the night after a few months of getting an incredible start. Bent, but not stopped, as they say, we worked hard to pay off the mountain of bills left by *Byte* when the magazine left, taking its fat bank account with it. As soon as we could, we started *Kilobaud Microcomputing*, which took off fine. That was in January, 1977. In 1978, we started our Instant

Software division with one technician working out of the potato cellar. That grew to where we had to get a whole building for it. . .our Elm Street building.

By 1980, we'd seen the growth of the TRS-80 and figured that we'd try something new: a system-specific magazine (*80 Micro*). It was a first and started off with 132 pages. By the end of the first year, it was up over 400 pages!

By late 1981, we were able to get *Desktop Computing*, a magazine in plain English for the businessman, going. And then a year later, *inCider*, our Apple magazine, was up and running, following the same successful path of *80 Micro*.

All this meant more people, more buildings, and a development of our management team. Almost everyone coming into Wayne Green Inc. started out from the bottom, learning from those already here and then working on up into management.

Now the growth is picking up. This month we started *Hot CoCo* for the Radio Shack Color Computer, and we have a growing number of new publications in the planning stages. We're even thinking of getting into a new-magazine-a-month mode by next year!

There are plans for developing a college, a combination high tech and business college. We're working toward a possible television station. We're going to be expanding our book department substantially. . . and so on. All this means, of course, that we're going to be needing a lot more people to help with the growth.

At present, we have about 250 people. In a year, I think we'll be running about double this. . . and double again within another year. This means that we have an awful lot of good hot career spots open for people interested in working in magazine publishing, education, graphic arts, data processing, writing, editing, technician work, programming, sales, marketing, sales force managing, circulation, writing up new products, and so on. No, we don't have a lot of spots for top management. We're both lean on management and primarily interested in developing managers from our own ranks so they will know what we're doing and how it all fits together. Oh, we'll be needing some experienced people to help get completely new projects going.

While most of our development will be in New Hampshire, we are going to test out an idea in Boston and see if it flies. If so, we may be looking for teams in every major city around the country to work on similar projects. And if the pilot project college is a success, can there be college franchises?

One of the best things about our success has been the fun involved. The people working here have been having a fantastic time. Ideas are constantly springing up for new divisions of the business. . .new publications. . .promotions.

So, if you're looking for a career, what we're doing up here in New Hampshire may be what you're looking for. You can't find a better place in the country to live and work. No, we still don't hire smokers, so our air is crystal clean. Even if you've quit smoking *recently*, please don't call, okay? We want people who are not addicted to drugs. . . even tobacco. We have beauty in our mountains, the lowest taxes in the country, surprisingly low-cost housing, and a quality of life that California only wishes it could provide.

Readers with small high-tech firms should start thinking in terms of an eventual move to New Hampshire. I'm aiming at starting a high-tech industrial complex which will have a good low-cost pool of high-tech youngsters available to work at product design, production, programming, sales, and so on. You'll have a chance, once we get going, to get the cream of the country's brains, helping them to train for life and getting their enthusiasm at bargain rates.

Keep thinking about this. I'll have more news as we move ahead.

WWII FINAL BATTLE WON!

A card from Joe Vegh W5VSV of Corpus Christi put things into an interesting perspective. He says, "Dear Wayne: Sorry about your undying love affair with the Nipponese! I'll straighten screws, glue on decals, touch up paint, and complain like hell to the manufacturer, but I will not knowingly buy Nipponese products unless there is no other choice *and I need* the products. It is a sorry thought indeed that our government purchases products from a nation which caused us so much pain! The final battle of WWII is now in progress!"

Amen! Yessir, I got to thinking about Joe's position on this and as a veteran of WWII, I can see where he's coming from. Those Nipponese worked hard and long to try to kill me during the war, and they did manage to polish off about 20% of my shipmates in American submarines. When I look back at the trouble the Japanese caused (and the Germans and the Italians), why, it makes my blood boil.

And just a generation earlier, those Germans, along with the Austrians, Hungarians, and so on, were out there killing my parents' friends. These are things that we probably should not forget when we are shopping and thinking in terms of a Porsche car or even a German meal. But that isn't the end of it by any means, because when I look back in my genealogy books, I find that a surprising number of my ancestors were being fought by the British in the revolution. I wish I'd thought of that when I was shopping for a Jaguar car a couple years ago. Those English scoundrels killed tens of thousands of pioneer Americans.

And what about the rebs in the Civil War? You can bet that the next time I see a southern fried chicken franchise I am going to turn and head the other way. Just think of the thousands upon thousands of Yankee youngsters that were slaughtered by the rebels!

And how many of you have forgotten the Alamo? Should we casually forget the brutal killing of our patriots in San Antonio. . .and not all that long ago, either? I'll bet that if Joe thinks about it, he'll be right out there on the Rio Grande with a machine gun wiping out the wetbacks who are infiltrating our country and taking away the low-paying jobs from our inner city illiterates.

Perhaps we should think more in terms of blacklisting businesses who consort with our known enemies. We're already doing this to some extent with firms who are doing business in South Africa, and they haven't even fought a war against us yet! The Arabs have blacklisted firms doing business with Israel, such as Coca Cola; you get Pepsi in most Arab countries. Well, I want you to remember the next time you see a McDonald's that they have branches in Germany, Italy, Japan, Britain, and so on. The same goes for the southern fried chicken chain.

The brutal fact is, if you look at it, that about the only major country in the world we haven't had a war with is Russia. That's something to think about when you are looking to see where your real friends are, isn't it? You know, thinking about that, the fuss over the huge American military budget (which is mostly to threaten Russia), and the growing groups against nuclear weapons, perhaps we could make everyone happy with one simple change. I know this is a daring thought, but it seems to be the direction that the nuclear opponents and disarmament groups are headed—what if we just turned America over to Russia?

With the US and the USSR together, we could take over every other country in the world in a couple of years, setting up a real world government. Then, without the need for military spending by *any* country and an end to coups in the erstwhile Third-World countries, we could all work toward getting enough food to feed everyone.

We hear a lot about Hitler killing twelve million people during the war, but we don't hear so much about the even greater number that Stalin wiped out to consolidate his power. With such ruthless control from Moscow, we might see countries like India cut back in population to a more controllable number. The Russians have managed to get used to communist rule and the slave labor camps that go with it, so we probably could, too. I'm sure that many people would prefer that problem to a nuclear war. . .right? Heck, we have people ready to die to fight nuclear power plants!

Without the need to support a monster military-industrial complex, I'll bet we could most of us go back to farming, cultivating a small plot of land and taking it easy. We wouldn't have to work so hard to support the government bureaucrats. . .which is taking over one third of our work these days, as I recall. We could get rid of our computers, most of our telephones, throw out the television, and go back to

the simple life of a hundred years ago.

Isn't it interesting what creative thoughts a new point of view can generate?

SCI-FUN

With the awakening interest in science, there may be an opportunity for all you ex-science teachers who have gone on to greater earnings in industry to reap some benefits. Just because you are making a lot better living in the electronics industry doesn't mean that you can't still teach. . . and make more than ever.

My utopian view of the ideal teaching system encompasses the concept of learning being fun. It has to do with people learning under their own steam instead of the system I grew up under: slavery. Yep, I'm looking forward to the emancipation of kids. I *had* to go to school every day. It was the law. There was no free will about it.

Now that there seems to be a sprinkling of parents who are becoming aware that educators have been going with the flow, making more and more of our government-run educational system plain vanilla, perhaps it is time for an alternate approach, at least as far as science education is concerned. I have the concept for a series of books which would make science fun. . . not only for kids, but for anyone interested in taking a few hours away from Monday Night Football, M*A*S*H reruns, and other prime-time garbage which lines our way from the crib to the coffin.

If you think you're a good enough writer to put together a book which will cover some particular aspect of science and do it in both an entertaining and informative way, start outlining what you have in mind, write a first chapter, and let's see if we might be in business.

THE AGONY OF DEFEET

In amongst all of the usual bad news (which must sure be popular since there is so much of it) was a news flash of particular interest to me. It had to do with a recent medical breakthrough to the effect that flat feet are now being considered as normal.

When I was young, having flat feet was on a par with the heartbreak of psoriasis. I had 'em. I mean that my footprint in the locker room coming out of the shower was square. I had no detectable arch at all. Well, I suppose the flat feet went well with my knock knees.

Those damned arch-support shoes may be okay for people with weak arches, but they are terrible for people with perfectly good, though flat, arches. The foot experts did everything they could to get my flat bones to arch, adding a good deal of extra pain to my already painful teen years.

When I was twenty, the government decided that there really was not going to be any way to bring the great war to a successful conclusion without my full cooperation. They reasoned with me about this with draft notices, but I escaped death in the trenches by joining the Navy. Well, with flat feet I figured I probably could swim better than I could walk.

Already being a ham at the time, I opted for their radio technician training, which turned out to be incredibly good, truly an anomaly for the government. After nine months of this training, it was time to go into the fleet. Since I'd have the best chance to be my own boss on either a submarine or a destroyer, the extra pay and the special food you get on submarines swung it that way. I volunteered.

They have a tough physical for the submarine service. I was sent down to be checked out. I sat there with all the others, memorizing the eye chart. But when it came my turn, they said "too fat; next."

Not to be dumped out of submarines that easily, I pressed them. How much overweight was I really? They grudgingly looked it up and said I was eight pounds overweight. This was Friday, so I asked if I came back Monday eight pounds lighter I'd pass. Sure.

Early Saturday morning, I was out on the grinder running. I then went over the damned obstacle course four times. Then I changed into my liberty clothes and headed for San Francisco, where I walked miles, ending up at a steam bath. I steamed for hours, the sweat pouring off.

By Monday morning, I was almost totally exhausted. I'd had nothing to eat since Friday and hardly anything to drink. I dragged myself into the sick bay examination room and presented myself for weigh-in. Sure enough, I was ten pounds lighter! The doctor was not terribly impressed. He took another look at me and said, "You're disqualified for submarine duty because you have flat feet."

I was furious as well as incredibly tired as I staggered back to the school. When I got there, they asked me if I'd passed the submarine physical. I said sure, and that was that. As the depth charges dropped around us off the coast of Japan, I looked at my medical records where it was clearly stamped in red: DISQUALIFIED FOR SUBMARINE DUTY.

DX

Santa Rosa CA 95402

The Cheynes II, *a former whaling tender, carried the Heard Island DX Association 15-member team to and from Heard Island.*

THE HEARD ISLAND STORY

This year, DXers have enjoyed not one but two successful DXpeditions to tiny, frozen Heard Island in the southern Indian Ocean. The "Heard Island Expedition" won the race to Heard (see this column, January, 1983) with VK6FS first in the VKØCW logbook on January 22. Jim Smith's "Heard Island DX Association" group arrived soon thereafter, and for a few days, DXers worldwide had a choice of Heard Island stations to call. Despite poor band conditions, by the time bad weather forced the two groups off Heard, DXers had made about 45,000 QSOs with the DXpeditioners.

A few months later, the primary operators of both Heard Island DXpeditions met at the International DX Convention in Visalia, California, and at the Dayton Hamvention in Ohio in April.

Al Fischer K8CW Heard Island Expedition

On the last day of December, 1982, the Heard Island Expedition departed Perth in western Australia for Heard. For two and a half weeks the expedition yacht, the *Anaconda II*, battled the winds and seas of the notorious southern Indian Ocean before making landfall at Kerguelen Island, about 300 miles north of Heard. The winds blew out 25 sails during the passage, and the DXpedition generators got a good workout supplying electricity to the sewing machines repairing ripped sails. Any expedition member venturing out on deck kept a safety line firmly attached to the boat, as the rough seas made falling overboard an ever-present concern.

The *Anaconda II* reached the comparative calm of Atlas Cove on Heard Island on January 21, but the amateur radio operators learned that the old radio towers hadn't survived the last winter. The DXpeditioners appropriated one of the best-preserved of the numerous shacks abandoned 30 years ago. The tribander and vertical went up, the Icom transceivers were connected up to the amp supply linears, and VKØCW went on the air.

At first, Al couldn't raise a pileup from Heard. Simultaneous pileups on Chad, China, and others made DXers overlook the comparatively weak signal out of the Indian Ocean. Al finally got the contacts rolling, however, and, with the help of Dave VK3DHF, made more than 30,000 contacts in the next month.

The Icoms survived the harsh environment faultlessly, and even the tribander outlasted all but the strongest winds. Unfortunately, propagation on the higher bands was poor. 20 and 40 meters provided most of the contacts, and a beacon on 6 meters went unanswered the entire trip. Al found California DXers hardest to work, since the radio path to California passed directly over Europe, and he couldn't get European DXers to stand by during the short propagation window to W6.

The stay on the island was not without its hazards. A constant wind blew fine vol-

canic sand into everything: sleeping bags, food, clothing. It was so cold that Al left the amp supply linears on all the time, for warmth, even though Australian regulations prohibit the use of linears on CW. The DXpeditioners also provided communications for the mountaineering group tackling Heard's volcanic peak, Big Ben. This short-range communication task forced the amateurs off the DX bands during some of their best propagation, as the generators had to be turned off. Perhaps worst of all, the amateurs had only 2 cases of beer to last 6 weeks!

Between stints at the radio, the DXpeditioners assisted some of the scientists on the expedition with their research. Since the largest plant life of the island is no bigger than a cabbage, scientific interest centered on an abundant bird population and the colonies of elephant seals. So when Al wasn't handing out Heard Island contacts, he was chasing (and tackling!) penguins for blood samples!

VK0CW lost the triband beam in a hurricane, but it was a tribute to the advance planning that the expedition had so little trouble. The tribander was equipped with newly-machined parts, since regular hardware would have had little chance against Heard's hostile climate. The expeditioners even spent a night in a deep freeze in Australia, testing their tents and sleeping bags against the anticipated harsh weather.

Jim Smith VK9NS—
The Heard Island DX Association

Meanwhile, Jim Smith's group was having transportation problems. Their chartered ship, the *Cheynes II*, had to put back into port twice, putting the group behind schedule. By the time the 15 members of the Heard Island DX Association DXpedition landed on Heard, the Heard Island Expedition had been on the air for more than a week. And this was just the start of Jim's troubles.

The first group grabbed the best of a sorry lot of abandoned shacks at the Atlas Cove landing site. Jim Smith's group had to set up shop as far away as possible, to avoid mutual interference, but the remaining shacks were uninsulated and doorless. The hard ground made driving guy stakes almost impossible, and their Minooka Special didn't even last the first night. The 3-element monobanders for 10 and 15 were useless, with the low maximum usable frequencies. Intermod problems between the two DXpedition stations, less than a half-mile apart, kept the two groups from operating 20 meters at the same time. At times, Heard Island transmitters sat idle, with no one calling!

Weather conditions went from bad to worse on Heard. The barometer plummeted as a hurricane lashed across the island. The Heard Island Expedition, whose mountaineering team had reached the top of Big Ben, packed up their gear and boarded their ship for the sail back to Australia. The high winds and waves forced the *Cheynes II* to fire up its boilers, to avoid being dragged onto the rocks. But the *Cheynes II* was critically short on fuel from its long, upwind trip to Heard. So once the engines were started, the Heard Island DX Association group was forced to curtail operation, leaving Heard after only 14,000 contacts. But the storm did further damage. *Cheynes II*'s motor launch, used to ferry personnel and equipment between ship and shore, sank in the heavy seas. The Heard Island DX Association mountaineering team, thwarted in their attempt to climb Big Ben by, of all things, too warm weather (4-5 degrees Celsius—about 40° F.), was trapped on the other end of Heard, with no way to get to the *Cheynes II*. The *Anaconda II* loaned their inflated Zodiac tender to rescue the stranded climbers.

Even the return trip was not the easy downwind sail predicted. The *Cheynes II* was so low on fuel by this time that they "sailed" most of the way back to Australia. "Drifted" might be a more accurate description of the process, as sheets and tarps were fashioned into makeshift sails for the mastless vessel. A mid-ocean rendezvous and refueling helped the *Cheynes II* limp home from its odyssey.

Between them, the two DXpeditions did an excellent job of satisfying the DX demand for Heard, even though the poor propagation kept the total number of contacts low and frustrated those DXers looking for 5-band contacts. And the 6-meter beacon went unheard the entire trip. On the plus side, Kirsti Smith, Jim's wife, was the first YL operator on Heard, under her own VK0NL callsign. Jim's group also made the first RTTY and satellite contacts from Heard Island.

But even as Jim returned to Norfolk Island with his wife, and Al Fischer was reunited with his new bride, the Heard Island 1983 saga continued.

Rumors and accusations filled the airways and DX bulletins and carried over to the personal presentations at the conventions. Did the amateur community "buy" seats on the Heard Island Expedition for too much money? Was the *Cheynes II* really properly fueled and equipped for the voyage? It is unfortunate that such bitter aftereffects should mar two fine DXpeditions.

The final chapter of the Heard Island DXpeditions has not yet been written. Both groups invested a great deal of money to bring Heard Island onto the amateur bands, and both hope to recoup some of those funds now.

QSLs: If you were one of the lucky ones who worked Heard, you should have your QSL card by now. If not, try another card to N2DT for North American contacts with VK0CW and VK0HI, or via Box 90 Norfolk Island, South Pacific 2899, for VK0JS and VK0NL contacts. Jim Smith got his QSL cards out quickly and included a pitch for membership in the Heard Island DX Association Club.

Finances: Whether you worked Heard or not, you have to admire the courage and dedication of the operators of both groups. "Frozen Fingers" Al Fischer interrupted his honeymoon to leave for Heard, and he endured weeks at sea, terrible weather, and hostile penguins to help you work Heard. He figures his personal costs for the trip at over $10,000.

Meanwhile, Jim Smith is selling philatelic covers from the Heard trip to help cover the more than $23,000 he advanced the HIDXA for the trip, and to help pay for the *next* DXpedition by this active amateur.

If you haven't made a contribution, no matter how small, to one or more of the sponsoring groups, by all means do so now. Your membership in one of the three DX organizations involved in the Heard DXpeditions will encourage other operations of this type.

In a few months the promised slide, movie, and videotape presentations should be out, and DXers around the world will be able to share in some of the excitement of a major DXpedition. And it seems unlikely that there will ever again be two different stations simultaneously active from Heard Island.

(For an insider's view of the HIDXA DXpedition to Heard Island, see "The True Story Behind Heard Island," *73*, July, 1983, page 20.—Ed.)

Jim Smith VK9NS, organizer and chief operator of the VK0JS Heard Island DX Association DXpedition, spoke at the International DX Convention in Visalia CA.

PILEUP BUSTING—BY THE EXPERTS

At the International DX Convention in Visalia, California, in April, program chairman Jay O'Brien W6GO moderated a panel of top DXpeditioners on the topic of busting pileups. Members of the panel have made hundreds of thousands of contacts over many years of DXpeditioning. Here are their suggestions of ways to get through the calling horde:

Eric Sjolund SM0AGD: "How do I break pileups? I gave that up ten years ago; it's so much easier to be on the other end of the pileups! Seriously, first listen to the pileup: where is the DX station listening? Don't stay on the same frequency; keep moving around. If the pileup is especially heavy, move to the edge of the crowd. Send your complete callsign once, then listen, don't send just the suffix, as that takes too much time. On SSB, use proper phonetics, not crazy, cute, or geographic phonetics. When I work split I'll suddenly change my listening frequency and announce it once. If you're listening, you can catch me quickly."

Al Fischer K8CW: "Listen first, to determine the DX station's listening frequency. I use wide splits to eliminate calls from transceiver-equipped stations. I usually work the loudest station first, a plus for DXers with large antenna farms. Finally, when the DX station asks for the station with the 'N,' stations without an 'N' in their call had better stop sending. I maintained a blacklist of poor operators on the cover of the logbook; they won't get QSLs!"

Jim Neiger N6TJ: "Listen to the pattern of the operator: who does he come back to? Avoid sending just your suffix; having to go back to confirm the rest of the callsign is too slow. Don't get into a shouting match with a rival; neither of you will work the DX station. If you can do it on CW, you can do it on phone; CW is where it's at!"

Fred Laun K3ZO: "On CW, tune down from the top of the pileup. Find the last station worked, and move a little lower for your call. On SSB, count to 3 after the DX station says 'QRZ,' to give the pileup a chance to thin out a little. If you are transmitting more than 10 seconds at a time, you're doing something wrong. Don't say 'QRP'; send your call. If the DX station can hear your 'QRP,' he can hear your callsign."

Jim Smith VK9NS: "Don't send just your suffix. I write logs left to right, and you don't want to go into the log backwards. I listen for the weaker signals as well as the strong ones, but don't spread the pileup out too much. As I use push-to-talk, I hear the tailenders. Familiar calls are easier to recognize, so being active on the DX bands helps break pileups."

Iris Colvin W6QL: "Listen to the DX station, especially instructions such as listening frequency; working by call areas, etc. If you're not getting through, try something different."

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

NEW JERSEY QSO PARTY
2000 GMT August 13 to 0700 GMT August 14
1300 GMT August 14 to 0200 GMT August 15

The Englewood ARA invites all amateurs worldwide to participate in the 24th annual NJ QSO Party. Phone and CW are considered the same contest. A station may be contacted once on each band. Phone and CW are considered separate "bands" but CW contacts may not be made in phone band segments. NJ stations may work other NJ stations.

EXCHANGE:

QSO number, RS(T), and ARRL section, country, or NJ county.

FREQUENCIES:

1810, 3535, 3900, 7035, 7135, 7235, 14035, 14280, 21100, 21355, 28100, 28610, 50-50.5, and 144-146. Suggest phone activity on the even hours; 15 meters on the odd hours (1500 to 2100 GMT); 160 meters at 0500 GMT.

SCORING:

Out-of-state stations multiply the number of complete contacts with NJ stations by the number of NJ counties worked (21 maximum). NJ stations count 1 point per W/K/VE/VO QSO and 3 points per DX QSO. Multiply total QSO points by the number of ARRL sections (including NNJ and SNJ—maximum, 74). KP4, KH6, KL7, etc., count as 3-point DX contacts and as section multipliers.

AWARDS:

Certificates will be awarded to the first-place station in each NJ county, ARRL section, and country. In addition, a second-place certificate will be awarded when 4 or more logs are received. Novice and Technician certificates will also be awarded.

ENTRIES:

Logs must show date/time in GMT, band, and emission. Logs must be received not later than September 10th. The first contact for each claimed multiplier must be indicated and numbered and a checklist of contacts and multipliers should be included. Multi-operator stations should be noted and calls of participating operators listed. Logs and comments should be sent to: Englewood Amateur Radio Assoc., Inc., Post Office Box 528, Englewood NJ 07631.

A #10 SASE should be included for results. Stations planning active participation in NJ are requested to advise the EARA by August 1st of their intentions so that they can plan for full coverage from all counties. Portable and mobile operation is encouraged.

NEW MEXICO QSO PARTY
Starts: 1800 GMT August 20
Ends: 2100 GMT August 21

Sponsored by the Albuquerque DX Association. Work stations once per band and mode. Repeat QSOs are allowable for credit only if the NM station changes counties. NM stations operating on county lines count as a single QSO, but multiplier credit is allowed the non-NM station for both counties. Use all amateur bands except 30 meters. Repeater QSOs are not allowed. Entry categories include both single and multi-operator, regardless of whether operating fixed, portable, or mobile.

EXCHANGE:

Phone—1835, 3985, 7230, 14280, 21370, 28570, and 147.51. CW—1805 and 60 kHz up from low end. Novice—25 kHz up from low end.

SCORING:

Count 2 points for each phone QSO and 3 points for each CW QSO. NM stations multiply total QSO points by total number of NM counties, states, provinces, and DX countries worked. All others multiply total QSO points by the total number of NM counties worked (33 maximum).

AWARDS:

Plaques will be presented to the top-scoring NM stations, the highest-scoring non-NM station in each entry category, and the highest-scoring NM club with 3 or more members submitting scores. Certificates will be awarded to the top scorers from each NM county, state, province, and DX country in each entry category. A special certificate will be awarded the highest-scoring NM mobile or portable station.

ENTRIES:

Entries must be postmarked no later than October 1st and addressed to: Ed Graham N5HH, 12449 Regent NE, Albuquerque NM 87112. All entries must include a summary sheet, and entries with over 200 QSOs must include dupe sheets. Include a large SASE for results.

SARTG WORLDWIDE RTTY CONTEST
Contest Periods:
0000 to 0800 GMT August 20
1600 to 2400 GMT August 20
0800 to 1600 GMT August 21

This is the 12th annual contest sponsored by the Scandinavian Amateur Radio Teletype Group (SARTG). Operating classes include a) single operator, b) multi-operator, single transmitter, and c) SWL. Please note that the logs from multi-operator stations must contain the names and callsigns of all operators involved. The same station may be worked once on each band for QSO and multiplier credits. Only two-way RTTY QSOs will count.

EXCHANGE:

RST and QSO number.

SCORING:

QSOs with your own country count 5 points. Other countries on the same continent count 10 points. Other continents count 15 points. In USA, Canada, and Australia, each call district will be considered as a separate country. Use the DXCC list and the above-mentioned call areas for multipliers. Note that contacts with a station which would count as a multiplier must be found in at least 5 logs or a contest log must be received from the multiplier station in order to be valid. Final score is the sum of QSO points times the sum of the multipliers. SWLs use the same rules for scoring, but based on stations and messages copied.

AWARDS:

Top stations in each class, country, W/K, VE/VO, and VK call district.

ENTRIES:

Logs must be received by October 10th and should contain band, date/time in GMT, callsign, exchanges sent and received, points, multipliers, and final score. Use a separate sheet for each band and enclose a summary sheet showing the scoring, classification, callsign, name, and address. Multi-operator stations should include the names and callsigns of all operators involved. Comments will be very much appreciated by the contest committee. Send logs to: SARTG Contest and Award Manager, C. J. Jensen OZ2CJ, PO Box 717, 8600 Silkeborg, Denmark.

SOUTHWEST MICHIGAN AMATEUR RADIO TEAM

NEWSLETTER OF THE MONTH

Reminiscent of Clark Kent dashing into a telephone booth and returning as Superman, this month's winning newsletter recently received quite a face-lift. The makeover began when the club changed its name from the Oshtemo Amateur Radio Club, a rather plebeian title, to the Southwest Michigan Amateur Radio Team—or SMART, for short. To the name change, add a club member who also happens to be a graphics artist and you get a handsome logo such as the one adorning the SMART newsletter masthead.

Newsletter editor Clint Williams KB8SY said the name change was prompted by the club's acquisition, through an anonymous donor, of an ACC repeater controller. Not many clubs are that lucky, and SMART has made the most of their good fortune.

The newsletter offers the latest information on upcoming events, board meetings, and RACES. In addition, the Letters to the Editor column is often filled with controversial subjects and provides a forum for all of the club's 160 members to speak their piece. Some of the reports in the SMART newsletter have been on the Skywarn Net, the technical committee's efforts to make the most use of the new repeater controller, the Slow-Speed CW Net, and, last but not least, on members who have recently upgraded.

Congratulations to the SMART team not only for having an active club, but also for having the foresight to provide an equally active newsletter to back it up.

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send a copy to *73*, Pine Street, Peterborough NH 03458.

CALENDAR

Aug 6-7	ARRL UHF Contest
Aug 13-15	New Jersey QSO Party
Aug 19-21	*A5 Magazine* UHF FSTV DX Contest
Aug 20-21	SARTG Worldwide RTTY Contest
Aug 20-21	New Mexico QSO Party
Aug 27-28	Occupation Contest
Sep 3	DARC Corona 10-Meter RTTY Contest
Sep 9-11	Connecticut Oyster Festival
Sep 10-11	ARRL VHF QSO Party
Sep 10-11	Cray Valley Radio Society SWL Contest
Sep 17-19	Washington State QSO Party
Oct 1-3	Oregon QSO Party
Oct 8-9	ARRL QSO Party—CW
Oct 9-10	ARRL QSO Party—Phone
Oct 15-16	ARRL Simulated Emergency Test
Oct 22-23	Pennsylvania QSO Party
Oct 22-23	MF Runde SW Activity Weekend
Oct 22-23	CLARA Ac-Oc Contest

Nov 19-20	ARRL Sweepstakes—Phone
Dec 3-4	ARRL 160-Meter Contest
Dec 10-11	ARRL 10-Meter Contest
Feb 4-5	South Carolina QSO Party
Feb 18-19	America Radio Club International DX Contest

RESULTS

1982 AMERICA RADIO CLUB INTERNATIONAL DX CONTEST

1.	Angel Romero WD4CPS	4450 points
2.	Elpidio Padilla WD4GZI	3475 points
3.	Tony Pineda WD4MXF	2700 points
4.	Juan B. Huarte KA4BBR	2600 points
5.	Guillermo Cabrera WD4FHM	2525 points
6.	Roberto Suarez KI4S	2150 points
7.	Orestes Falcon WD4HZR	2125 points
8.	Lily Suarez N4DJI	2100 points
9.	Idelfonso Martinez WD4EMB	2025 points
10.	Milton Romero WD4ELB	2000 points

OCCUPATION CONTEST
Starts: 1800 GMT August 27
Ends: 2400 GMT August 28

The Radio Association of Erie PA is sponsoring their third annual contest. The contest is open to all amateur radio operators. The rules have been changed this year so that individual occupations will be of greater importance. This change should make this year's contest less confusing and more enjoyable.

EXCHANGE:

RS(T); occupation; and state, province, or country.

FREQUENCIES:

CW—40 kHz from the bottom of the ham bands. Phone—1820, 3920, 7250, 14300, 21400, and 28600.

SCORING:

Score 3 points for each new occupation worked, one point for all similar occupations worked, and 2 points for all retirees worked. There are no multipliers.

AWARDS:

A plaque will be given to the top-scoring station. Certificates for the top stations in each state, province, and country.

ENTRIES:

Mailing deadline for logs is October 1st. They should be sent to: Chris Robson KB3A, 6950 Kreider Rd., Fairview PA 16415.

RADIOS WE HAVE KNOWN

Do you remember the first rig you ever owned? Of course you do. To a ham, that first transceiver, transmitter, or receiver is like a first love—a memory to be nurtured and cherished forever. I'll never forget my first rig. Unlike most old-timers, my initial radio was a VHF job—the venerable Heathkit* Sixer. I can still remember gently cradling the package in my arms as I rode the subway home from the old Heathkit store on New York's West 45th Street. Tossing homework and other chores aside, I constructed my first rig during a single weekend orgy of soldering and wiring. I still bear a one-inch scar on the spot where I tried to solder a diode to my left arm. Ah, memories.

The only unpleasant experience I ever had with that radio came at the moment I unveiled it to my "Elmer." He laughed. Never having heard of VHF construction techniques, I had oscillator caps and resistors dangling on two-inch leads and enough cold solder joints to make a Heath technician cry. Still, with some help, I eventually got my Sixer running and made quite a few DX contacts during the terrific sunspot summers of 1968 and 1969.

I have no idea whatever happened to that wonderful old rig. It was lost while moving during the spring of 1972. Today, I use a Kenwood TS-520 and a transverter on six. You know, I miss the roar of that old super-regenerative receiver.

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1) Commercial-made boat anchor
7) Crystal oven entrance
8) Ham antenna maker killed by CB boom
11) Interference type (abbr.)
12) Fellow ham (abbr.)
16) Dry
17) Kit brand formerly sold by Allied
19) Another kit maker
21) Book publisher or bill
24) Cornell-________
26) KP4-land city: San________
27) Operator (abbr.)
30) Ø-land state (abbr.)
31) Nationwide electronics chain (2 words)

Down

1) Last great kit seller
2) Month before Field Day
3) Former tube maker
4) Ø-land state (abbr.)
5) Canada's radio authority (abbr.)
6) Prototype surfaces
8) Telegraphic laugh
9) Northern Ireland prefix
10) Negative reply
13) Two connectors that join
14) 8-U, 59-U
15) Telegraphic thank you
18) Stand by
20) Telegraphic query
22) Rig type
23) Grid________meter
25) Take one rig and another
26) Slang for tube
28) Canada prefix
29) Current type (abbr.)

ELEMENT 2—MULTIPLE CHOICE

1) Sonar Radio, the former famous maker of VHF ham transceivers, currently manufactures:
1) HF rigs
2) CBs
3) antennas
4) computer peripherals

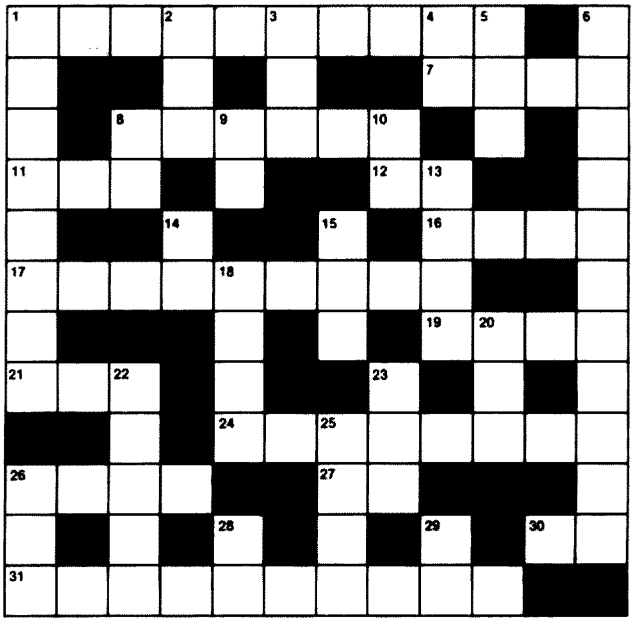

Illustration 1.

2) The first popular 2-meter transceiver was the:
1) Galaxy Hightopper
2) Clegg Odin
3) Gonset Communicator
4) Kenwood TS-520

3) An "audion" was:
1) a type of amplifier
2) a tube
3) an old-fashioned oscillator
4) a musical instrument

4) Which of the following was NOT a Hallicrafters rig:
1) SX-111
2) HT-17
3) HT-220
4) Super-Skyrider

5) E. F. Johnson's HF transmitter kit was known as the:
1) Viking
2) Signal Slicer
3) Comet
4) Q5er

ELEMENT 3—MATCHING I

Match the former ham manufacturers and distributors in Column A with their QTHs in Column B.

Column A	Column B
1) Sideband Engineers	A) Oceanside CA
2) Sonar Radio	B) Brooklyn NY
3) LTV-University	C) Burbank-Anaheim CA
4) Squires-Sanders	D) Chicago IL
5) Regency	E) Jamaica-Syosset NY
6) Galaxy	F) Millington-Watchung NY
7) Terminal Radio	G) Buchanan MI
8) Burstein-Applebee	H) Indianapolis IN
9) Lafayette Radio	I) Jersey Shore PA
10) Amperex	J) San Francisco CA
11) Greenlee Tool	K) Hicksville NY
12) Gonset	L) Harrison NJ
13) Hallicrafters	M) Council Bluffs IA
14) RME-ElectroVoice	N) Kansas City MO
15) Alltronics-Howard	O) Mars Hill NC
16) Uncle Dave's Radio Shack (Fort Orange Radio)	P) Albany NY
17) Atlas Radio	Q) Oklahoma City OK
18) Hammarlund	R) Boston MA
19) E. F. Johnson	S) Waseca MN
20) RCA Electron Tubes	T) Rockford IL
	U) New York NY

ELEMENT 4—MATCHING II

Match the current ham manufacturers and distributors in Column A with their QTHs in Column B.

Column A	Column B
1) Spectrum Communications	A) Urbana IL
2) Larsen Antennas	B) Buffalo NY
3) Macrotronics	C) Miami FL
4) GLB Electronics	D) Miamisburg OH
5) Communications Specialists	E) San Diego CA
6) Antenna Specialists	F) Turlock CA
7) Hustler	G) Cedar Rapids IA
8) HAL Communications	H) Norristown PA
9) MFJ Enterprises	I) Steadhemp NY
10) Kantronics	J) Lawrence KS
11) Amateur-Wholesale Electronics	K) Kissimmee FL
12) R. L. Drake	L) Bristol PA
13) Cushcraft	M) Lynnwood WA
14) Advanced Electronic Applications	N) Lancaster PA
15) Collins Radio	O) Vancouver WA
16) Robot Research	P) Morgan Hill CA
17) Clegg Communications	Q) Cleveland OH
18) KLM Electronics	R) Manchester NH
19) Ham Radio Center	S) St. Louis MO
20) Barker & Williamson	T) Mississippi MS
	U) Orange CA

ELEMENT 5—TRUE-FALSE

	True	False
1) The famous Drake 2-meter portable—the TR-22C—was actually made by Kenwood.	___	___
2) A famous semi-automatic keyer was known as the Blitz Bug.	___	___
3) Arthur A. Collins W9CXX was the founder of Henry Radio.	___	___
4) During its entire history, International Crystal has manufactured only one type of product—crystals.	___	___
5) The first transmitter offered by Heath was the Mohican.	___	___

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—4 1975: Ham makers turn to CB. 1983: Ham makers turn to computers. 1990: Automobile makers turn to ham radio?
2—3 The year was 1952 and the mode was AM. Could the first jammer be far behind?
3—2 Lee DeForest's revolution in electronics; the audion was the first triode.
4—3 The HT-220 is Motorola's popular VHF hand-held transceiver.
5—1 More than one Novice's first rig.

Element 3:
1—J, 2—B, 3—Q, 4—F, 5—H, 6—M, 7—U, 8—N, 9—E, 10—K, 11—T, 12—C, 13—D, 14—G, 15—R, 16—P, 17—A, 18—O, 19—S, 20—L.

Element 4:
1—H, 2—O, 3—F, 4—B, 5—U, 6—Q, 7—K, 8—A, 9—T, 10—J, 11—C, 12—D, 13—R, 14—M, 15—G, 16—E, 17—N, 18—P, 19—S, 20—L.

Element 5:
1—True It was almost identical to Kenwood's own TR-2200, except that the Kenwood model had additional channels.
1—False Vibroplex's bug was called the "Lightning Bug." The "Blitz Bug" is Cushcraft's lightning arrestor.
3—False How about Arthur Radio? Collins Radio.
4—False The company has, from time to time, made and sold receivers, oscillators and other products.
5—False The AT-1 in 1953.

SCORING

Element 1:
Twenty points for the completed puzzle, or one-half point for each question correctly answered.

Element 2:
Four points for each correct answer.

Element 3:
One point for each correct match.

Element 4:
One point for each correct match.

Element 5:
Four points for each correct answer.

Have the mists of nostalgia dimmed your memory?
1-20 points—First rig was a CB.
21-40 points—Can't remember your first rig.
41-60 points—Your first rig was your only rig.
61-80 points—Still own every rig you ever used.
81-100 points—First rig was a Collins.

NEW PRODUCTS

NEW CRYSTAL CATALOG AND CROSSOVER LIST

A new 32-page crossover list and custom crystal catalog is now available from International Crystal Mfg. Co., Inc.

A comprehensive crossover listing of the most popular types of commercial two-way equipment is featured. This listing provides the user with the ICM crystal catalog number referenced to the manufacturer's equipment number.

A complete listing of ICM custom crystals featuring charts to establish ICM catalog numbers along with available holder dimensions is included.

To obtain your copy, write to *International Crystal Mfg. Co., Inc., Dept. G, PO Box 26330, Oklahoma City OK 73126.* Reader Service number 480.

BASE 2 SYSTEMS' "MUFPLOT"

Base 2 Systems has released software which for the first time enables shortwave listeners and amateur radio operators to predict band openings at the start of each day instead of relying on one- to three-month-old estimates from periodicals. The program also computes the great-circle bearing and distance to a target area.

Dubbed "Mufplot" because it plots Maximum Usable Frequency, the program is versatile and easy to use. After being customized to the latitude and longitude of the purchaser, it computes the best frequencies for a 24-hour period to any country or US state, or to any of eight world regions. Plots of MUF to ships at sea, DXpeditions, or other special locations are obtained by entering the appropriate latitude and longitude instead of a radio prefix. Graphs can be in either the user's local time or UTC.

Computation of MUF is accomplished by inputting daily solar flux data from reports of WWV or others into the program's analog of an ionospheric emulation developed through US naval research.

Output to either video display or printer consists of a graph of MUF and text. Mufplot is available now for the Commodore VIC-20 with 16K expansion and the Commodore 64, and a Radio Shack Color Computer version will soon be available.

For more information, contact *Base 2 Systems, 2534 Nebraska St., Saginaw MI 48601; (517)-777-5613.* Reader Service number 476.

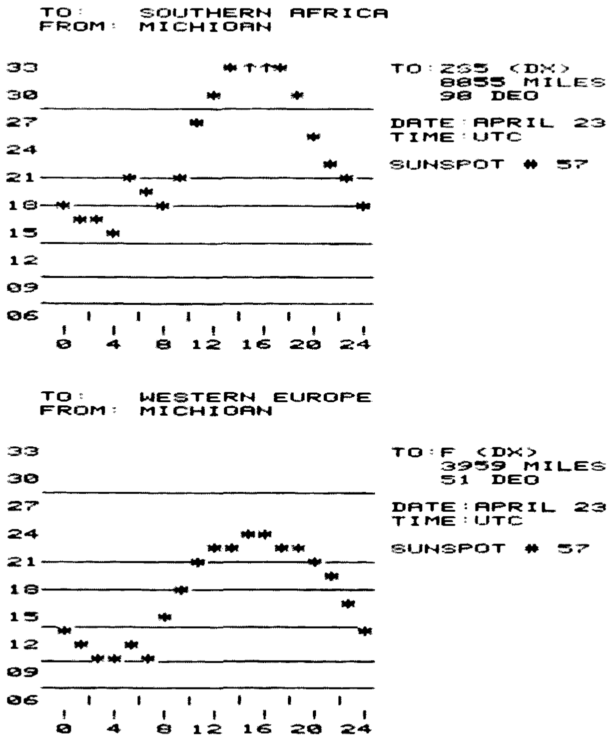
EASY-TO-SHIP SATELLITE DISH

A 16-foot satellite antenna aptly named "Silver Max" is the latest offering of Continental Satellite Systems of Clackamas, Oregon.

The Silver Max was developed and manufactured to solve the problems of those who require maximum power of a large dish but are in locations like Hawaii, Alaska, Puerto Rico, Colombia, or the Bahamas, where normal shipment of big antennas is difficult or impossible. The Silver Max can be shipped by UPS or air freight.

The 16-foot model joins Continental's 12-foot "Silver Feather," the 10-foot "Silver Star," and the 8-foot "Silver Edition."

For more information, contact *Continental Satellite Systems, PO Box 648, Oregon City OR 97045; (503)-656-2774 or (800)-331-2774.* Reader Service number 481.



Sample Mufplot printout.

AMATEUR TV RECEIVING CONVERTER

Communications Concepts has announced its new ATV-2 amateur television receiving converter. The ATV-2 has two super-sensitive rf preamplifier stages using the low-noise MRF-901 (1.7 dB NF) transistors. The ATV-2 tunes from 420-450 MHz and downconverts to channels 2, 3, or 4 on your standard TV set. The circuit uses durable microstrip design for stability and simplicity. The combination of a dual-rf stage, the microstrip design, and the hot-carrier diode double-balanced mixer reduces UHF TV intermod problems. The local oscillator is varactor-controlled for ease of tuning. An additional feature not found on other ATV downconverters is the incorporation of a post-amplifier stage (6 dB minimum gain) following the double-balanced mixer. This post-amplifier stage is used to overcome the conversion loss of the mixer. It also delivers a signal level that is acceptable to the TV set to overcome the TV set's sensitivity threshold. The addition of the post-amplifier circuitry is most noticeable on very weak signal reception.

For more information, contact *Communications Concepts, Inc., 2648 North Aragon Ave., Dayton OH 45420; (513)-296-1411.* Reader Service number 485.

MICROLOG'S SINGLE-BOARD TU

Microlog has announced the AIR-1, a single-board terminal unit and operating program that needs no external power supply or extras to put your VIC-20 computer on CW and RTTY. The AIR-1 features the Microlog CW-decoding algorithms and computer-enhanced RTTY detection. Plug-in jacks make connection to your radio simple and the on-screen tuning indicator and an audio reference tone make it easy to use. A Microlog feature allows you to select the size of your text buffer and 8 "HERE IS" messages from the available computer RAM. It automatically takes into account any memory-expansion cartridges you have added. Baudot, ASCII, and Morse speeds are fully adjustable and WRU and selcal routines are included.

The AIR-1 fits directly into the VIC expansion port and is compatible with popular expander boards.

For more information, contact *Microlog Corporation, 18713 Mooney Drive, Gaithersburg MD 20879; (301)-258-8400.* Reader Service number 479.

TEN-TEC 2M HAND-HELD

Ten-Tec has announced a new 2-meter hand-held transceiver designed in collaboration with Motorola. The model 2591 HT is a fully-synthesized rig using a keypad for frequency and function control. The transmitter puts out 2.5 W or 300 mW with a maximum current drain of less than 700 mA. The HT will step up or down in 5-, 10-, 15-, 25-, or 30-kHz steps, and there is room for 10 stored frequencies and repeater offsets. The scanning feature allows for a progammable band scan or a memory scan, with special lockout provisions for unwanted frequencies. Standard accessories for the 2591 include a rubber-ducky antenna and a wall charger.

For more information, contact *Ten-Tec, Inc., Sevierville TN 17862.*

MFJ'S VHF CONVERTER

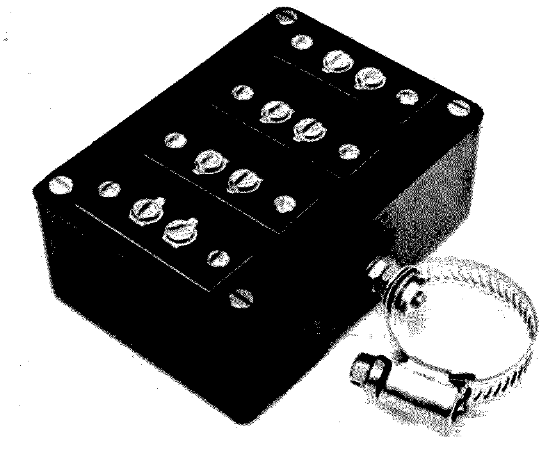
Triple the usefulness of your 2-meter handie-talkie with this new MFJ-313 police-, fire-, and weather-band converter. The compact VHF converter mounts between your handie-talkie and rubber ducky antenna and turns any synthesized rig into a public-service band receiver. The converter also will give you direct frequency readout and allow simultaneous scanning of both 2 meters and police bands. A high-pass input filter and a 1.0-GHz transistor give you very high uniform sensitivity over both the 154-158-MHz and 160-164-MHz ranges. Each band is crystal-controlled for excellent stability. An automatic bypass allows transmitting through the converter without burnout.

For more information, contact *MFJ Enterprises, 921 Louisville Rd., Starkville MS 39759; (800)-647-1800.* Reader Service number 478.

POLYPHASER PROTECTION

With X PolyPhaser's new rotor-cable lightning protector, you can obtain proper protection for your shack's rotor control box. The 8-conductor model IS-RCT is designed to have a fast response time with 50-nanosecond, three-element crowbar gas tubes. You can mount it on a ground pipe or tower leg, and the case is made with UV stabilized plastic and stainless-steel grounding hardware.

For additional information, contact



The PolyPhaser rotor-cable lightning protector.

PolyPhaser Corporation, 1500 West Wind Blvd., Kissimmee FL 32741. Reader Service number 477.

AEA'S AMT-1 AMTOR TERMINAL UNIT

Advanced Electronic Applications, Inc., has released the AMT-1 AMTOR terminal unit which offers full AMTOR error-correcting data communications plus RTTY, ASCII, and CW modes as well. The AMT-1 will operate with most HF recievers, home computers, or data terminals, and both the mode and configuration may be controlled either from the terminal keyboard or by computer program. This terminal unit offers both ARQ and FEC AMTOR modes, RTTY from 1 to 100 baud, CW transmission from 1 to 99 wpm, and ASCII communications to 110,300 baud. An RS-232 interface is used to connect the terminal unit to a computer, and the modem offers an active 4-pole receive bandpass filter feeding into an audio discriminator. The frequency shift is 170 Hz using standard tone pairs. The AMT-1 will operate from any external power supply providing 12 V dc regulated at .85 A.

For more information, contact *Advanced Electronic Applications, Inc., PO Box C-2160, Lynnwood WA 98036; (206)-775-7373.* Reader Service number 482.

AEA's AMT-1 AMTOR terminal unit

REVIEW

WHAT I THINK ABOUT DGM'S SRT-3000

Having spotted the box on page 116 of the May issue ("What Do You Think?"), I feel inspired to submit the following account of my experiences with one of the products advertised in *73*, shown on page 51 of the same issue.

My initial contact with DGM Electronics, Inc., located in Beloit WI, was when I wrote to inquire about the SRT-3000, a "high-performance RTTY communications send-receive terminal," to quote the company's advertisement. Brochures arrived in a few days, and although some were Xerox copies of typewritten originals, the information was pertinent and well-presented. (The fact that some material was Xeroxed posed no problem; rather, it told me that this was a new organization doing its best to get started on a small budget.)

My second inquiry brought a personal letter from Dennis G. Makovec WA9CIY, along with a copy of the instruction manual for the SRT-3000. I assume Dennis's initials form the company logo. The manual proved to be superbly-assembled and well-planned, including 28 pages of explicit instructions purely on the operational capabilities of the terminal.

An order was placed with DGM for an SRT-3000 and a video monitor around March 1, and UPS delivered two well-packaged cartons about two weeks later. The keyboard and monitor were connected to my two-meter transceiver with a minimum of trouble. Both a discussion and a block diagram are provided in the manual for the various connections and options. Yes, RCA phone jacks are used, but they are of high quality and a positive "feel" is obtained when plugging in the cables. The unit has been used daily, and no connection problems have been encountered.

When turning on the power, a status line appears on the monitor, displaying the mode, amount of frequency shift, transmit buffer status, speed, and a real-time clock that can be set by keying in the correct time followed by whatever one chooses, such as the date. Then, whenever the appropriate command code is issued, the unit will transmit the time and other information as was entered previously. A very handy feature for logging during QSOs, assuming one still maintains a log! Other information presented by the status line includes a tuning bar along with various receive options.

Since anyone can read the various features in the ad, I'll elaborate a bit on some of the aspects that are not mentioned specifically, but which are examples of how well-planned this device was. For instance, selcal (selective calling) is a feature which prevents the unit from displaying on its screen and/or on an associated printer unless a certain sequence of characters is received first. This sequence is most often the callsign, or at least the suffix of the station call. The ending sequence is usually NNNN, which is programmed into the SRT-3000 (although it can be reprogrammed by the user). What this means is that the screen remains blank and a printer (if used) remains quiet unless someone sends your station call. Then the screen and printer become active, displaying all incoming characters until NNNN is received. (See "The New Communications: VHF Mailboxes," by AF2M, page 48, May, for details.)

A great idea, right? If no printer is used, selcal can save messages to you rather than having them scroll off the screen, while in cases where a printer is used, appreciable amounts of paper are saved. But the DGM SRT-3000 also has W-R-U ("who are you"), which has its own activation code, that in turn triggers a response from the terminal that turns on the transmitter and sends a canned message. The idea here is that others can verify that you are, in fact, monitoring. My concern was that the selcal code (again typically the station callsign) and the W-R-U code (usually the staton's call plus ZW or something similar) would pose a problem: If someone sent the station call, the terminal would accept the incoming call if it happened to be in the selcal mode but would reject the incoming call if left in the W-R-U mode, since the W-R-U requires the additional characters. In other words, how should one leave the unit? In selcal and get all calls but not provide a response? Or in W-R-U and get only those calls that included the ZW tacked onto the end of the station callsign, but provide confirmation?

Well, the people at DGM thought of that: what it amounts to is that the terminal is both in selcal and W-R-U when in the W-R-U mode, which of course means that it will dutifully record incoming messages addressed to the station callsign only and/or record messages and respond to those which contain the extra characters. What more could you want?

As a matter of fact, a "break" feature would be nice, and the SRT-3000 has one. Imagine yourself having just loaded its thousand-character transmit buffer with a response message to the chap you're in QSO with, when all of a sudden he asks a question that deserves an immediate response. What to do? Ignore his question until you have run the contents of the buffer, or clear the buffer, answer the question, and then start all over again? No problem with this terminal: Simply hit "control-break," "transmit," and answer the question. Then hit "escape," and the buffer, safe and sound, will also be transmitted.

A word about modes: The SRT-3000 transmits and receives Morse, Baudot, and ASCII at a variety of speeds. It generates both high and low tones, including "modem" tones for those wishing to use the many bulletin boards available on telephone circuits.

Mode, speed, and tone changes are only a couple of keystrokes away, which is a joy for an old teletype* hack like me. I am accustomed to opening up a printer, unbolting the typing unit from its base, lifting it off, and exchanging a pair of gears, followed by reassembly and a thorough hand-washing to remove ink and grease each and every time a speed change was desired. Now I change speeds electronically, in the length of time it takes to type three or four characters. To go from Baudot at 60 wpm to ASCII at 110 baud, I hold "control" and type A110 and then release "control." Other speed and mode changes are equally simple: M for Morse, B for Baudot, etc.

Anyone who (a) is learning Morse code or (b) is teaching others will find the random code generator a joy. With a cassette tape recorder attached to the SRT-3000 cassette port, and a printer, the terminal generated beautiful Morse in five-character random groups, either letters only, or letters, figures, and the four required punctuation marks (period, comma, slant bar, question mark). The cassette machine gets the Morse characters, of course, and the printer types the groups in perfect columns. What a great way to produce practice material! And speeds are in 1-wpm increments, as determined by the operator, from 1 to 99 wpm. You want clear text in Morse? Type it into the transmit buffer (1000 characters maximum), turn on the cassette machine and printer, turn off the transmitter unless you want it to go over the air, and proceed. Perfect copy is the result. I taught a licensing course for several years at the local community college, and how simple it would have been to generate practice cassettes for my students had I owned an SRT-3000! Mr. Green is probably glad I didn't, because my recommendation was that students purchase the *73* code practice tapes, hi.

Something else you should know: the SRT-3000 has a printer port that can be programmed by keystrokes to any of the standard speeds in either ASCII or Baudot. The port will stay in that mode regardless of the incoming and outgoing language being used. For example, I am using a teletype model 35 which is an ASCII printer running at 110 baud. I have the printer port set for that mode, and no matter what I'm using to communicate over the air, the model 35 gets it all. You read it right: I can be using Morse, Baudot, or ASCII over the air, and the SRT-3000 translates it all to ASCII at 110 baud and sends it to the printer. So don't give that model 15 or 28 away quite yet; it's just as easy to program the printer part of them. Why am I using a model 35? Because it gives me the extra ASCII characters and

The DGM Electronics SRT-3000.

higher speed that the Baudot machines cannot accommodate. But a Baudot printer would still serve as well, except at higher speeds.

If I had to find fault with the SRT-3000, it would be this: DGM does not presently provide an annunciator to serve as the signal bell. The terminal will transmit the "bell" code just fine, but it ignores it when received. Perhaps something can be added. A gentle "peep" upon receipt of a bell code would be nice, and maybe it could even be toggled on and off. But considering all aspects, I think the SRT-3000 is superb. The price is $1144 including a video monitor. 73 and happy RTTYing.

For additional information, contact *DGM Electronics, Inc., 787 Briar Lane, Beloit WI 53511.*

QZX

A newsletter? How do you review a newsletter for *73*? It doesn't beep, light up, plug in, or charge your batteries.

But *QZX*, the newsletter for hams who own Sinclair/Timex computers, does transmit. It transmits a lot of very good information, and we thought the best way to bring it to our readers' attention would be through a close look at what it does provide.

First, let's start out with the products it serves—the ZX-80, Micro Ace, ZX-81, and TS-1000. With an average $50 price tag, these are among the best computer buys a ham can make. A low-end computer is one of the best ways to get on RTTY or packet radio, costing less than many a model 33 in the flea market. A small extra investment in time to write software and build an interface with your rig is all you need—and that's time you would spend cleaning grease off the gears of an old Teletype® machine.

Ham applications for computers differ from many others in that they do not require large amounts of memory, rapid storage-medium access, or complex mathematical calculations. What they do require is easy access to I/O ports and simplicity of real-time programming. The Sinclair, with its TTL interfacing, meets the first requirement, and the plethora of Z-80 assembly-language manuals makes learning the Timex/Sinclair computers' native language that much easier.

In addition to communications uses, you can develop the extras—like an electronic logbook, dupe sheets, or even a rotor controller. These models, with very accessible innards, seem to be designed with the hardware hacker in mind.

The Need For Support

Unless you are a super-fast designer with an endless stream of creative ideas and lots of time on your hands, you need assistance in developing uses for your computer. Computer dealers are notorious for knowing little about ham/computer interfacing, and the staff in the department stores which offer you the best prices on Sinclair/Timex computers know even less about computers in general, much less amateur radio.

This is where *QZX* comes in. As a system-specific publication, everything in the magazine pertains to your computer. As an amateur-radio publication, it offers the additional advantage of focusing on a specific area of computer use.

Published by Alex F. Burr K5XY and edited by Ambrose Barry W4GHV/5, each month's *QZX* is literally jammed with programs and circuits. For example, the April issue contained programs to compute antenna headings, manage net rosters, and calculate propagation, as well as a RTTY send/receive program. Circuits included a simple terminal unit and an interface for the Sinclair computers.

In addition to the program, a brief synopsis of each is provided. Explanations of algorithms and special instructions are included as well. And the listings are reproduced directly from the author's printout, eliminating the possibility of typing errors.

Another regular feature of *QZX* covers reviews. The publishers are up front about their policy; in one recent issue, they said "if you have objections to us doing reviews of products advertised in *QZX*, let us know. We intend to present objective comments on them. If an item advertised in *QZX* is obtained for review and found to be less than 'OK' in our opinion, we will simply decline to print that review. A rather polite way of avoiding a 'cut throat.' Those not advertised but reviewed will receive our honest opinions and will be printed."

A useful column in the newsletter is "Bits & Bytes," a compendium of useful tips similar to *73*'s "Circuits" feature. Subjects ranging from power-supply problems to photographing program listings from your video monitor are all addressed here. And if you miss a juicy topic, information on it may be recovered via the *QZX* Net, an almost nightly gathering of the Timex/Sinclair faithful, the schedule for which appears in the newsletter.

The newsletter is printed on plain paper and graphics are limited to schematics. All of this adds up to savings in production costs—savings which are passed on to subscribers. At $12 for a one-year subscription, *QZX* is much cheaper than a slick magazine, and in terms of applicable material, you probably get a lot more for your money.

From programs to reviews and advertising, *QZX* is a perfect solution to one of the great problems of owning a computer—what to do with it. As amateurs, we have the unique ability to generate new *ideas and practical uses* for *almost any* piece of electronic equipment. But newsletters such as *QZX* are necessary for us to share all of that knowledge.

For more information, contact QZX *Newsletter, 2025 O'Donnell, Las Cruces NM 88001.* Reader Service number 484.

RADIO ELECTRONICS BUYERS GUIDE

Almost every ham, whether or not a confirmed builder or modifier of radio equipment, someday will need a part or component to fill an exact requirement. Maybe it will be something as rare as a tube socket or as common as a lamp bulb or fuse holder. The home-brewer, of course, will need IC sockets, circuit boards, capacitors, resistors, displays, inductors, transformers . . . and all the rest.

Now put yourself in either pair of shoes: Where would you look for the exact part you need? Sure, you're gonna say *73*, right? Well, okay; I'll go along with you to a point . . . but suppose you have dozens of parts and items that you need. Doesn't that mean that you'll have to look through maybe dozens of ads, searching for all the things on the parts list? Right; see what I mean?

Enter the *Radio Electronics Buyers Guide*, a stupendous compendium of electronics goodies listed by type of component in alphabetical order. This beaut of a book lists it all . . . and not only one source but dozens of sources. Here, let's take a look at how it works. Suppose you need a 9900-series microprocessor—an IC. You look up IC and then the series . . . ahhh, here it is on page 46. The listing gives two sources: Active Electronics and Jameco Electronics. Active stocks a variety of 19. Now, you turn to page 88 and find Active Electronics. Their address and telephone number, as well as information about catalog cost and minimum order, is listed for your convenience. Same thing for Jameco Electronics on page 90.

Let's take a different component and try it again. What about a mechanical digital counter for a project that you have been working on? Yep, there it is on page 23, sold by BCD Radio Parts. What about a marine-band crystal for the VHF frequencies? There it is on page 24. Rolin Distributors has 'em. And so it goes, for hundreds of items.

Even if you don't build but have a friend who does, get this neat little book for him or her. It makes a wonderful present and will really be appreciated. If you're the kind of ham who has a library of needed info, get the book. Hallward Products, publisher of the *Guide*, has required that a supplier be willing to sell in small quantities to individuals by mail order. Each one has been contacted by the publisher and has agreed to the terms. The information in the *Guide* is contained in a computer and therefore can be edited and added to as the market changes.

The 1983 *Radio Electronics Buyers Guide is available from Hallward Products, 32 Sunset Court, St. Louis MO 63121.* Reader Service number 483.

ICOM's IC-490A.

ICOM'S IC-490A 430-MHZ TRANSCEIVER

Even newly-licensed hams quickly gain an appreciation for the amazing number of knobs, readouts, microprocessors, Watts, and features being crammed into smaller and smaller radios these days.

As a long-time resident of the UHF bands, I was happy to learn of ICOM's latest multi-mode radio for the 420-450-MHz band, the IC-490A, and to get an opportunity to try one out. Actually, calling the "490A" a multi-mode rig may be a bit misleading. The rig covers the 430-440-MHz portion of the band only, and in the US and Canada this does not include the portion used for FM according to the current band plan. However, if you're interested in OSCAR satellite work in the 435-MHz range or weak-signal work at 432 MHz, you'll find this rig packed with useful features.

Designed primarily for mobile use, the radio was also found to be quite acceptable for home use as well when powered from an optional 12-V-dc supply. A battery back-up option is available to maintain memory channels when the rig is removed from its power source.

When I first sat down to operate the radio, my initial impression was that there weren't nearly enough controls to operate all the features which the radio offered according to the manual. A well-thought-out control system, however, places non-routine adjustments such as scanning-speed timing, stop timing and full or programmed segment scanning internally. These adjustments are often a matter of personal preference; once these decisions are made, further adjustment is usually not necessary. In addition, many front-panel controls have multiple uses.

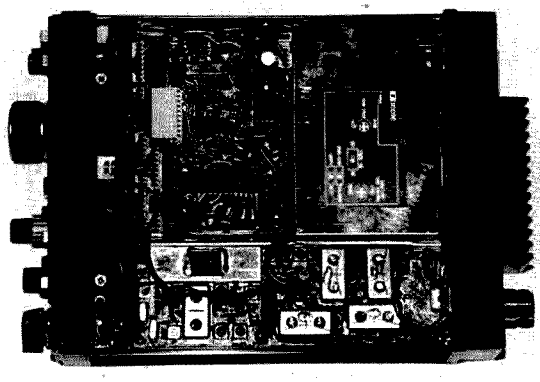
Frequency Control Features

The IC-490A's frequency control is typical of many ICOM radios. A detent-type main tuning control is used for either of two vfo's. Designated "A" and "B", each vfo is selected by a push-button switch. Vfo "A" can be used to dial up frequencies for subsequent storing in one of four memory positions. Those interested in both weak-signal work and OSCAR work as described earlier will find it useful to leave one vfo set for each range.

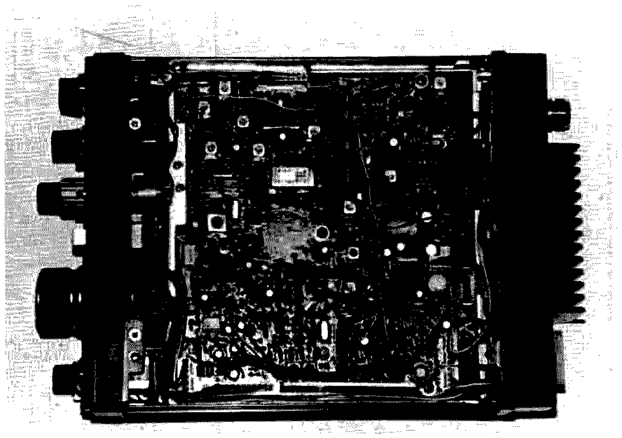
QSYing anywhere within the 10 MHz provided was actually faster than with many 144-MHz rigs I've operated. There is a "1 MHz up" button which increases the currently-selected frequency in 1-MHz steps up to 439 and then restarts at 430. In addition, four tuning spreads are provided (although it's not obvious without studying the manual). In the SSB or CW modes, each tuning step is 100 Hz. There are two FM mode positions called FM1 and FM2. Position FM1 provides tuning steps of 25 kHz, while FM2 steps the frequency 5 kHz per tuning-knob click. These are the normal tuning speeds for each mode. In addition, a "1 kHz" button overrides the tuning speed of any mode in favor of a 1-kHz-per-click rate. This scheme is a little tricky to get used to and, even after a couple of months, I still have to think about it a bit more than I'd like. It does get you around the band quickly with a minimum of extra controls, though the mode switch also permits changing the repeater offset frequency to virtually any frequency desired. Upon powering up, the radio normally comes on with a 5-MHz offset. Again, this radio does not cover the US or Canadian repeater band.

Scanning

Two types of scanning are provided: scanning of memory channels or scan-



Top view of the IC-490A.



Bottom view of the IC-490A.

ning of band segments up to the entire band. Band segments are determined by the frequencies stored in memories 1 and 2. Memory 1 would be the lowest frequency of the segment and memory 2 would be the highest.

The IC-490A also includes a priority channel feature to let you keep track of a favorite frequency or calling frequency while operating on another frequency. The priority frequency can be any memory channel. The microprocessor selects the priority channel for an automatic quick look every 5 seconds. It does not lock onto this channel even if in use and it will not switch the priority channel if you're in the transmit mode. In addition to all the vfo's, memories, and priority channels, there is a "calling channel" feature. Pushing a single button selects a programmed channel and overrides whatever memory or vfo had been in use. This channel is not scanned and, frankly, I haven't found a good use for it. But it's there for those who do.

Other features include a noise blanker which is quite effective in eliminating ignition and other pulse noises, and an agc (automatic gain control) to reduce fading (especially mobile "picket fencing," which is particularly rapid at these frequencies). An RIT (receiver incremental tuning) feature shifts the received frequency ± 800 Hz to follow drifting signals or change the other station's CW note to one which is more pleasing.

I was glad to see that ICOM used an "N"-type connector (UG-21/U) for the rf output. This type of connector is designed for use on UHF to keep losses at a minimum, but all too often manufacturers forget these details.

Frequency is displayed on a nice readout which is sufficient for precision down to 100 Hz (on FM, 4 digits provided precision to 1 kHz). For example, a frequency of 432.1985 is displayed as 2.198.5. Numerals are 3/8" high and are much brighter than the traditional red variety.

Light-emitting diodes are also used for a "light-bar"-type display of received signal strength and relative transmitter output. I must admit that I was a little prejudiced against such devices. "How can a readout of 7 or 8 diodes approach the precision of a meter?" Well, it doesn't, but with a little practice, a flickering diode can be interpreted pretty closely. And for conveying information at a glance, light bars to me are more useful. I became convinced of this when an intermittent ground on my mobile antenna would increase the vswr and decrease my power output. Since the problem was intermittent, I might have blamed my varying signal strength on normal propagation, not noticing the slight movement of the meter needle. However, the blinking diode on the light bar was immediately obvious and the antenna problem was quickly located and corrected.

Circuit Description

The IC-490A uses a 39.38-MHz phase-locked-loop local oscillator for both transmit and receive. A rotary encoder driven by the main tuning knob controls a microprocessor which in turn determines the frequency of a voltage-controlled oscillator (vco). In the SSB/CW modes, the receiver is dual conversion with i-f's of 39.38 MHz and 10.75 MHz. In FM, an additional i-f of 455-kHz is used for triple conversion.

When transmitting in SSB, a carrier frequency of 10.7485 MHz for USB and 10.7515 MHz for LSB is fed to a balanced modulator. After filtering of the appropriate sideband, an SSB signal of 10.75 MHz is obtained. For CW operation, the USB carrier is shifted +800 Hz. This was found to be convenient when frequent mode changes take place between USB and CW. If you are in the CW mode and tune in an SSB station, you don't have to return when you change mode.

In FM, a separate crystal oscillator produces a 10.75-MHz signal which is modulated separately. A 28.68-MHz second local oscillator and an approximately 390-MHz first oscillator controlled by the microprocessor and vco puts you in the band. Rf power output is 10 Watts.

The manual is 45 pages in length, of which 13 pages are devoted to the circuit-description portion. For those wishing to get into the "nitty-gritty" of how the 490A does its thing, this section is certainly clear and concise (with liberal use of block diagrams, charts, and schematics). The largest section is the 14-page "operation" part which is, in my view, required reading. Only a page or two is needed to get you on the air, but to fully explore the intricacies and capabilities of this radio, time should be spent with this section and several pages devoted to control functions.

The manual was very complete, with extra information on satellite operations, drawings illustrating mobile installation, and two foldout inserts. One is a schematic diagram large enough such that every component can be seen clearly. The second insert is a large board layout which shows each circuit board full size, with several colors indicating all circuit paths on double-sided boards.

Likes and Dislikes

Only a few things bothered me about the radio. First, there is no rf gain control, although I must admit that it was several weeks after I began using the radio before I missed it. I have yet to find any multimode rig which includes provisions for a narrow CW filter even as an option. The agc recovery time was a little slow even in the fast position. The radio's front end tends to get "crunched" a bit by strong locals and the agc can pump somewhat and mask weak signals.

On the positive side, this is really a "fun" radio to use, especially after I gained some proficiency in making my way about the band using the memory channels and other features to their fullest. I used the radio during the Spring Sprint Contest and I attribute several contacts and sections to the radio's ability to quickly switch between a number of frequencies and keep tabs on the band.

Even at home, I found myself increasingly using the 490A instead of the "big rig." CW operation was very pleasant, with a nice sounding CW sidetone. Excellent on-the-air reports were received on both CW and SSB. Receiver sensitivity was very good.

In summary, I found the IC-490A an excellent radio as a primary station or as a secondary station for those who have already gone the "transverter route." So be careful—the IC-490A may become your primary station.

For further information, contact *ICOM America, Inc., 2112-116th Ave. NE, Bellevue WA 98004; (206)-454-8155.* The retail price is approximately $650.00.

LETTERS

FUN FRACAS

I'm writing in reference to the Fun! poll results that were published in your May, 1983, issue. My complaint is about John Edwards' comments on questions 31 and 32. On question 32 he agrees with the majority opinion by saying "Free speech lives!", thus saying that politically-oriented nets are OK. But on question 31, he wants to deny the right of free speech to those who like to talk about ideas of a religious nature. He does this by saying "amen" to the majority who said no to religiously-oriented nets.

This is a very hypocritical viewpoint. If Mr. Edwards or anyone else doesn't like to listen to religious viewpoints or discussions about the Bible, they can employ their own form of censorship, tune to another frequency, or turn off their radio.

Well, Wayne, that's my viewpoint on the subject. Except for this one minor point, you have a great magazine. Please keep up the good work.

TERRIFIC TEN-TEC

Ten-Tec treats me very well. They make quality gear. Dick Frey and company are quick to keep it running. They care about their customers and are always more than fair. I have had two, and my next one will be a Ten-Tec also.

Bob Solon WD8LKI
Toledo OH

SCAPEGOATS

It appears that every time someone loses touch with reality, they blame the steel and auto workers for the economic plight of their industries. The workers' wages are always compared to those of the Japanese, and the conclusion is made that the Americans are getting paid too much.

How about comparing the US executives to their Japanese counterparts? They get 4 or 5 times as much, not just 10 or 15 percent. Another thing is taxes; 35 to 45 percent of our wages go to pay some kind of tax. If these taxes were eliminated, we could live on the same pay and benefits as the Japanese. By the way, I wonder what

nagazine editors are paid in Japan. Maybe by their standards, you're overpaid, too!

Western Springs IL

AMERICAN TRAGEDY

I would like to know if you could give me some information. I bought a Swan 700 CX and 117 XC power supply about seven years ago. I really liked it and always had good reports with it. Several months ago, I went out and forgot to ground my antenna and it was hit by lightning.

Well, I could not get any of the elec-ronics service places to repair it. They all told me that they don't service Swan any more. Finally, I got a couple of hams to ook at it and they told me it was damaged too badly to fix. I sent the power supply all the way out to New Mexico and had it re-paired. Now I am stuck with a power supply and no transceiver.

I was laid off at Piper Aircraft in Vero Beach FL just about a year ago. So I can-not afford a new set or a second-hand rig or cash. all of the amateur electronics stores only have Master Charge, Visa, or American Express cards.

I would like to know if you know of any amateur stores that do their own financ-ng anymore. At least maybe my wife could get financing so that I could buy omething.

I have had my license since 1964, and I ure miss being on the air.

If you read this and have the time for any information, I would like to say thank ou very much.

BATTLE SCARS

I was listening on 20 recently to a cou-le of hams discussing their radio clubs. One was putting his talents on display with an outstanding choice of words poken with excellent diction. He was de-cribing not only the interesting meetings ut also the public-service involvement. He told of their emergency communica-ions equipment and training, the gigantic Field Day, and their participation in arades and other public-service events. When I thought of the efforts of our local lub, they looked pale in comparison, and urs is a "working" club.

Then the excellent speaker turned it ver to the other ham—to his opponent, I hould say. I don't know how sensitive the irst guy's ego was, but the second ham was out to smash it. Now, the second ham was no slouch at expressing himself ither, but the extremely bassy voice and he "We have all that plus. . . ," etc., ounded to me like the old put-down. Both ad beautiful signals. Too bad it had to be ension, instead of relaxation and fun.

When I was growing up, I was known to ave quite a temper. I'd get so mad I ouldn't see straight. My big brother liked o tease me because he said I looked cute hen angry, and when I was angry I could ever land a punch on him, only an occa-ional shin kick. Instead of letting off team, afterwards I always felt guilty and shamed. There was just no winning. It ook a lot of living and several changes of nvironment before I learned that you can atch more flies with honey than with negar.

Battles on the air do happen. They're un to monitor. Did you ever participate in one? One time I was working a phone patch from overseas. We did the usual fre-quency check, asking "Is this frequency busy?" No answer, so we began the patch. "Hey, the frequency up 1 kc is busy, can't you guys move someplace else?" So move we did. The same thing happened once more. Then we found a frequency that sounded pretty good so we again started the patch. This time it was much worse. We had landed on someone's pri-vate frequency. The screaming went on during and after the patch and pretty well ruined our efforts, but his unkindest cut was, "How did you manage to get a li-cense?" Somehow, I managed not to an-swer that one.

Once, after tuning the bands for a half hour looking for a CQ, and another half hour of calling CQ without result, I decid-ed to call in on this good old boy net. One member asked another "Did you hear that weak signal in there?"

"Yeah, Barney, let's let him in. Go ahead breaker."

"Hi, Fellas, thanks for letting me in. This is W9HD, W9 Hot Dog. The name is Paul. You're all coming in good here in Bloom-field, Indiana, today."

"Stan, do you know W9 Hot Dog?"

"Nope, I sure don't. Edna says she wants me to put a new bedroom on the back side of the house. . ." Well, they did let me in, but that was as far as it went.

Just a few days ago, I was again working an overseas phone patch. We landed just a kc away from the "Brown Sugar Net," and I was asked by Pete K6EDV to move. I promptly asked him to please wait, adding that this was to be a short call. Believe it or not, Pete got his net to stand by for a few minutes while ND4JPK and I handled a beautiful interference-free patch. After-wards, Pete said, "Being nice to people, isn't that what ham radio is all about?"

Paul L. Schmidt W9HD
Bloomfield IN

IMPRISONED

As you know, more and more hams are finding themselves "confined" to apart-ments, townhouses, and condos. As such, we are severely limited to the amount of wire we can string up.

I know there must be a lot of innovative designs being used for indoor/invisible antennas. But most articles (of what few there are) represent only a few various designs.

How about a general request by you to the ham community to submit designs for said antennas? It would be most ap-preciated.

I love your magazine; its worth to the ham world is heartily appreciated.

A. Reid Maertz KD5SI
Houston Tx

CALL FOR PAPERS

Papers are invited for the 1983 VHF Conference sponsored by the Electrical Engineering Department of Western Mich-igan University in Kalamazoo. The prin-cipal emphasis will be placed on engi-neering developments applied to radio communication, design, and construction on the frequencies of 30 to 1200 MHz.

One of the basic purposes of this con-ference is to provide a maximum oppor-tunity to present findings by those ex-perimenting, designing, constructing, testing, and inquiring into problems and methods applicable to VHF radio. Practic-ing engineers who are radio amateurs find this conference made for them.

This is an opportunity for beginning or mature researchers to report their find-ings to their peers. We expecially en-courage the inexperienced inquirers to obtain some experience by presenting a paper at our VHF Conference.

Authors wishing to present papers should send a synopsis or abstract (typ-ically one or two pages with diagrams) describing the paper to Dr. Cassius Hes-salberth W8FLH, Chairman, Department of Electrical Engineering, Western Michi-gan University, Kalamazoo MI 49006. For-eign authors are requested to have a US contact.

The deadline for submission of synopses is August 15, 1983. Speakers will be notified of acceptance by August 20, 1983. A reproducible copy for the printed proceedings should be mailed to the chairman one month prior to the day of the conference.

C. A. Hessalberth W8FLH
Kalamazoo MI

WEEKDAY WARRIOR

OK, Wayne, I've unloaded on New-ington and now you're next. You're just as bad as the ARRL when it cmes to major contests. Why do all of you think that everyone works Monday through Friday and is off on the weekend? What about the shift worker, whose weekends off are few and far between? What about the ones who work six days and are off only one? Or the preacher who may be avail-able on Saturday but not on Sunday? Some of us like to contest, too, Wayne, and you're not being fair to all of your sub-scribers. Your format could remain the same—just add a category for those of us who are available for only limited opera-tion (say a 6-, 8-, or 10-hour limit). That way, we can shoot for some top honors also, in our own category. Why should we participate and submit an entry when we know ahead of time we can't be compet-itive with those who were available all weekend. I managed to work six hours of the ARRL 10-meter contest even though I was working that weekend. In six hours, I had 203 contacts (not great) with 98 multi-pliers (damn good). However, I did not sub-mit an entry because there was no way that score could compete with the full weekend operator. It probably would have been a decent score in a limited-operation category.

Why should we play, Wayne, if we can't play to win? Give us weekend workers a category in the big contests also. I would even consider being a contest committee volunteer if I thought you were being fair to everyone.

Butch Lutz N5ACU
Silsbee TX

RIGHT ON, FCC

I am glad to see that the FCC has decid-ed to make the no-code license a reality. It's something that has been needed for a while. Maybe now we will see some real growth in amateur radio.

There have always been two main rea-sons given for not having a code-free li-cense. One is that the code requirement keeps the loonies off the amateur band. This just isn't so. Here in the Houston area, just listen to a few of the 2-meter repeaters. There is foul language, argu-ments, and jamming. You can hear the same type of thing on 40-, 75-, and 80-meter phone, nationwide. The second reason is that "I had to learn the code, so do they." This is really a silly reason to have a code requirement. This reason is for the self-centered person who only thinks of what he had to do to get a license.

I believe that having the Technician license as the entry to amateur radio is also good. If a person should get inter-ested in learning the code, he can and thus upgrade himself. But if he is happy with phone only and using the VHF and UHF bands, then he can stay where he is. I believe this will work well for everyone and hope that the FCC will not be swayed from carrying out this program.

Michael Friedel
Deer Park TX

SPIKE WARNING

Something happened to me last sum-mer that cost me a lot of time and effort. Perhaps some others may benefit from my experience.

I was at my well-lit workbench working on a converter circuit for the VHF region: a xtal oscillator and a frequency-dou-ble/tripler chain to get up that high. I was using my frequency counter to keep track of what each stage was doing, but I kept getting wild readings on the counter. I suspected self-oscillation and did all the standard cures: etched new boards using shorter runs, more attention to shielding, decoupling, etc. Still, erratic readings on the counter. Sometimes I would despair and put the thing aside for a while.

Then one day I had occasion to turn off my workbench light while the oscillator and counter were going, and the counter settled down to a nice, steady count, right where it should have. The culprit causing me to spend so many hours on such a sim-ple circuit was the noisy fluorescent fixture above my workbench. It was radiating a bunch of "spikes" into the counter, which was faithfully counting them along with my oscillator frequencies!

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

DARC DX AWARDS

Representing the Deutscher Amateur Radio Club (DARC), Eberhard Warnecke DJ8OT informed us about the three major awards made available to DXers by this well-known German group.

All DARC awards are based on the European Countries List. To qualify, all contacts must be made from the same country. QSL cards must be submitted with each application. All cards must be in their original form and an appropriate postage fee must be included to ensure the safe return of your cards.

The service charge is 2 US dollars per award, 1 US dollar per endorsement. $2.00 US is sufficient for the postage and handling of your QSLs.

European Countries List: C31, CT1, CT2, DL, DM, EA, EA6, EI, F, FC, G, GC (Guernsey), GC (Jersey), GD, GI, GM, GM (Shetland), GW, HA, HB9, HBØ, HV, I, IS, IT, JW (Bear), JW, JX, LA, LX, LZ, M1, OE, OH, OHØ, OJØ, OK, ON, OY, OZ, PA, SM, SP, SV, SV (Crete), SV (Rhodes), SV (Athos), TA, TF, UA1346, UA Franz Josef Land, UA2, UB5, UC2, UN, UO5, UP2, UQ2, UR2, YO, YU, ZA, ZB2, 3A, 4U1, 9H1.

Europa Diploma

To qualify for the Europa Award, applicants must provide evidence of having contacted European countries and obtaining at least 100 QSO points by utilizing the following points system: Confirmed contacts made during the current and two preceding years count 1 point. Older contacts are devaluated by a quarter point per year (i.e., .75, .50, .25). The sum of all confirmed European countries on different bands in a calendar year is multiplied by the respective multiplier points earned from making individual contacts. Contacts over 5 years prior do not qualify. See the example in Table 1.

	1977	1976	1975	1974	1973	1972	1971
Confirmed QSOs	32	48	52	44	38	36	71
Multiplier	1.0	1.0	1.0	.75	.50	.25	.00
Annual Score	32	48	52	33	19	9	0
Total Score	32	48	52	33	19	9	0 = 193

(Date of the sample application was December 31, 1977.)

Table 1.

Worked All Europe Award

WAE certificates are awarded to amateurs in three operator classes: Class WAE III—40 different countries in Europe and 100 minimum points; Class WAE II—50 different countries in Europe and 150 points earned: Class WAE I—55 different European countries and 175 points earned.

To score points, each European country counts one point on each of the six (1.8 through 28 MHz) bands. Only four bands per country, however, may be utilized for point scores. If the same station is worked on all five of the six bands, five points per country is earned. Two additional points are earned for making contacts on one of the VHF-UHF bands. Stations outside Europe may claim 2 points per European contact on 1.8 and 3.5 MHz.

The WAE series of awards is made available for either All Telegraphy or All Telephony.

EU-DX-D

This award has been claimed annually since 1964. It is issued for mixed operation, all CW, and all phone. For the mixed class, at least 30% of the contacts must be made in a different mode.

The basic idea of the award is for applicants to work all the required contacts within a single calendar year. A minimum of 50 points must be earned each year. 20 points must be made with European countries, while the other 30 points may be non-European.

All amateur bands may be used; however, a country may be contacted only once in the effort to achieve the requirements of this award.

The countries qualifying the applicant for this award appear in the European Countries List shown above. Stickers are available for each additional block of 4 European plus 6 non-European countries within the same year, ending December 31st.

The EU-DX-D may be claimed anew every year. Each year's score may be added to achieve EU-DX-D 500 and EU-DX-D 1000. A seal of merit depicts the 500 award; a special awards trophy is awarded to anyone who accumulates 1000 points.

All applications, QSLs, and awards fees should be sent to: Eberhard Warnecke DJ8OT Postfach 101244, 5620 Velbert 1, Federal Republic of Germany.

Representing the Diploma Interests Group of Germany (DIG), DJ8OT also provided me with very detailed information about the awards program being sponsored by this very unique group of radio amateurs.

Worked DX Stations Award

The WDXS Award issued by DIG is available to amateurs with no band or mode restrictions. To qualify, all contacts must be made after January 1, 1964.

This award is issued in 4 classes of operating achievement:

Class 4: DX stations must work 200 European stations, 10 of which must be on 40 and/or 80 meters. European stations must work 200 other European stations, 20 of which must be on 40 and/or 80 meters.

Class 3: DX stations must work 500 European stations, 25 of which must be on 40 and/or 80 meters. European stations must work 500 other Europeans, 50 of which must be on 40 and/or 80 meters.

Class 2: DX stations must work 1,000 European stations, 50 of which must be on the 40 and/or 80 meter band. European stations must work 1,000 other Europeans, 50 of which must be on the 40 and/or 80 meter band.

Class 1: DX stations must work 2,000 European stations, 100 of which must be on the 40 and/or 80 meter band. The requirement is the same for Europeans.

No QSL cards are required. General certification rules apply. Should all your contacts be on CW, DIG will provide a special "CW Award" sticker for this accomplishment. Fee for the WDXS Award is US $5.00 or 10 IRCs.

European Prefixes Award

The EU-PX-A is issued by DIG for contacts of 100 different European prefixes on or after January 1, 1969. There are no band or mode restrictions. Endorsement stickers are awarded for 150, 200, 250, and 300 prefixes claimed.

Should all your contacts be on CW, the sponsor has made a special "CW Award" sticker available to recognize this achievement.

GCR apply and award fee is US $5.00 or 10 IRCs.

The One Million Award

The 1,000,000 Award is issued by DIG to those amateurs who can accumulate one million points by adding together the postal codes of each German station contacted. The same postal code may be claimed only once.

In making application for this award, your list of contacts would look something like that shown in Table 2.

As you will note, the list of contacts is made in order of the postal code numbers in the right-hand column. Some postal codes may appear on your QSL or in the *Callbook* as one-, two-, or three-digit numbers. In these instances, add zeros to make four-digit codes (i.e., a postal code may appear as 41; add zeros to make it 4100).

GCR apply and the award fee is the same as with other DIG awards—$5.00 or 10 IRCs.

Worked DIG Members Award

The W-DIG-M Award is issued to those amateurs who submit proof of working DIG members on any band or mode with no restrictions as to date.

Three classes of this award are issued:

Class 3: DX stations work 15 DIG members; European stations work 50 DIG members.

Class 2: DX stations work 30 DIG members; European stations work 75 DIG members.

Class 1: DX stations work 50 DIG members; European stations work 100 DIG members.

A "CW Only" sticker is available for making all contacts on CW. GCR apply and the award fee is $5.00 US or 10 IRCs.

International Airport Award

The IAPA will be issued for contacts with amateur radio stations in 50 different cities which have international airports. All 6 continents must be worked and the applicant may claim only one contact from his or her own country. All contacts must be made after January 1, 1973, and there are no band or mode restrictions.

Fee for this diploma is US $5.00 or 1C IRCs.

Call	Date	Band	QTH	Postal Code
DL7IG	18/8/69	80	Berlin	1000
DL7TZ	12/11/68	20	Hamburg	2000
DL9KP	11/10/69	40	Duisburg	4100
DJ8OT	27/11/69	80	Velbert	5620
DL2JB	13/1/68	40	Laudenbach	6941
DL9XN	15/6/67	15	Boblingen	7030
			Total at least	1,000,000

Table 2.

CORRECTIONS

Several countries were inadvertently omitted from *73*'s Work the World DX listing on page 120 of the June issue. Contacts with the following countries are also valid QSOs for WTW:

S8	Transkei	3B9	Rodriguez Island
S9	Sao Tome and Principe	3C	Equatorial Guinea
ST	Sudan	3D6	Swaziland
STØ	South Sudan	3V	Tunisia
SU	Egypt	3X	Republic of Guinea
TJ	Cameroon	3Y	Bouvet Island
TL	Central African Empire	5A	Libya
TN	Congo	5H	Tanzania
TR	Gabon	5N	Nigeria
TT	Chad	5R	Malagasy Republic
TU	Ivory Coast	5T	Mauritania
TY	Banin	5U	Niger
TZ	Mali	5V	Togo
VKØ	Heard Island	5X	Uganda
VQ9	Aldabra Island	5Z	Kenya
VQ9	Chagos (Diego Garcia)	6O	Somalia
VQ9	Descroches	6W	Senegal
VQ9	Farquhar	7P	Lesotho
XT	Upper Volta	7Q	Malawi
ZD7	St. Helena	7X	Algeria
ZD8	Ascension Island	8Q, VS9	Maldive Islands
ZD9	Gough Island and Tristan da Cunha	9G	Ghana
		9J	Zambia
ZE	Rhodesia	9L	Sierra Leone
ZS1, 2, 4, 6	South Africa	9Q	Republic of Zaire
ZS2	Prince Edward Island	9U	Burundi
ZS2	Marion Island	9X	Rwanda
ZS3	Southwest Africa (Namibia)		
3B6, 7	Agalega and St. Brandon		
3B8	Mauritius		

Avery L. Jenkins WB8JLG
73 Staff

Two Modes Award

This award requires the applicant to work 50 different countries on CW, including Germany and all six continents, and again the same 50 countries on phone. All contacts must be made on or after January 1, 1962, to qualify.

GCR apply and award fee is US $5.00 or 10 IRCs.

Worked German Large Cities

The WGLC Award is available in three classes. There are no restrictions as to modes. There are no band endorsements. All contacts must be made by using more than one band. Each city may be claimed only once regardless of band. All contacts must be made on or after January 1, 1962.

Class 3: DX stations work 10; Europeans must work 20 cities.

Class 2: DX stations work 20; Europeans must work 40 cities.

Class 1: DX stations work 30; Europeans must work 60 cities.

Should all your contacts be made on CW, DIG has prepared a special "CW Only" sticker made available upon your initial application.

German Large Cities are: Aachen, Augsburg, Berlin, Bielefeld, Bochum, Bonn, Bottrop, Braunschweig, Bremen, Bremerhaven, Darmstadt, Dortmund, Dusseldorf, Duisburg, Erlangen, Essen, Frankfurt/Main, Freiburg, Furth, Gelsenkirchen, Gottingen, Hagen, Hamburg, Hannover, Heidelberg, Heilbronn, Herne, Kaiserslautern, Karlsruhe, Kassel, Kiel, Koblenz, Koln, Krefeld, Leverkusen, Lubeck, Ludwigshafen, Mainz, Mannheim, Monchengladbach, Mulheim/Ruhr, Munchen, Munster, Neuss, Nurnberg, Oberhausen, Offenbach/Main, Oldenburg, Osnabruck, Recklinghausen, Regensburg, Remscheid, Rheydt, Saarbrucken, Salzgitter, Solingen, Stuttgart, Trier, Ulm, Wanne-Eickel, Wiesbaden, Wilhelmshaven, Witten, Wolfsburg, Wurzburg, Wuppertal.

GCR apply and award fee is the usual US $5.00 or 10 IRCs.

As you can see, both DARC and DIG have very extensive award programs made available for you and me. Should you wish to inquire or for that matter submit application for one or more of the awards shown in this column thus far, may I suggest that you write our good friend DJ8OT directly: Eberhard Warnecke DJ8OT, Postfach 101244, 5620 Velbert 1, Federal Republic of Germany.

There remain two additional awards being sponsored by DIG; however, I wish to caution you not to apply for them through DJ8OT. The following awards have separate award custodians.

Action 40 Award

This diploma can be applied for only by licensed amateurs having proven contacts with at least 100 different amateur stations within one calendar month after November 1, 1977, on the 40-meter amateur band only.

All modes are accepted. Contest QSOs and crossband QSOs do not count. Split-frequency QSOs do count, however.

Your application must show the callsign worked, the name and QTH of the operator, mode, and date and time GMT. GCR apply and award fee is US $5.00 or 10 IRCs. Mail your application and fee to: Klaus Kleine DJ1ZP, Fasanenweg 22, D-4714 Selm-Bork, Federal Republic of Germany.

DIG Diploma 77

This diploma requires the applicant to work at least 77 DIG members from at least 7 different countries, but only 7 × 7 (49) DIG members out of one's own country, after January 1, 1977. The award is made for phone only, and mixed modes or bands are accepted. Fee is US $5.00 or 10 IRCs. For further explanation of this award or for submitting application, write to: Henry Bielinski DC6JG, Werftstr. 245, D-2300 Kiel 14, Federal Republic of Germany.

HUNTINGTON COUNTY 4-H FAIR

The Huntington County Amateur Radio Society will operate a special-event station at the Huntington County 4-H Fair on August 1st through August 3rd. The station will be operating from 2100 GMT to 0300 GMT each day using the call KC9GS. The operating frequencies will be 3900-3930, 7230-7260, 14280-14310, 21350-21380, and 28600-28630. QSL information will be given when contacts are made.

OYSTER CREEK NUCLEAR GENERATING STATION

The Jersey Shore Amateur Radio Society will operate KF2T at the Oyster Creek (NJ) Nuclear Generating Station between 1800Z, Saturday, August 6, and 1800Z, Sunday, August 7. Phone operations will be near 3930, 7230, 14260, 21260, and 28560 kHz. CW/Novice will be 30 kHz from lower band edges; VHF on 146.58. RTTY may be used on 3640, 7085, and 14085. QSLs to JSARS, 619 17th Avenue, South Belmar NJ 07719. Enclose an SASE for a commemorative QSL.

LONGEST PORCH IN THE WORLD

The Tri-County Wireless Group will operate N8COY on Aug 13, 1500-2300Z, from the famous Grand Hotel's "Longest Porch in the World," in Mackinac Island, Michigan. SSB frequencies: 7.280, 14.280, 21.380, 28.580, and FM 147.480. QSL and regular SASE to N8COY for a special QSL. DXers via Bureau.

MOUNTAIN STATE AWARD

The Logan County ARC will hold its third annual "Mountain State Award" expedition from 1600 UTC, August 20, until 0400 UTC, August 21, 1983. The callsign will be KC8NR. Operations will take place on a West Virginia mountaintop in Logan County, which is located in the heart of southern West Virginia's billion-dollar coal fields.

Phone operating frequencies will be approximately 25 kHz from the low end of the General phone bands as propagation allows. Novice band frequencies of 3725 and 7125 should be checked each hour.

A handsome 8" × 10" certificate will be awarded to all contacts submitting a QSL and a legal-size SASE to Basil Napier WD8KWC, RFD 1 Box 198, Chapmanville WV 25508.

CAMP GOOD DAYS AND SPECIAL TIMES

Ed Holdsworth N2EH, president of the Rochester (NY) Amateur Radio Association (RARA), has announced that the club will operate an amateur radio station on the site of Camp Good Days and Special Times, located at Camp Onanda on Canandaigua Lake, New York. The dates of operation will be Saturday, August 27, and Sunday, August 28, between approximately 11 am and 5 pm. The frequencies and bands are as follows: 80 meters, phone, between 3.900 MHz and 3.925 MHz, and CW, between 3.525 MHz and 3.550 MHz; 40 meters, phone, between 7.230 and 7.250, and CW, between 7.025 and 7.050; 15 meters, phone, between 21.350 and 21.375, and CW, between 21.025 and 21.075. In addition, 2 meters FM will be operated locally.

Camp Good Days and Special Times is a special camp for children who have cancer. It was established in 1980 by Gary Mervis of Rochester, the father of Teddi Mervis, a 9-year-old girl who had incurable brain cancer. Teddi passed away last year but Gary has kept the camp going and it has grown each year.

RARA members will operate the radio station, using their club callsign, K2JD. For a special certificate, confirmation of contact and an SASE should be sent to RARA, PO Box 1388, Rochester NY 14603. Camp Good Days and Special Times is a registered not-for-profit organization in New York State.

CLEMMONS UNITED METHODIST CHURCH

Throughout the month of September, WB4TAL will operate as a special-event station from within the Clemmons United Methodist Church, in Clemmons, North Carolina. The occasion is the celebration of the 200th anniversary of the church. Operation will be in the general portion of the HF phone bands and on 2 meters FM. CW will be available upon request. For a commemorative QSL card send an SASE to WB4TAL, PO Box 366, Clemmons NC 27012.

ELMER AWARD

Named in honor of all the "Elmers" who, since Marconi, have given of their time and talents to help others become amateur radio operators, the Northern New Jersey Chapter of OCWA has established its Elmer Award. The award will recognize as "Elmer-of-the-Year" the radio amateur in northern New Jersey who has done the most to pass on the knowledge that he or she has gained over the years to the next generation of amateur radio operators. The award will consist of two appropriately engraved plaques. The first will carry the name of each year's winner and rotate annually; the second will carry the name of the current year's winner and may be kept permanently. The winner will be selected by a panel of five judges, three of whom shall be members of the Northern New Jersey Chapter of QCWA; two will be prominent local amateurs. Presentation of the award will be made to the 1983 winner at the chapter's annual meeting, the evening of Friday, November 18, at the Burns Country Inn, Clifton NJ.

Rules

1. Nominations for the award may be made by any licensed amateur radio operator in northern New Jersey.
2. Nominees must be licensed amateur radio operators who reside in northern New Jersey.
3. Each nomination shall be accompanied by a statement (of 500 words or less) detailing the reasons the nominee is deemed worthy of the award.
4. All nominations must be received on or before September 1, 1983, by the chairman of the chapter's Elmer Award Committee.

Please direct all communications to: Gordon S. Gregory N2IN, 8 Winding Way, Denville NJ 07834; (201)-627-4426.

MISS AMERICA PAGEANT

The Southern Counties Amateur Radio Association plans to have a special-event station during the Miss America Pageant from September 13-17, 1983. Last year, they made 1,800 contacts in 49 states and 5 foreign countries with 800 confirmed. Due to more advance planning, they hope to surpass those figures this year.

NORTHWEST CORNER OF THE WORLD

The Wisconsin Valley Radio Association, of Wausau (Marathon County), Wisconsin, is pleased to announce the following special-event station: the second annual "If The World Is Round, Then How Come It Has Corners?"

Marathon County, Wisconsin, is located in north central Wisconsin. Besides being the largest county in Wisconsin (somewhat larger than the state of Rhode Island), it also contains the intersection of the 45° north parallel and the 90° west meridian. This point occurs near the city of Wausau, Wisconsin. This places Wausau exactly halfway between the North Pole and the Equator, and halfway between the Zero Meridian at Greenwich, England, and the International Dateline. It is the "Northwest Corner of the World."

The other three 45°/90° "corners" are located as follows: in the Pacific Ocean west of Chile, in the Indian Ocean southwest of Australia, and in a remote northern area of the Chinese province of Sinkiang, near the Mongolian border.

The Wisconsin Valley Radio Association will operate on the exact site of the 45° N/90° W intersection on September 18, 1983, using the club station callsign, W9SM. Operation will be from 7:00 am to 7:00 pm CDT. Frequency of operation will be dependent upon band conditions but will be 25 kHz up from the bottom of the General phone portion of whatever band is being used.

Send an SASE for a QSL card. Send an SASE and $1.00 for a certificate to: Wisconsin Valley Radio Association, Inc., Box 363, Wausau WI 54401.

UNIONTOWN PA

The Uniontown Amateur Radio Club W3PIE of Uniontown, Pennsylvania, will be operating a special-event station on September 24, 1983, to celebrate Fayette County's 200th anniversary. Operations will be conducted from 1300Z to 2100Z, on or about the frequencies of 7.235, 14.285, and 21.360 on SSB; also 146.52 simplex between 2300Z and 0100Z for local contacts. An 8 × 10 certificate will be issued for contacts made during these times. Please send a large SASE and QSL to W3PIE, c/o John T. Cermak WB3DOD, PO Box 433, Republic PA 15475.

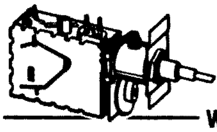
ANNO SANTO AWARD

The Anno Santo Award (Holy Year Award) is sponsored by the Rome section of the Associazione Radioamatori Italiani. The award is printed on deluxe paper and is about 19 × 13 inches (47 × 33 cm). It represents an engraving of St. Peter's Basilica. The same artwork is printed on the special QSL that will be used by most of the hams of Rome during the Holy Year.

WHITE TAIL DEER AWARD

The Mid-Michigan Amateur Radio Club has announced the first of a series of awards featuring the wildlife of Michigan. The certificate is available to all licensed amateurs and shortwave listeners. The White Tail Deer Award requires contacts with two Mid-Michigan Amateur Radio Club stations, or contacts with one MMARC station and three White Tail Deer Award certificate holders. For Novice applicants, the requirements are one contact with an MMARC station or one con

MORE GAIN
Than a Varactor UHF Tuner



$15.00 SATISFACTION GUARANTEED

Frequency Range 470-899 MHz Channels 14-83. Output Channel 3. Ch 2 or 4 Avail.

PART #B20 .... $15.00

WHAT'S IN IT?

To make a regular UHF tuner into a **GILCO HIGH GAIN TUNER**, each and every one of the following steps is painstakingly taken by a certified technician:

1. The first thing GILCO does is change the standard diode to a **hot carrier diode**.

2. The tuner's output is then measured on our JERROLD field strength meter and compared to a computer derived chart from which we determine the correct value coil to add across the IF output for ***maximum pre-peaked gain***.

3. The tuner is then fed a standard 10db 300 ohm antenna input and while monitoring the output on our HEWLETT PACKARD spectrum analyzer, the tuner is tuned to the desired channel and its oscillator is offset for the desired output frequency as follows:

Channel 2: 58 Mhz, Channel 3: 63 Mhz, Channel 4: 68 Hhz

We call this step peaking because the tuner's output looks like a peak on our spectrum analyzer and the highest point of that peak is actually adjusted for the desired output.

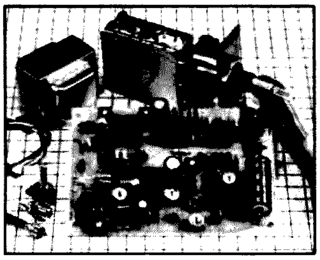
4. The last step is one more measurement on the field strength meter which is again compared to our performance chart to calculate the correct value of the second coil which is added to the tuners internal connections.

This procedure was developed by GILCO and it is our computer derived performance charts that make our tuner better, that's because ***almost every tuner gets a different value coil*** before it's peaked and again a different value coil after it's peaked. The combinations are endless and ***the way we determine the values is our secret...***

GILCO PARTS KIT & PRINTED CIRCUIT BOARD

- **Use with GILCO High Gain Tuner**
- **Requires NO Modification to Your Television**
- ***Individually Packaged and Labeled Parts Save Guesswork***

- The only tools required for assembly are: screwdriver, soldering iron, voltmeter. No drilling is required to the P/C board.
- This kit was designed to take advantage of the GILCO high gain tuner which means its circuitry is ***simpler and more efficient*** than those circuits that require inferior varactor tuners.



Pre-drilled, pre-screened, plated through the holes P/C board. All hardware, connectors, 22 page illustrated instruction manual, & Gilco Hy-Gain tuner. Kit assembles in just 4 hours.

FREE 22 Page Instruction Book included with each P/C Board or Parts Kit. This instruction book will guide the builder through every step of the assembly. ***Nearly every page is illustrated.*** With this instruction Book, estimated assembly time is 4 hours.

HERE'S WHAT YOU GET FROM GILCO

Part No. B21 Printed Circuit Board $17.00

1. This Printed Circuit Board uses ***only one jumper, others use nine.***
2. ***The component layout is screen printed*** on the component side of the P/C board.
3. The solder side of the P/C board is covered with high temperature solder resist. This prevents solder bridges.
4. ***Newest Addition:*** **the P/C board is plated through the holes.** This allows for easier and more positive soldered contact between the parts and the P/C board.

Part No. B22 Complete Electronic Parts Kit $80.00

All resistors (30), Potentiometers (1-5K, 3-10K), Panel Mount Potentiometer (10K), Electrolytic Capacitors (6), Ceramic and Mylar Disc Capacitors (35), Variable Capacitors (4), All Integrated Circuits (7), Voltage Regulator, Heat Sink, Diodes (4), IC Sockets (4-8 pin, 3-14 pin), Power Transformer (24V, 1A), Coil Kit with No. 26 wire (4), Speaker (4", 3oz.), Standoffs, Coaxial Cable, All Miscellaneous Harware, Etc. All parts are individually packaged and labeled.

All components including the Wire, Hardware, Coaxial Cable and Heat Sinks are included in the parts kit. This means your assembly time from start to finish is just 4 hours.

GILCO ACCESSORIES & AMPLIFIER KITS

#A02 New 2 stage, low noise, 28db gain RF amplifier kit .... Kit $18.00

#A03 New 1 stage, low noise, 14db gain RF amplifier .... Kit $10.50

tact with a White Tail Deer Award certificate holder. For shortwave listeners, the requirements are one MMARC station heard or one White Tail Deer Award certificate holder. A detailed list showing name, call, and QTH of the station or stations worked or heard should be accompanied by one dollar US to cover postage and printing costs. Payment may be made by cash, check, money order, IRCs, or USA postage cards, and photocopies of QSLs will be accepted. Contacts may be made over any period of time, so dig back through your logs. Also, note any special endorsements that you want on your award. Repeater contacts cannot be used, but satellite contacts can. Send applications and information to: Gary Lorenz WD8JFF, Awards Manager, MMARC, 3210 N. County Line Rd., Farwell MI 48622.

NEW AWARD FROM PARS

The Poway Amateur Radio Society (PARS) has announced that a handsome new certificate, known as the "Distinguished PARS Communicator," is now available. The certificate has been issued to promote amateur radio contacts between PARS members and the amateur community at large. To qualify for the PARS certificate, operators must contact 5 PARS members (25 for San Diego County residents) and then submit their list of contacts in log form with an SASE to: Operations—PARS, PO Box 996, Poway CA 92064.

ULSTER COUNTY AWARD

I received a very complimentary letter about our Awards column from Harold Twiss WA2RXF, who represents th Overlook Mountain ARC in Lake Katrin New York. In his letter, Harold enclose details of a very nice award being offere through his club.

This award requires applicants to co tact other amateurs residing in the Ne York county of Ulster.

To qualify, DX stations must conta two amateurs in Ulster County, whi amateurs in the continental US mu make three contacts. There are no band mode limitations, and there are no dat restrictions.

To apply, submit a list of contacts gi ing the usual logbook data in addition t the award fee of 50 cents or 4 IRCs t Harold Twiss WA2RXF, Country Lan Lake Katrine NY 12449.

WORKED A SHEBOYGAN AWARD

With activity on 10 meters at an all-tim high, now is your opportunity to earn th very attractive WAS (Worked A Shebo gan) Award.

All that is required is that a contact b made with any station in Sheboyga County, Wisconsin, on the 10-meter ban

To apply, merely send your logbook i formation to the Awards Manager, Sh boygan County ARC, Inc., Farnsworth J High School, Sheboygan WI 53081. As gesture, should you find that earning th award is impossible, why not drop the J High School a letter and arrange for schedule with one of their amateurs Their club station is K9ERO.

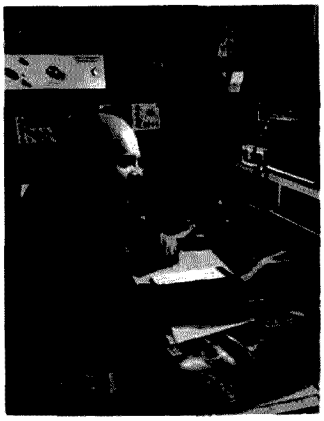
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



GREEN SELLS OUT

In a way, I suppose you might say that I sold out, but I plead guilty with an explanation.

It all started last spring when some chaps from one of the bigger banks called saying that they had a large foreign publisher who was looking to acquire something like my micro publishing empirette. I wasn't much interested because I enjoy what I'm doing more than anything else I can imagine. But what would it cost to listen, right?

So they came to visit and looked over our place. I showed them our growth in sales, which has run around 50 percent a year for the last eight years. They mumbled vaguely about $50 million, which I have to admit got my attention. I'd really never given much thought to what the whole mess might be worth.

The word that I was thinking of selling began to spread, and new suitors started calling every few days. The more I talked with these firms, the more I realized that this probably was a good time to merge with a larger firm so that I would have the money to invest in some new projects. I have never had much of a personal need for money, so selling out for a big bundle of cash had little attraction.

No, it would be worth merging if I could get the money to start magazines at a faster rate and thus be able to keep up better with the needs of the microcomputer industry. And I had an idea for a new type of magazine I wanted to try out. If it worked, I'd have a way to get perhaps 50 more like it going, each with expected sales on the order of $5 million a ear or more.

Then tl ɜre was my idea for a new type of school, a business/technical institute geared to the needs of the 80s. The more I thought about it, the more ideas for new divisions of Wayne Green, Inc., came to mind. With some cash available for getting these new businesses and publications going, we could step up our growth enormously. I did some sales projections and I could see us growing to a billion in sales within ten years just on the plans already in mind.

As I talked with the firms interested In merging, I found several of them excited about my ideas and plans. I'd had a good record of coming up with innovative ideas in the past, so there wasn't much skepticism about my new ideas. After all, I'd had the idea to start the first magazine for micros: *Byte*. And then I started the first system-specific magazine: *80 Micro*. And I'd pioneered mass-produced software. As I talked with people, I realized that I have a pretty good track record.

The final choice of a merger partner was most difficult. Several large firms put it bluntly: They needed me and I could name my price. Now I want to tell you, that is fantastic for the ego. I really wasn't Into shopping around for the highest offer because the difference between $50 million and $100 million means a lot less than the compatibility of the merger. And numbers like that don't mean anything, anyway; they're just very big numbers.

On May 22nd, I signed a preliminary agreement with Pat McGovern, the publisher of the

QSL OF THE MONTH

This month's QSL card winner depicts a nighttime scene from the nation's capital, viewed from the Virginia side of the Potomac River. The Lincoln Memorial is in the foreground, with the Washington Monument and the Capitol in the background. Tom Dorset WB4J makes this card distinctive by using lowercase letters for his callsign, giving a modern feel to this traditional scene. Opposite Tom's callsign, a faint moon looks serenely over the entire panorama.

To enter *73*'s QSL of the Month contest, put your card in an envelope with your choice of book from *73*'s Radio Bookshop and send it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries not in envelopes and without a book choice will not be considered.

"10. . .9. . .8. . ."

Be ready when the Space Shuttle Columbia *carries aloft the first astro-ham. Here's the best way to contact this historic DXpedition.*

Alan Kaul W6RCL probably said it best about a year ago when he wrote, "Get ready for the greatest DXpedition ever. An astro-ham in space on 2 meters." Alan, who produces NBC Nightly News for the west coast, did not pen those words for that vehicle. Rather, they were the lead-in to a 2-minute special report by Roy Neal K6DUE which aired on my Westlink Radio News Service.

It was a story that took the world of amateur radio by storm, and one which will hopefully unfold on September 30, 1983. That is the day when NASA plans to launch the STS-9 shuttle mission into orbit. On board the orbiter *Columbia* will be the European Space Agency's "Spacelab," manned by an international crew including Dr. Owen Garriott of the United States.

It is Dr. Garriott, the radio he will take with him, and the type of operation planned that will open a new chapter in space-to-Earth communications. Dr. Garriott is a ham—W5LFL. The radio is for the 2-meter amateur band, operates on FM voice, and with it W5LFL hopes to contact amateurs around the world, making this the first time any form of private radio has been used from space.

Background

If you think it's easy to convince NASA to let you operate an amateur station from one of their space vehicles, then try to get yourself permission to do so. In the case of W5LFL/Space Mobile, it has taken a decade and a half. The idea originated shortly before Dr. Garriott was rocketed into space to serve duty on *Skylab*. He had approached NASA with the idea of taking along a 2-meter radio back then, but it was nixed because of power requirements and other technical considerations.

Since that time, the thought of operating from space has stayed with Dr. Garriott, and several years ago with the assistance of members of the Space Center ARC in Houston (W5RRR) and NBC news correspondent Roy Neal, another proposal to carry amateur radio on a shuttle mission was made. The flight would be the STS-9 using the orbiter *Columbia* and carrying the ESA Spacelab. This time the response was positive, with General James Abramson giving the project the green light earlier this year.

About three years ago, two other amateur radio organizations, the ARRL and AMSAT, were brought into the planning of this event. As plans progressed, it was recognized that for the operation to be successful, it would take the full cooperation of amateurs around the world. A radio that could meet the critical requirements of the space shuttle was needed. Specific operating protocol had to be developed to ensure a maximum number of QSOs to be held in the allotted operating time periods. Publicity had to be planned. A QSL manager or bureau would be needed to handle the expected torrent of requests for commemorative cards, and much, much more.

It was obvious that only an organization with the resources of the ARRL could handle such a chore, besides which Dr. Garriott wanted due credit given to the League for its assistance in getting the groundwork for the mission put together. The ARRL has been unofficially involved since the beginning. From the outset, this has been billed as a joint ARRL and AMSAT goodwill operation in celebration of the 1983 World Communications Year, but to us on the ground hoping for a contact with W5LFL from space, it is far more than that.

The STS-9 Radio Equipment

There have been many questions asked about the type of gear that W5LFL will be using on the STS-9. It seems that every amateur has heard a rumor that it will be this HT or that one. Officially, the radio is described as a black-box transceiver supplied by the ARRL. But the ARRL is not building the unit. Rather, its design and construction were placed on open bid to interested radio-equipment manufacturers. About six, both domestic and foreign, initially showed interest.

That number dropped off a bit after the specifications for the unit were announced by NASA. The criteria for the radio are very stringent and include the provision that the equipment cause

CES INTRODUCES THE NEW 510SA "SMART PATCH"

The State of the Art Simplex Interconnect

Communications Electronics Specialties introduces the CES 510SA "Smart" Simplex Autopatch, with many important new features never available before: • Three digit control codes with user programming. • A sophisticated toll restrict provides positive long distance lock out. • Time-out and COR activity timers with warning beeps and digital programming. • Rotary or DTMF dialing. • Phone line in-use detector prevents interrupting a call in progress, and sends unique CW sequence. • Phone ring detection logic enables unique CW sequence. • Digital programming of the sample rate and width, and noise gate sensitivity control, for easy interfacing with most radios. Simple and direct connections to radio.

Options available: • Smart CW identifier with unique CW messages for each patch function. • FCC type accepted phone line coupler. • Special tone squelch kit to operate patch through repeaters.

CES

The 510SA—the newest advance in interconnect technology, from the innovators at:

absolutely zero interference to any other system on board while operating from the indoor antenna. The unit must be totally independent of the spacecraft's electrical system, yet be capable of producing at least 5 Watts continuous power for the duration of each operating period of 1 hour per day for 5 days. In addition, the unit has to be channelized to make it easy for Dr. Garriott to operate, with maximum receiving and transmitting efficiency from 144.9 to 145.8 MHz. All of this and more for the distinct pleasure of knowing that your radio has been selected to be the first in space and never really being able to prove it.

It was decided a long time ago that the term "black box" would be applied to the set by the ARRL, since it didn't want to find itself in the *de facto* position of endorsing the product of one manufacturer over another. Oh, we will all eventually know whose radio flew on STS-9. You can be sure that the manufacturer selected will take full-page ads in every amateur magazine to proclaim this, but you won't see an official endorsement from the ARRL, AMSAT, or anyone else in amateur radio directly involved in the mission. For the sake of objectivity and nonpartisanship, it has to be this way. The leaders of the amateur-radio community don't want to become involved in a "Tang" type of publicity campaign.

The unit itself will have three modes of operation. This is subject to change before this article goes to press, but this is what we have at this writing. Mode 1 will permit split-frequency transceive with Dr. Garriott transmitting between 145.51 and 145.77 MHz and listening for callers 600 kHz lower. It is not expected that this mode or mode 2, which is simplex operation from 145.51 to 145.77 MHz, will see much use (if any) during the mission. Rather, it is mode 3 that will probably be exercised the most. In this mode, the transceiver must be capable of transmitting on the same frequency range of 145.51 to 145.77 MHz, but will receive on an odd offset between 144.91 MHz and 145.49 MHz. Modes 1 and 3 will use 20-kHz inter-channel spacing, as will the channels for the simplex mode 2. More on this operation later.

The antenna will be inside the *Columbia* orbiter itself and will be an "indoor array" of some type affixed to the upper crew compartment window. Several types of antennas are being experimented with. One is a loop, another a printed-circuit resonator, and there are others. Development is taking place at the Johnson Space Flight Center and being done by NASA scientists and engineers. During the flight, *Columbia* will be flying upside down by Earth perspective and that window will be facing the ground.

What the QSOs Will Sound Like

Present estimates are that Dr. Garriott will have time for only about 500 or so QSOs while in space, so don't expect to be able to rag-chew or even speak directly with W5LFL. I hate to use the term, but what I am about to describe is going to sound like some sort of a DX list operation, with Dr. Garriott developing the list as he goes. The STS-9 orbiter, because of its sharp equatorial crossing angle (N to S, S to N), will place W5LFL in direct contact with a given geographic area for about 8 minutes on any given pass. *Columbia* will be traveling with a forward momentum of about 17,000 mph at about 160 miles altitude in what amounts to a sine-

wave pattern around the planet.

Keeping this in mind, and adding to it that during any given operating period the spacecraft will almost go full circle around the world, you can easily understand the constraints on individual QSO time. For this reason, split-frequency operation and some form of time-sharing between astronaut and terrestrial stations had to be established. When an operating period begins, you will hear W5LFL making a call-up that may be something like this:

"This is W5LFL Dr. Garriott aboard the US Space Shuttle *Columbia*. we are now approaching the west coast of the United States I'll be taking calls from the 6th call district only for the next minute this is W5LFL standing by."

For the next 60 seconds, Dr. Garriott will scan across his preprogrammed receive frequencies. During that time, ground stations (that's you and me) will simply choose what we feel is the best frequency for our use and transmit our callsign for one minute. During the next minute, Dr. Garriott will acknowledge the callsigns he hears and then announce the next zone he will be listening for. At this point, the whole process begins again and continues on a minute-by-minute basis until that particular hour's operating period has ended.

As planned now, Dr. Garriott will transmit on the even minutes starting at the top of the hour and will listen for calls on the odd minutes. Stations on the ground will have about a dozen uplink channels to choose from. Use of repeaters and remote-base systems is discouraged, and while some uplink channels may fall on known repeater output channels in the United States, a myriad of stations on the ground trying to capture a repeater to be heard above the throng will make a given channel useless. Therefore, repeater owners on affected frequencies might be wise to terminate the operation of their systems for the 10 minutes or so that *Columbia* will be within radio range each day.

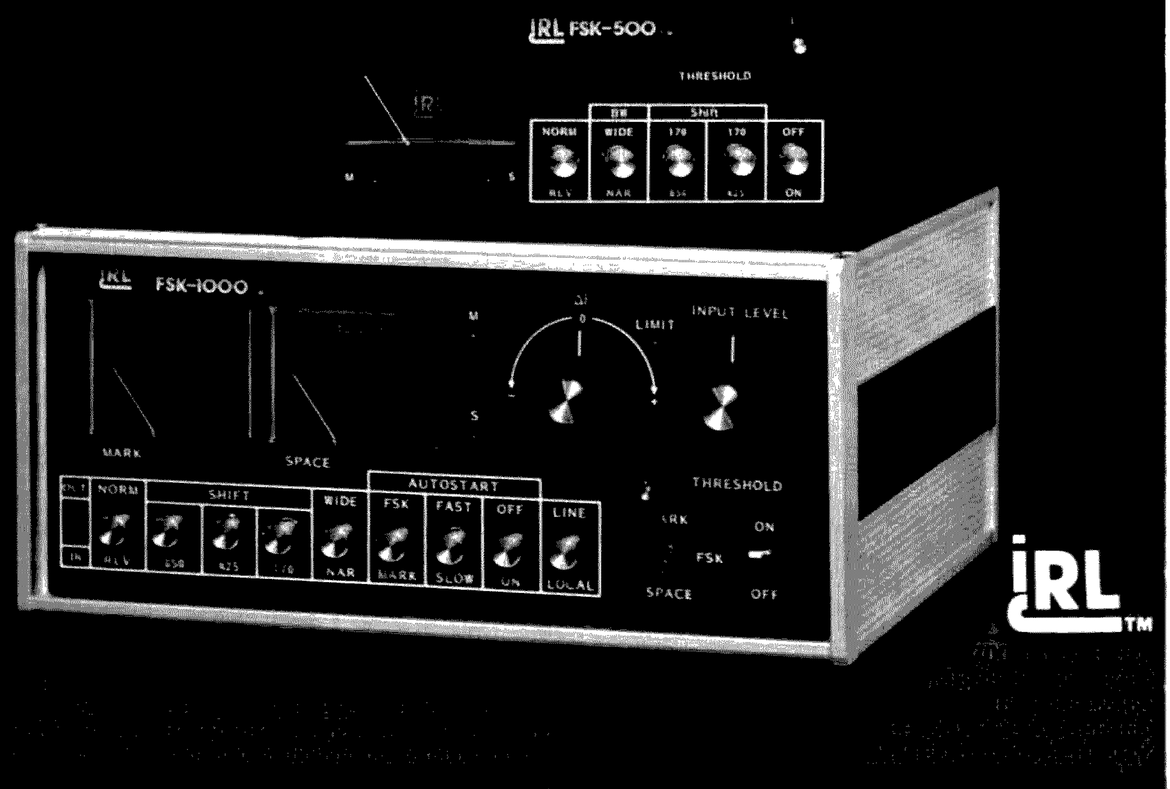
The channels selected for uplink were determined based on international spectrum utilization including ITU regions 1, 2, and 3. Dr. Garriott will not limit his contacts to US hams, but will acknowledge calls from the world over as he passes overhead. While this choice of frequencies may pose a bit of an inconvenience in some major metropolitan US cities where repeaters operate every 20 kHz in the lower subband, it is a choice compatible with the rest of the world. Now you can begin to imagine why groups the size of the ARRL and AMSAT had to be employed to coordinate the ground side of the operation. No one person could possibly do it by himself.

Your Station

Not every ham reading this will have a chance to contact W5LFL/Space Mobile. About 500 of you will be the lucky ones, but it will take more than a 1-Watt HT and a rubber duckie to get through. Stations that are equipped for the OSCAR series of amateur satellites and have the necessary expertise in making contacts through these birds will definitely have the upper hand.

If you do not have this expertise, then you are advised to steer clear of highly directional antenna arrays with small beamwidth. At 17,000-mph forward momentum, the STS-9 will not be in any one spot very long. In fact, unless your station is operating with the antenna under direct computer control with auto-tracking for both azimuth and elevation, any

THE RTTY ANSWER



sort of directional array will be a definite handicap.

AMSAT suggests that a horizontally-polarized turnstile-type antenna will probably provide the average amateur the best chance of making a contact. In lieu of this, any good-quality vertical antenna should suffice. The ARRL's *Radio Amateur's Handbook* should be consulted on design of a turnstile, since none for the amateur 2-meter band is currently marketed.

The recommended transmit-output power level is 10 Watts. Running higher power will only cause unnecessary interference to other ground stations and will gain you little. Remember, as with any DXpedition, Dr. Garriott—not you—is in charge of the operation. If there is too much QRM on a given channel because it is infested by the high-power boys, it easily can be bypassed. Dr. Garriott will only spend a few seconds monitoring any given uplink channel. And while we cannot stop anyone from running an amplifier, it is requested by all parties involved in the planning that this practice be avoided.

Because of the odd split between uplink and downlink, you will need a transceiver with split memory so that you can select your transmit frequency independently of the receive frequency. In lieu of this, two radios can be used, one for uplink and the other for receiving the downlink. Even an HT with a ¼-wavelength antenna may suffice for the latter, since Dr. Garriott will be easy to hear from almost 200 miles overhead. If you have an older, crystal-controlled radio sitting in the closet, it might be used for receiving by feeding a stable vfo signal of the proper frequency into the receiver's L/O chain. Designs have appeared in this magazine and elsewhere that might be readily adapted for the purpose. The receiver will then have to be realigned for maximum sensitivity in the region from 145.0 to 145.6. Again, super sensitivity of ground stations is not essential, since W5LFL won't be hard to hear.

So, then, in review: You will need a station running 10 Watts or so of FM on 2 meters with 20-kHz incrementation in the 144.91-145.49 band to uplink to Dr. Garriott. You will have to be able to listen for him on 1 or 2 frequencies in 20-kHz steps from 145.51 to 145.77 MHz. You should avoid highly directional antennas unless you are skilled in their use for satellite-communications purposes, and you should avoid the use of high power to make life easier for both W5LFL and the other ground stations who will be vying for contacts. Omnidirectional antennas in general, and the turnstile in particular, are recommended.

As the plans for Dr. Garriott's historic mission move forward, there will doubtless be many changes taking place. For example, the exact list of frequencies for you to use may not be known until just prior to liftoff. His daily operating schedule, which begins on the third day of the mission, will not be publicized until the vehicle is safely in orbit. It will be announced, hopefully a day before but possibly only hours before an operating period begins. Each operating period is subject to last-minute cancellation with little or no notice should some more urgent activity concerning the overall STS-9 mission itself come up.

While we in amateur radio probably consider W5LFL/Space Mobile as being very important, to the folks at NASA it is the lowest priority on the mission. We are their guest and no

more. If we handle ourselves with the proper decorum, we might be invited back again. If we make fools of ourselves, you can count on never being invited back in the door.

Since timely, up-to-the-minute information will be crucial, the planning of this has been included in the overall scheme. First, there is the AMSAT Launch Information Service Net that covered the successful AMSAT/OSCAR 10 launch on June 16. Readers are advised to keep an ear on their local AMSAT nets for further information on what type of network will be established for the STS-9

The League's W1AW will carry updates daily, but it is unknown if this will occur at regular times as published in *QST* or at any and all times applicable during the STS-9 mission. This will be announced by the ARRL shortly. Finally, the Westlink Radio Network's automated newsline in Hollywood, (213)-465-5550, will be devoted exclusively to information on the STS-9 mission starting September 1. This will be a weekly tape until September 29; one day prior to the scheduled liftoff of STS-9, it will be updated daily or whenever pertinent information is available. Hopefully, it will carry the day-to-day operating schedule of STS-9. Finally, the *ARRL Letter*, the *W5YI Report*, and *The Westlink Report* newsletters will carry the timely information that can be gathered before presstime.

Amateur magazines such as this, with their longer lead time of about 2 months, cannot bring you up-to-the-minute information on STS-9. We are doing our share by giving you as much background material and technical advice as we can. For up-to-the-minute information, you should consult one of the previously-mentioned news services starting about 10 days before the flight and

staying with it until the mission terminates.

Public Relations

The public relations of this first "Ham in Space DXpedition" have not been overlooked. As Steve Mendelsohn WA2DHF of CBS in New York has aptly pointed out, this will be one of the very few times when amateur radio will be in the news as the main event, not just the carrier of the message. For the duration of the STS-9/Spacelab mission, the eyes of the non-amateur world will be on us, in sharp focus and high-contrast living color, knowing the way that modern television journalism works.

To help plan for this, two teleconference meetings have been held. They were sponsored by the ARRL and hosted by Peter O'Dell KB1N of the ARRL Public Information Office. The first of these was a briefing primarily for members of the national/international press corps and included representatives of CBS radio and television news, NBC radio and television news, UPI, AMSAT, *The Westlink Report*, and the *W5YI Report*. After this session, another was held for the amateur-radio media and included participation of every major amateur publication and news service. Other such meetings are planned, including the possibility of a group interview with Dr. Garriott prior to the mission, if NASA gives the go-ahead for it.

Radio, television, and printed-media coverage of the amateur-radio aspect of the STS-9 mission is expected to be extensive. Pool video of part of the operation is expected to be supplied to the networks, so it's remotely possible that you might see your own contact being made on your own television screen. More likely, this video will be integrated into scheduled news programs on a tape-delayed basis, intercut with pictures of local hams trying to make the contact. Don't be too surprised to get a call from a local TV station asking if they can send over a crew to tape you making the attempt. A press kit to cover this and any other eventuality is being prepared by the ARRL for field distribution through its field organization structure. This writer and many others are contributors to it, and it will be very detailed on how you should handle this eventuality or any similar one that may occur. Contact your local ARRL Public Information Assistant or Division Director for more details.

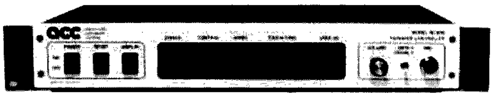
Finally, the ARRL is sponsoring the production of a new videotaped presentation entitled "Amateur Radio's Newest Frontier." It will detail the flight of STS-9, amateur radio's involvement in it, and the way in which our service performs a marriage between computer technology and space-age communications. Its producers are Roy Neal K6DUE and this writer; it will be taped in early July on location at the Johnson Space Flight Center, Marshall Space Flight Center, Kennedy Space Center, AMSAT's laboratory, and ARRL Headquarters. Editing will be done at CBS Television City in Hollywood with initial release anticipated around September 1 directly through the ARRL.

The hope is to have the tape in every school in the United States prior to the STS-9 liftoff. On termination of the STS-9/Spacelab mission, the master tape (1" type C for those interested) will be re-edited using actual NASA footage of Dr. Garriott operating from the *Columbia* and a second release will be made.

Also, the presentation will

RC-850 REPEATER CONTROLLER

A Breed Apart!



The RC-850 Repeater Controller is creating a New Breed of repeaters. Providing the ultimate in reliable, versatile communication, with the most advanced repeater autopatch available, and synthesized linking to other repeaters.

Its mailbox, informative ID and tail messages, and user signal diagnostics make it your group's "Information Center".

Plus two-tone paging, site alarms, and remote control functions. With remote metering to let you troubleshoot your system from home. Its built-in time of day clock and Scheduler have redefined the meaning of "automatic" control.

The RC-850 controller is remotely programmable with Touch-Tone commands, and is available with life-like synthesized speech for an ideal human interface. And it's upgradable through software so it'll never become obsolete.

be made available to television stations interested in airing it prior to or during the mission. Its running time will be between 10 and 15 minutes, with availability on the following tape types: Broadcast 1" type C, Broadcast 2" Quadraplex, 3/4" U-Matic, VHS-SP Speed, and Beta II.

The tape will be recorded using the NTSC 525-line standard, but both PAL and SECAM dubs will probably be made available at additional cost.

Again, contact the ARRL directly or through your Division Director for availability of this tape. Initial copies will be distributed on both U-Matic and VHS to all directors as soon as the project is completed. Please do not bother them prior to early September, since I know that it won't be finished until around that time.

Summary

Barring the unexpected, such as a delay in the STS-9/Spacelab mission itself, the US Space Shuttle *Columbia* carrying the ESA Spacelab will be launched into orbit from the NASA facilities in Florida on September 30. Sometime on October 2, at an exact time to be announced, the amateur-radio aspect of the mission should begin. Dr. Garriott will be operating as W5LFL, either Portable *Columbia* or Space Mobile. He will operate for one hour per day in the frequency span discussed earlier. Ground acquisition from any given geographic location will be about 8 minutes per pass. It is estimated that Dr. Garriott will be able to make about 500 contacts during the mission.

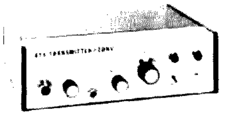
Finally, there is the all-important QSL information. ARRL Headquarters will be the QSL manager for the operating event. Since, as stated, only about 500 of you will make that lucky contact, a decision has been made to honor SWL reports that can be verified against operating times contained in both the written and voice-recorded logs. A system has been developed to prevent dual contacts while at the same time make legitimate QSLs for contacts made with STS-9 easy to prove. However, this also means that anyone, ham and non-ham alike, who sends a verifiable report to ARRL Headquarters will be eligible to receive a commemorative card in return.

This information is already being widely disseminated by SWL programs on many international shortwave stations and will probably be reported by the US mass media during the flight. The ARRL staff may be burning the midnight oil on this one for many days to answer all of the QSL requests.

There, then, is the story of what to expect on the STS-9/Spacelab mission. Again, I have to stress that much of this is subject to change with little notice. The best way to keep up to date is by turning to one of the daily, weekly, or bi-weekly amateur-radio news operations mentioned earlier. During the mission itself, one of the amateur-radio broadcast services supplied by the ARRL, AMSAT, or Westlink will be your best source of information since they can literally update at a moment's notice. In the meantime, we trust that many of you will enjoy the aspect of getting prepared to try to contact Astronaut/Dr. Owen Garriott W5LFL on 2-meter FM as he spins around the world. Whether you make the contact or not, getting ready for the event will be half the fun. Hearing W5LFL from space and knowing that he is one of ours will be the other half. Making a contact is literally the frosting on the cake. ■

COMPLETE READY-TO-USE SYSTEMS

ATV TRANSMITTER/CONVERTER



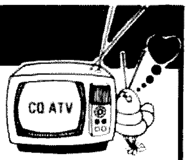
$399

TC-1

★ High resolution and color video
★ 10 watts output
★ Broadcast standard sound
★ Tunable downconverter and preamp

Connect to the antenna terminals of any TV set, add a good 450 MHz antenna, a camera and there you are . . . Show the shack, home movies, computer games, video tapes, etc.

ATV DOWNCONVERTER



SPECIAL SUMMER SALE

For those who want to see the ATV action before they commit to a complete station, the TVC-4 is for you. Great for public service setups, demos, and getting a buddy interested. Just add an antenna and a TV set tuned to CH. 2, 3, or 4 and plug in to 117 volts a.c. $89.00

TVC-4

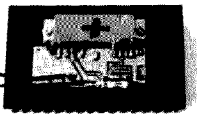
TVC-4L extra low-noise version . . . ~~$105~~ . . $99 delivered in USA

MODULES

TXA5-4 Exciter/Modulator . ~~$89~~ . $85.00 ppd.
Wired and tested module designed to drive PA5 10 watt linear amplifier. The 100 MHz crystal design keeps harmonics out of two meters for talk back. Video modulator is a full 8 MHz for computer graphics and color. Requires 13.8 VDC reg. @ 70 ma. 80 mw output power. Tuned with crystal on 439.25, 434 or 426.25 MHz.
Dual frequency model available . . ~~$115~~ . . $110.00 ppd.

TVC-2 ATV Downconverter . ~~$55~~ . . $45.00 ppd.
Stripline MRF 901 preamp and double balanced mixer digs out the weak ones and resists intermod and overload. Connects between UHF antenna and TV set. Output channels 2 or 3. Varicap tuner 420 to 450 MHz. Requires 12 to 18 VDC @ 20 ma.
Extrasensitive TVC 2L with bipolar preamp (.9 dB NF) . . . . . . ~~$68~~ . . . . $59.00 ppd.
Supersensitive TVC 2G with GaAs Fet preamp (.5 dB NF) ant. mount . . . . $79.00 ppd.

FMA5 Audio Subcarrier Generator . $29.00 ppd.
Puts audio on your camera video just as broadcast does at 4.5 MHz. Puts out 1 V p-p to drive TXA5. Requires low Z mike 150 to 600 Ω and 12 to 18 VDC @ 25 ma. Works with any transmitter with 5 MHz video bandwidth.



PA5 10 Watt ATV Power Amplifier . $89.00 ppd.
The PA5 will put out 10 watts RMS power on sync tips when driven with 80 mw by the TXA5 exciter. 50 ohms in and out plus bandwidth for the whole band with good linearity for color and sound. Requires 13.8 VDC reg. @ 3 amps.

Let P.C. put you on the air and SAVE!
All four modules —
Complete System price $235.00
SAVE $27.00 over price if purchased individually

Call or write for our complete catalog of specifications, station setup diagrams, and optional accessories which include: antennas, modulators, test generators, cameras and much, much more. See Ch. 14 1983 ARRL Handbook.

TERMS: VISA or MASTERCARD by telephone or mail, or check or money order by mail. All prices are delivered in USA. Charge orders normally shipped within 24 hours. Personal checks must clear first.

Join the Packet-Radio Revolution

Get error-free, high-speed communications. Packet radio's chief architect, WA7GXD, explains what it is and how it works.

Lyle Johnson WA7GXD
c/o Tucson Amateur Packet Radio
PO Box 22888
Tucson AZ 85734

Radio amateurs in Canada, Sweden, and the United States have recently been experimenting with a new system of communications that:

- can provide 100% copy under adverse band conditions (QRN),
- is virtually immune to interference from others on-channel (QRM),
- typically runs at about 1200 wpm (and can go *much* faster),
- is highly efficient of spectrum use,
- ". . . contribute(s) to the advancement of the radio art" (FCC Rules and Regulations, Part 97.1(b)—Basis and Purpose), and
- is inexpensive (surprise!).

This mode is called packet radio, and it opens the door to a new world of computer-based communications for the amateur community.

Imagine having a QSO with an amateur a continent away via a low-power 2-meter FM rig, or handling emergency traffic without worrying if you correctly copied the spelling of Solzhenitsyn, or leaving a message at a friend's shack if he is out. Then there are possibilities for bulletin-board systems, remote programming of computers, file transfers, and even multi-player computer games! The list of potential applications goes on and on.

This article is written to give the reader a practical look at packet radio, including a description of the equipment needed to use this new communications mode. Subsequent issues of *73* will carry details on hardware, software/protocol, and application. While the reading should prove interesting, the application of packet radio in *your* ham shack is the primary goal.

What Is Packet Radio?

Packet radio is a method of communications that encodes information digitally and in such a manner as to virtually ensure error-free copy at the receiving station. While this is quite a step forward from the present vulnerability of amateur radio operations to such things as QRM and QRN, it is only part of the picture. Packet-radio techniques also provide efficiency in spectrum usage by packing multiple calling and working channels on the same frequency.

If you've ever operated RTTY, you are very aware of the problems of selective fading, static crashes, and so forth—garbled copy is the usual result. The solution to selective fading generally means clever TUs and/or diversity reception, and this usually implies either a great deal of time or money or both. ASCII adherents will no doubt confess that they, too, are subject to the same problems. In fact, many RTTY operators have resisted switching to ASCII for this very reason.

In RTTY operation, operators will typically call a CQ on a calling frequency, then QSY to a working frequency to carry on their QSO so that other RTTYers may use the calling frequency. If a number of stations attempted to hold independent QSOs on the same frequency, chaos would result.

Packet radio overcomes the first of these problems by employing a technique called "handshaking," along with a computed error-detection value called a "Frame Check Sequence" (FCS) to ensure data integrity. The sending station expects an acknowledgment (ACK) to its transmission within a certain period of time or it retransmits. Upon accurate reception of a packet, the receiving station sends this ACK and the sender then continues about its next task. The handshake is done automatically.

Due to the structure of a packet, which contains certain information regarding the destination station, multiple users can be accommodated on a single frequency, holding separate QSOs without causing noticeable interference to each other! This means that the calling and working frequencies may be the same. This ability to selectively receive messages

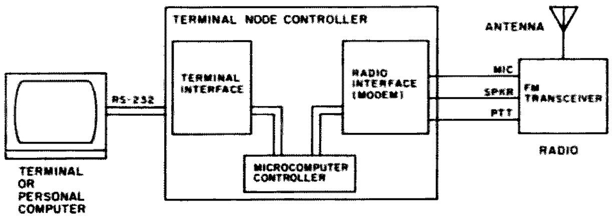

Fig. 1. Typical packet-radio equipment.

from a packet station on-channel is called "connectivity" and is a major contributor to the efficiency of packet radio.

Packet radio also takes advantage of the fact that most communications are "bursty." This simply means that a user does not require the entire channel bandwidth most of the time. Consider an operator typing a message to another station. It may take him as little as 10 seconds or as long as a minute to type a line, but it takes packet radio less than a second to get that data out. The packet system operates in bursts and leaves the dead time available for other packet stations (time-domain multiplexing). On a lightly-loaded channel (only a few users), you may not even be aware of the other stations! On a heavily-loaded channel, you may notice an increase in delay time before getting your reply back. Again, the packet-radio equipment takes care of all of this for you, automatically.

While packet radio requires the use of a computer-based controller at each station, it does not require that each operator be well-versed in computer technology, nor that the operator be a programmer. In fact, it does not require that the station have a personal computer; just a terminal will do.

Requirements

There are four primary components in an amateur packet-radio station: (1) a licensed amateur radio operator, (2) a user terminal, (3) a Terminal Node Controller (TNC), and (4) an amateur radio station.

Operator—The amateur operator is you! No special training in computer science, electronic engineering, nor digital communications is needed. All that is required is an interest and a little time. Packet radio does not run your station;

A complete packet-radio station. The TAPR TNC is below the HT.

you run it. (Note that amateurs possessing personal computers and a certain amount of expertise may be able to program their computers to control their packet stations.)

Terminal—The user terminal can be as straightforward as a simple Cathode-Ray Terminal (CRT), a personal computer, or an ASCII-speaking TTY, or it may be as complex as a commercial computer installation. A keyboard should be available for the operator to enter messages and to control the station. A screen or printer should be available to present information to the operator. No doubt, some packeteer will design a speech-synthesizer interface and use a speaker for output! (After all, our radios talk to us now, don't they?)

Most terminals, like RTTY and ASCII systems, encode the characters they send in an asynchronous format. This means, due to the "burstiness" of typing a message, that each character has a little flag to mark starting and ending points. The method employed is to encode a single space before the character and end the character with one or more mark value levels— see Fig. 2. This way, whenever a character is started, a transition from mark to space occurs. This, along with some timing information, makes the data easily decodable. In the case of RTTY, 7½ "bit-times" are used per character, and ASCII uses 10 or 11, depending on the baud rate (note that a baud and a bit are not the same thing, but in amateur use, one bit per baud is encoded, so the terms have become blurred.

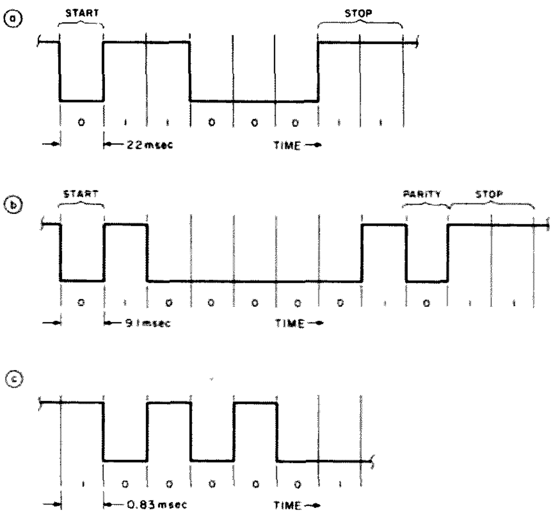

Fig. 2. (a) Typical RTTY (Murray) code for letter "A", 60 wpm. Note that in asynchronous formats, as used by amateurs, each character has one start and one or more stop bits. (b) Typical ASCII code for letter "A", even parity, 110 baud. (c) The ASCII letter "A" within a packet at 1200 baud. Note that a 1 is sent as "no change in state" while a 0 is sent as "a change in state." This is referred to as NRZI (non-return to zero, inverted) coding and is used by virtually all packet stations.

If you have a terminal or computer, you can use it. If not, terminals and computers that use TV sets for the display are readily available for less than $100. Nothing complicated is necessary.

Terminal Node Controller—The TNC is a device which connects the terminal and the radio system together. One port connects to the operator's terminal (or personal computer), communicating via the asynchronous serial or parallel method required by the terminal. (Note that the terminal baud rate has no relationship to the packet-channel baud rate.) The TNC converts the asynchronous data stream from the terminal into packets and vice versa—see Fig. 3.

The header contains an address to indicate where the packet's going and control information telling the network certain details regarding the packet. The FCS calculation ensures the integrity of the data, and flags mark the beginning and end of the packet.

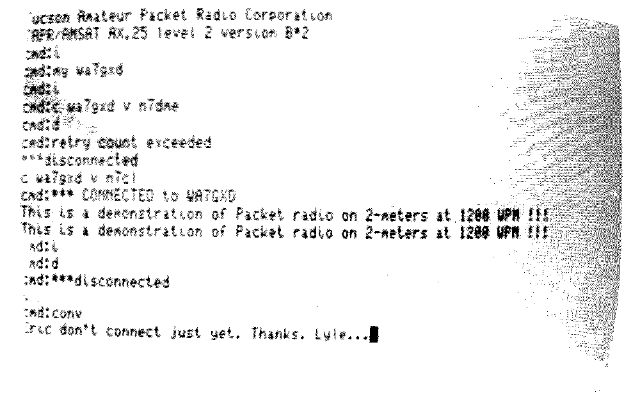
The other port of the TNC is the radio interface, which connects to the microphone audio, PTT, and speaker/phone audio lines. The modulation method most often used in packet radio is AFSK. This simply involves the application of one of two tones

to the microphone input on a voice-grade radio, one tone corresponding to a mark, or digital 1, and the other to a space, or digital 0. By switching between these tones, the data is passed to the radio, which handles it like any other audio signal. The receiving station then decodes the audio tones coming from the speaker or headphone connector on the radio and recovers the data, which is then processed. The advantage to this method is simplicity; the disadvantage is the use of a wider-than-necessary channel.

RTTYers will recognize this method since they have used it for years. They will also recognize the need for a terminal unit (TU), a device used to translate between the logic levels (data) and the tones. In packet radio, the TU is called a "modem" (Modulator-DEModulator) and serves the same function. (Note that some TNCs have the modem built in, while others require the use of an external modem.)

The usual packet-radio modem operates at 1200 baud (about 1200 wpm) and uses tones of 1200 Hz and 2200 Hz. This particular combination of tones is also used in the Bell 202 standard, which allows compatibility with surplus modems. In fact, some of the first packet stations used surplus 202 modems. Note that the tone combination is the only feature needed in a packet-radio modem to ensure compatibility with 202 users. The other aspects of the 202 standard (handshaking, timing, reverse channel, etc.) are not used in the rf environment.

Radio—The radio system can be whatever you have. Most packeteers use a 2-meter FM rig, such as a handheld or even a simple crystal-controlled "hamfest special." In light of the increased channel efficiencies that can be obtained with specially optimized radio design, we can expect to see rigs designed especially for packet radio in the near future.



High-speed transmission is possible with packet radio.

Note that the AFSK tones used in packet radio aren't compatible with the audio-frequency response of some radios: If the 2200-Hz tone is too severely attenuated, minor surgery may be required on the radio itself. With this one limitation, a radio suitable for voice communications can also be used for packet radio. (Duty cycle is not a factor, due to the previously-mentioned burstiness of a packet.)

In addition to the radio, an antenna system and a power supply for the radio are necessary.

Why Use a Terminal Node Controller?

The heart of a packet-radio station, next to the operator, is the TNC. The TNC is actually a special-purpose microcomputer, and it contains the necessary programs (software) to handle the radio, pass information between your station and other packet-radio stations, connect or disconnect your station from other stations, and so forth. These functions and the way they are implemented are part of packet "protocol." While protocol is much more than just the above, the job of the TNC is to effectively implement the protocol.

Many potential packeteers ask why a TNC is needed if they already have a personal-computer system. It doesn't appear too efficient in terms of dollars, at least at first glance. Indeed, there are some stations using packets that have modified their personal computers to act as TNCs, with varying degrees of success. The problems arise from two primary sources: protocol and real-time programming.

Protocol—Protocol is defined by Webster as "the highly formal procedure in official society." While packet radio is not an official society, it does require very formal, precise, well-defined, and (at least locally) standardized procedures in order to transfer data reliably.

In order for a number of stations to be on one frequency at one time with a variety of transmissions, ACKs, and so forth all going on, a computer network, not unlike a typical amateur net, must be established. This must be done rapidly and—in typical net fashion—according to procedures. If a station fouls up, it can cause a lot of confusion on the net. Stations must be able to check in and out of the net at will. The entire system becomes highly complicated, and the effort required to program the protocol is substantial. To handle these procedures, special hardware is needed, not found on any presently-made personal computers. The TNC is designed to handle all of the physical protocol (radio and terminal interfacing) as well as local networking.

Programming—Most computer hobbyists are familiar with some version of the Basic language and do much, if not all, of their programming in it. Calculation of an OSCAR satellite position, logbook entry, and other typical amateur applications run just fine in Basic. Basic is usually implemented as an interpreter, which slows things down during execution but allows the computer system to be interactive ("user-friendly") during programming sessions. To speed up things that must occur quickly, such as graphics or special I/O, some programs resort to assembly-language routines.

In packet radio, the TNC is required to perform many simultaneous tasks. It must check for activity on the frequency, examine all messages for certain data, accept operator input in the form of messages and commands, output data to the operator, handshake, initiate and respond to control within the network, perform FCC-mandated CW ID at prescribed intervals, ACK to certain transmissions, determine if some other packet-radio station interfered with its transmissions (called collision detection), and so forth. This is enough to keep one microprocessor very busy, especially at high data rates. To also be refreshing a video display, doing disk accesses, and handling general-purpose computing is beyond the ability of most personal-computing systems.

The type of software required to do this multitasking is different than normal software, and it requires a very different approach in design than that required by other types of programs.

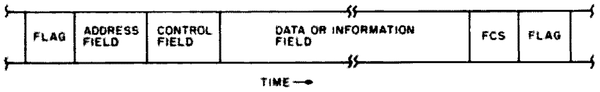


Fig. 3. A typical packet frame. Flag=01111110=1 byte. ADDR=1 to 24 bytes (protocol dependent). CNTL=1 or 2 bytes. DATA = 0 to 128 bytes typical. FCS = 2 bytes. Flag = 01111110 = 1 byte. All bytes are sent least-significant bit (LSB) first except the FCS, which is sent most-significant bit (MSB) first.

Most personal computers are not designed to support this sort of programming, nor to efficiently support the special type of interrupt-driven hardware systems needed to run in this sort of real-time environment.

In many commercial-computing systems, multiple CPUs are employed to speed things up—a technique called multi-processing. A TNC gives the amateur with a personal computer some of the same benefits. While your computer is doing disk I/O, the TNC can be doing what it must do to support the packet-radio activity. The TNC, then, is nothing more than a "smart" peripheral device for your personal computer, much like a disk drive or a printer. It does its task well, allowing your personal computer the time it needs to do its general-purpose tasks well.

What Is a Packet?

Again referring to Webster, a packet is "a small, compact bundle or portion." In packet radio, messages are broken up into small pieces and sent to the receiving station where the pieces are put together to rebuild the message. Naturally, some information is appended to the message so the receiving station will be able to sort things out. On a busy channel, there may be packets flying around between dozens of stations, but only a few are for you.

The operator generally just types in the message he wishes to send. Once the TNC has been told where to send the message, it starts breaking the text into packets which are then sent out on the network. While the size of a packet may vary, most are limited to 128 bytes (or characters, if sending text information) in the data field to allow channel access by multiple users. Typically, when the operator hits the RETURN or ENTER key on his terminal, the TNC formats and sends a packet. Thus, as the operator types the message, the receiving station immediately displays it.

Since packet radio is designed to handle any form of digital data (not just ASCII or Baudot, but also binary, EBCDIC, or whatever), a special method of formatting the data is employed. Most packet systems use a protocol based on High-Level Data-Link Control (HDLC) standards. HDLC is a Bit-Oriented Protocol (BOP) that enables the "transparent" (unmodified) passing of information within the system. One of the nice things about using HDLC is that the complex functions it uses to do its tasks are available integrated on a single large-scale integration (LSI) chip, which reduces the complexity of the TNC hardware and software, as well as TNC cost.

A packet is enclosed in an HDLC *frame*, which may be represented as shown in Fig. 3.

The *flag* is something the HDLC controller looks for (when receiving) or adds (when transmitting) to the packet to mark the beginning of a packet frame. It is a totally unique pattern of 1s and 0s for easy detection.

The *address field* contains information as to where the packet is being sent and possibly who sent it. Some schemes use the amateur callsign in this field (14 or more bytes), while others use a mapping system that requires only 1 or 2 bytes. Don't worry about how packet radio can support different addressing methods and still allow the stations to communicate—this is handled by the protocol and will be explained.

The *control field* tells the network certain things about the packet and includes sequencing, acknowledgment, and other control functions. This field may be one or two bytes in length.

The *data field* contains the actual message being sent. Unless the message is less than one packet in length, multiple packets will be required to send it, due to the current 128-byte data-length limit. The information in the data field is almost always user-provided.

The FCS provides the receiving station (node) with the information it needs to determine whether or not the data is valid. If the FCS calculated by the receiving node doesn't match the FCS it receives from the sending node, the receiving TNC throws away the packet.

The packet is closed by a second flag.

The flags, address field, and control field are all generated by the TNC and are used within the packet-radio network to implement the protocol used. The operator does not need to concern himself with the coding of these fields to use packet radio since the TNC does it all for him.

Since HDLC utilizes flags to mark the beginning and ending points of the entire packet, it is very inefficient to further require that each chararacter also have flags, so packet radio uses a synchronous protocol, removing the start and stop bits. This reduces the length of Baudot characters to only 5 bits and ASCII characters to 7 (parity is redundant due to the FCS). This means greater on-channel throughput.

How Is a Packet Network Organized?

At present, packet radio consists of several unconnected local area nets (LANs) that usually run on 2 meters or 220 MHz. Since this implies local coverage, it is only necessary that a station use the protocol being used in its vicinity. The advantages here are many, including the fact that it allows widespread experimentation with protocol optimization. This in turn leads to more efficient operation and allows each group the freedom to try various approaches for their own unique requirements.

An LAN may include a packet repeater, although using a repeater is not always necessary. The time-sharing nature of packet radio allows using a half-duplex (single-frequency) repeater. No splits or cavities are needed, so any packet-radio station can be a "digi-peater." Having a station act as a digi-peater requires no special effort on the part of the operator, who may continue to use it as a standard packet-radio station. Further, a normal full-duplex, split-frequency repeater could be used.

Naturally, VHF is limited in coverage (no one has successfully had a packet QSO with moonbounce yet), and most packeteers would like to communicate with others in other LANs. To this end, several packet stations are becoming operational on HF, and the unique challenges presented by HF operation are being met. However, another mechanism is being explored, called gateway operation (see Fig. 4).

A gateway station is a good example of shared resources, another packet advantage. To communi-

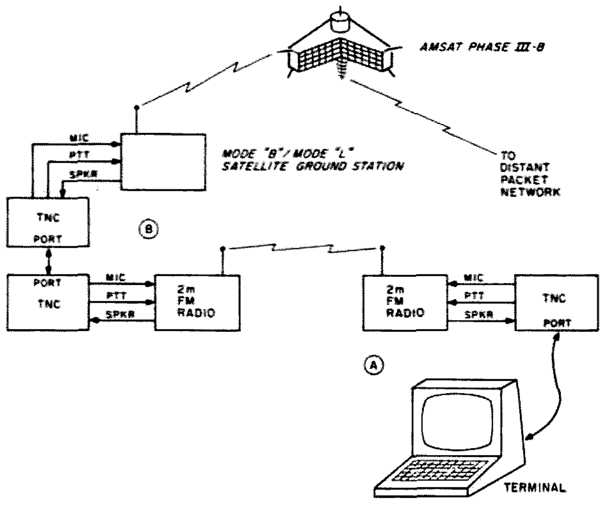

Fig. 4. Typical packet gateway system. Station A uses a simple 2-meter HT. Station B provides linking to other packet networks via satellite. Similarly, an HF link could be established.

cate outside the LAN, a gateway station receives the packet and does a "link" via a gateway channel and with another protocol (actually another layer of protocol). It translates the LAN protocol into the protocol used by the inter-network linking system. The gateway at the receiving end retranslates the protocol into its LAN protocol. Due to the continuing experimentation that is being conducted within packet radio, it is likely that the gateway system will be used for a long time.

Gateway stations allow the user in an LAN to communicate with other packet-radio stations far beyond his normal range. To allow this, three primary gateway paths are being developed:

TERRACON will be a high-speed UHF and/or microwave-based linking system that will form a so-called backbone network. This will enable any packet station to communicate with any other packet station that is also linked into TERRACON. This system could handle the bulk of long-distance packet-radio communications in North America, and it may find its way into other high-population areas such as Europe. Packet groups are working on this development; it will probably be a few years before a useful system is implemented, and a few more years before it links the continent.

AMICON is AMSAT's (Radio Amateur Satellite Corporation) initial Phase IIIB satellite-based network that will allow the linking of LANs via gateway stations equipped to use this high-orbit satellite. When working, AMICON will allow both intercontinental linking and connection with isolated areas. High data-rate experiments are now being planned for the 23cm/70cm (Mode L) translator aboard Phase IIIB that could point the way for a special high-speed packet-radio transponder package aboard a future AMSAT satellite.

SKIPCON is AMRAD's (Amateur Radio Research and Development Corporation) acronym for an HF-based network of LAN gateways. Due to the vagaries of HF propagation, data rates will be slower here, on the order of 50 to 600 bits per second with forward-error-detection and -correction protocol to ensure data integrity and minimize retransmission. Experiments have been conducted with these techniques since the winter of 1981-1982.

COMMON PACKET-RADIO ABBREVIATIONS

ACK—An acknowledgment from the receiving station indicating that the data was received correctly.
BOP—Bit-Oriented Protocol. This method allows unmodified transmission of information.
CRT—Cathode-Ray Terminal.
FCS—Frame Check Sequence. Method of detecting reception errors.
DLC—High-Level Data-Link Control. This is a BOP protocol which most packet-radio systems use.
LAN—Local Area Network. A network of stations in close geographic proximity.
TAPR—Tucson Amateur Packet Radio.
TNC—Terminal Node Controller. Connects the terminal to the radio system and implements packet protocol.

Where Can I Get a TNC?

At present, there are two TNC designs in common use: the Vancouver TNC and the TAPR TNC.

The Vancouver board is produced by a Canadian group called the Vancouver Amateur Digital Communications Group (VADCG), a nonprofit organization. VADCG is a pioneer in packet radio (the DOC authorized packet use in 1978), and the VADCG TNC is widely used by packeteers. This TNC is supplied as a "bare board." It requires a 4-voltage power supply, an external modem, and the necessary parts to populate it.

Notes are included in the instruction sheets that come with the board for designing the power supply, and VADCG makes a modem kit that is specifically designed for radio use.

The Vancouver TNC design is based on the Intel 8085 CPU and 8273 HDLC controller, 4K bytes of 2114 RAM, and 4K bytes of 2708 EPROM. An 8250 (for serial port) or an 8255 (for parallel port) is needed to interface the station terminal. Contact VADCG or other groups using this TNC for software. It is up to the user to work up the actual radio interface.

A group of amateurs met in Tucson in November, 1981, and decided to get involved in packet radio. Since many in the group were microprocessor hardware-design engineers, as well as real-time programmers, they decided to form a nonprofit organization and design a TNC with the modem, radio interface, and power-supply (exclusive of transformer) circuitry on a single board, for significant cost savings over existing designs. This resulted in the formation of Tucson Amateur Packet Radio (TAPR), a nonprofit corporation, and the development of the TAPR TNC.

The TAPR TNC is based on the 6809 microprocessor and can hold a total of 48K bytes RAM and ROM on the board. It uses the 1933 HDLC chip (fully compatible with the 8273 HDLC format—aren't standards nice?) and has both serial and parallel ports on the board for terminal or computer interface. The TAPR TNC is assembled, tested, and calibrated with all software in place and includes circuitry to interface to most radios. Software sources are listed in the manual that comes with the TNC for running in popular personal computers (to make them act like terminals), along with hardware interconnection information.

I would like to express my sincere thanks to Den Connors KD2S and Chuck Green NØADI for their comments, criticisms, and technical advice. ■

Be a RTTY Rembrandt

Put that award-winning shine on your RTTY pix with these tips from a RTTY artist's sketchbook.

Alfred La Vorgna WA2OQJ
21 Kuhl Avenue
Hicksville NY 11801

As I always liked art as a hobby, it was natural for me to adapt to RTTY art when I was bitten by the RTTY bug. Knowledge of art techniques need not be a requisite to the creation of good RTTY art. For the benefit of the few who may not know, RTTY pix is the transformation of any picture into a similar image us-

Preparing the cartoon for RTTY.

Close-up of typewriter technique.

The author with a pre-drawn cartoon, set up for RTTY transfer.

The author checking a completed picture.

ing only the upper- and lowercase printout of a hard-copy RTTY machine for transmission on the ham bands. There are new concepts being introduced with the use of computers, but that is an innovation that will develop in a class by itself.

When selecting a picture for copying, select those that have a minimum of detail and are of a north and south composition. Horizontal work is done occasionally, but the vertical format is much easier considering the direction that the paper is flowing from the machine, be it an old Model 19 or a later Model 28. There are many cartoons being transmitted on the bands because of the simplicity of design and elongated format.

Most RTTY artists select a picture from a magazine or newspaper and simply photostat it for insertion into the machine for reproduction by typing over the image. This usually works quite well except for the difficulty of obtaining an image that is long enough. I prefer to use the box method of enlarging as it gives more control over image dimension. Another method is to utilize the artist in the family to make a long skinny drawing. If you are not blessed with such an artist, fear not. You need not be a great artist to accomplish this task.

The typed area on most Teletype® machines averages about seven and one-quarter inches across with a total of 73 characters. Therefore, use seven inches as the width measurement and the up-and-down measurement is unlimited. Pull out five feet of paper from the roll and square it into one-inch spaces allowing the same space on the left-hand margin that your machine allows. Find an illustration that is at least four times longer than it is wide. Cartoons are suggested for early work. Divide the distance across the selected picture into seven segments. The size of one of these segments will be the dimension of all your squares. Now simply copy whatever is in each segment into the one inch squares on your paper. Eliminate as much detail as possible. Pay no attention to the jagged appearance. When you have completed all the squares, you will retrace the rough lines into smooth lines.

Step back from the completed drawing and visualize the dark, light, and medium sections and decide which letters or figures will best accomplish your objective. Try to hold overlines to two passes as this should prove sufficient for most work. Contest rules usually limit overlines to three.

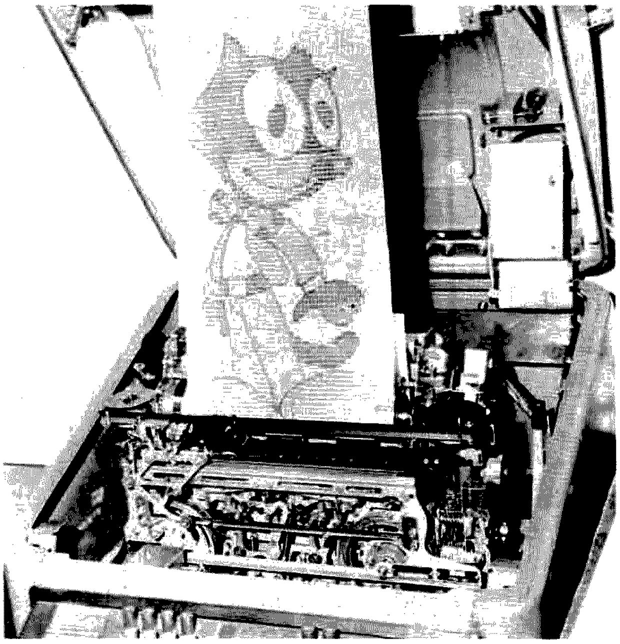
Now we come to the biggest time-saver of all. If you have or can obtain an old vintage typewriter, you will discover that most of them have the same spacing as the RTTY machine. Many old typewriters can be picked up at attractive prices.

If you decide to buy a typewriter, bring along some typed copy from your radioteletype machine. Make a similar copy on your intended purchase and hold both copies up to the light for comparison. Let the light shine through both sheets held together. If only half a letter is lost by the end of a line, you have a good selection, but line-to-line spacing must be very close. Small differences can be made up as I will explain later.

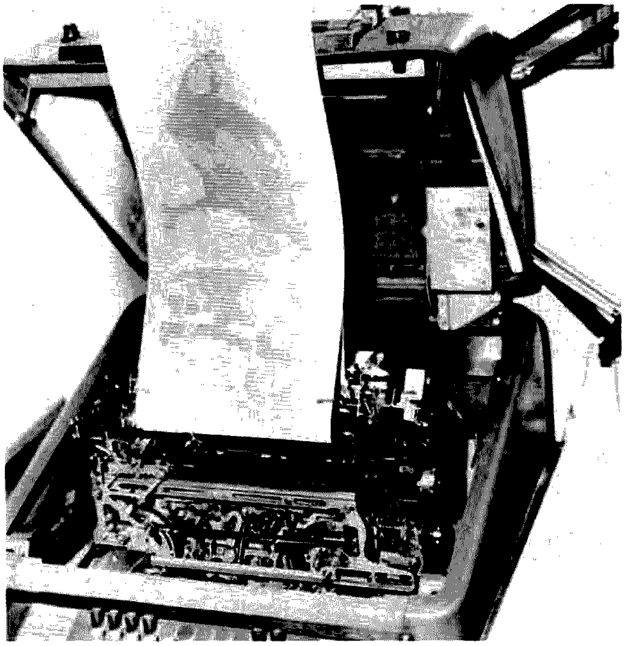
Insert your drawing in the typewriter and type across the top, about six inches down, the numbers 1234567 890 and repeat until you reach 73 numbers. Then do the same down the left-hand side for the length of the sketch. These are reference points for use when you make corrections later and are not copied on the final print. Before you start your print, it is a good idea to make several copies or tracings on additional sheets in case you make too many errors on your first try.

Now insert your sketch into your old nail-buster and start typing right on top of your art work using the letters, numbers, and characters you have selected. Most errors can be erased or typed over. It is best that the ribbon not be too fresh. If an error is too bad, indicate changes with red pencil so you can pick them up later.

When you reach the bot-



A completed picture after RTTY transfer.



Sample copy of a picture as received over the air.

tom, add your title and credit line, transfer the finished work to your machine, and simply type over the copy as your reperf records your pix. You will still make errors, but only a fraction of those that would occur if you typed directly over an original print. You will have to make slight corrections when your print box does not hit the letters directly, adjusting the print accordingly. When I approach more than ½-letter mismatch, I throw up the paper release and gently grasp the paper on either side and make the slight correction by moving the copy. Practice will make these adjustments a quickly solved problem. Do not seek a perfect character match as long as you do not lose a complete space on one line of travel.

It may be more comfortable for you to operate your machine with the cover open for closer viewing of your tape alignment over the typewritten copy. Instead of letting the paper flow over the top of the machine, hang it up over a wire and lightly weight it so you will be able to view the print as a whole as it exits from the rollers.

Here are some suggestions:

- Follow the basic rules of pix-making that are outlined in most contest rules.
- Use no more than 73 characters in one line.
- Use at least ten line feeds at the beginning and end of your picture.
- Use three functions at the beginning of every line. When overlining, use any combination of carriage return, FIGS, or LTRS so as to provide three functions without using line feed.
- Don't forget the guy whose machine does not downshift on space and make sure you add this function or his pix may end up with a lot of 2s where you wanted Ws.

After you have made your tape, print your first playback. Take a red pencil and mark off all the hits and glitches that need correcting. Rerun the tape and correct each error as you are punching your new tape. Unlike the typewritten copy, this time you will have to repunch another tape for any error that you let slip.

If you are going to enter any contests, it is best to make sure you do not have any hidden errors that do not appear in the print, such as unnecessary shift functions or going over a line to add a missing letter. This could cost you points with some judges. You will have to watch for these errors visually as the tape is being run. I have a friend who picks these up on his computer, but this is sneaky.

Finally, when you have all your corrections made, stand back from your print. It will never appear as great as your original typewriter copy, as the outlines of your drawing will no longer appear, but it will develop a character of its own. If at this time you decide that there is either not enough or too much contrast between sections, make another tape and add or subtract characters to these areas.

When you arrive at your final copy and wish to make a print for display, you need not settle for the paper available for teletype machines. Your local art shop has good bond paper in large sheets that you can cut in lengths the same width as your paper roll, providing you have friction feed. Sprocket feed will limit you to sprocket paper. Roll-feed machines have a fine-grade white paper available at stationery supply houses that will produce fine prints for contests and display.

Use a new or re-inked ribbon for final prints. If your reperf produces a chadless-type tape, try to get a chad tape made by a friend for easier storage and mailing. Send your contest print entries in a roller container or neatly rolled in a shoe box to avoid folds. Wrap your prize-winning tape in newspaper to prevent shifting in transit. Of course, you should keep a master copy as there will be no return of your tape or print.

Stop printing everyone else's pix. Make one of your own that will have your call letters on the final line. It is worth the effort. Discover your own little pix tricks. When you create that winner, you can display it on the shack wall with pride. You may even want to copy it on high-contrast line film and make your own unique photographic QSL cards. Let's see your pix on the page soon. ■

Leon Fletcher N6HYK

Monterey CA 93940

How to Increase Your QSOs

N6HYK's seasoned advice will add spice to your CW contacts—even if you aren't a Novice.

Ten students were in the fall, 1981, 10-week course at Pacific Grove Adult School in California, studying to take the tests for licensing as Novices. The instructor, Paul Herrschaft KQ6G, presented excellent instruction—70% of his students passed the FCC test on the first try; the rest passed soon after.

But today, more than a year later, only one of those students is on the air. Why?

There are several reasons, of course. But many Novices tell me there's one big problem that stands out above all others in keeping them off the air: the lack of practical, specific tips on just how to handle CW contacts.

That's no criticism of KQ6G's course, nor, probably, of other typical Novice classes offered around the country. Rather, there is a severe shortage of the specific information every Novice needs immediately after he or she has passed the FCC tests: the tips and techniques about actual on-the-air operation.

But Novices are not the only hams who can benefit from the following details. I've heard many General-class operators, and even a good many Advanceds and Extras, making basic operating goofs, sounding as if it were their first day on a key.

Yet the tips in this article are seldom seen in print or heard from fellow hams. Search, as I have, the standard operating manuals, handouts, instructional guides, and such, and you'll find very little of this kind of information. Mostly all you'll read in the publications and hear from other hams are generalities. "Be patient," reads one. Another suggests, "Be persistent." Such vague words are of little real help.

Here, then, are nitty-gritties about how to search a band, how to increase the number of your QSOs, and how to be a better operator. Here are 11 practical, QSO-tested techniques.

These tips are based on two sources. Most came to me the hard way, from my own on-the-air experiences. But I'm not passing myself off as an expert operator. Rather, I'm a Novice who's disappointed with the limited help available to beginners and aware of the need for experienced hams to be better operators. So, as I began operating my station, I took detailed notes of the problems—and solutions—I met.

That system paid off. It took me just 53 days on the air to contact all states. The last one, Domenico Procida KAØMEI, in McLaughlin, South Dakota, came on the 15-meter band at 1929 UTC, shortly before noon my time, in California, on Tuesday, November 2, 1982. Now, I'm not suggesting that's any kind of record. Rather, I offer such specifics to show you that by using these techniques you can indeed improve your own on-the-air successes.

This is my shack. Here I learned the hard way, through on-the-air experience, the basic tips and techniques presented in this article, not to be found in existing manuals, guides, etc. As I operate, I can glance at stick-on notes posted as reminders: "7,228: Hawaii Storm Net"; WA6IRZ Stan Bringer sked, 3900, 10 pm"; "VE districts needed . . ."

A beginner's collection of QSL cards can grow surprisingly fast. As cards come in, the XYL often gets interested in them.

Referring to my log, I find added pleasure in hamming by pinpointing the location of a station soon after completing a QSO. This one, Jim Wesseling KA9MXO from Spring Grove, Illinois, will have a red dot added to the map to help me keep track of the spread of my QSOs throughout the nation.

The other source for these tips was the 96-member U.S. Naval Postgraduate School Amateur Radio Club in Monterey, California. At one of its monthly meetings, I asked members to tell me specifics they thought would help improve operating skills.

Here's what I learned.

1) *Headphones*: This tip stands out far above all others for two reasons. First, it is absolutely essential. Second, it is rarely mentioned in any of the usual lists of operating tips.

Get yourself a really good set of communication-style headphones. Tell that to the typical ham who's been on the air a month or so and he, or she, may stare at you as if you'd just announced that people need air to breathe. The need, the value, of headphones is apparently so obvious it's almost never mentioned. But there are some rank beginners—I, for one—who need to be told about the need for a headset.

Good phones increase the volume. They focus your attention. They sharpen your listening. They reduce other sounds. They improve, greatly and immediately, your operating. They're indispensable. Absolutely.

How to choose your phones is, frankly, beyond my technical knowledge. I just went to a major dealer of ham equipment and said, "Show me your very best phones." He offered three. I found one felt heavy. Another looked like inferior workmanship. As I picked the third, the salesman said, "That's the set I've found best." My selection: Kenwood HS-5. I have no idea how they measure up with other phones technically. But they fit me, sound great, feel good, and significantly increase my operating skills.

The rest of these tips are not in any order of priority. You should pick out the ones which will help you most at the level of on-the-air operating you're at right now, then make mental notes to use the other tips as the need may arise.

2) *Listen around the "Big Guns."* They're those superpowerful stations. Often they pour out CW at 15 or more words a minute, somehow expecting Novices to answer. Once you hear one of them, tune carefully, slowly, intently, just above and just below their signals. A great many times I've found those powerhouses come on the air and hide, but not completely block, some smaller, less powerful, slower CQer. Often, that modest-sounding station is much more interesting to QSO. He, or she, may often be more eager, receptive, and considerate of your slower, less skilled, less confident operating.

3) *Listen at a "hangout."* That's what I call a spot on the band where stations gather. When 40 meters is open, for example, it's usually at the very lowest end of the band. Then, often, up around say 7.110 to 7.120, there may be a relatively open space, followed by another hangout. If there are but, say, five or so hams operating in those groups, you might be able to catch a CQ quickly and easily. But if ten or more stations are working the hangout, singling one out may be difficult. According to my ears, they just beat each other up, block each other, cut out each other, and interfere with themselves and with potential contacts. They may become a pileup. So I tune elsewhere. I search for another group, but a small, responsible, orderly group. There, often, I can find a good station that is "contactable," if that's a word.

4) *Listen where there's no action.* Chris Thais NQ6Q of Monterey, California, told me, "When I turn my transceiver on, I generally check out the overall sound that's on the air. If I don't hear any traffic, it doesn't necessarily mean the band is down." He sends out a CQ anyway, and, surprisingly often, he says, he gets a contact.

5) *Consider the problems of that old tip, "Send your CQ and your call at the speed you want to copy."* Generally, that's a good technique. But sometimes it may help to send it slower than you can or want to copy. If you're cautious, as I am, you could figure a slower CQ may help make sure someone hears you clearly and correctly.

On the other hand, you'll increase your CW speed if you extend yourself a bit now and then. At least once a day, I give a call to a key that's buzzing along three or so words faster than my present best speed. You, too, should push yourself into copying faster than you feel is comfortable, at least now and then. Sure, you may miss some copy. But you don't have to send "SOLID" after every listen. I find that in a few days of copying somewhat over my speed, I can then move my rate of CQing up a bit and copy most of what comes back with comfort.

6) *When you fumble, slow down!* Don't let yourself fall

into that bad habit you hear often from "Super Fists," those who send over their skills, make fumbles, then speed up still more. Almost always, they just make more and still more errors. You'll be much more successful by slowing down when you can't get your key away from stuttering. Then, after just a half-dozen more words or so, at a slower sending rate, you'll usually get your rhythm back. You'll regain your cool and reduce, sometimes even eliminate, your errors. And then you can start to increase your speed again.

7) *Make your on-the-air time important to you.* One member of the Monterey ham club told me, "Don't try to slip your QSOs in between your other scheduled chores. That will raise your tension level and can leave you with a bitter taste for CW." My experience confirms that advice. Turn on your station and operate your key when you're relaxed, confident, and ready. Consider your time on the air as something special—which, of course, it is.

Still, other hams turn to air-time when they are a bit uptight. They find relaxation in their QSOs. As in all these tips, select what's best for you. Try different tips and techniques. If they work for you, keep them; if they don't interface with your own interests or skills, forget them.

8) *Don't bother with stations which "don't sound right."* Earlier today I was on the air, searching. I heard a faint CQ, so faint I had to struggle to catch the call. "What the heck," I told myself, "give the guy a call—maybe he'll get stronger." Sometimes they do. And, of course, sometimes they get weaker. Then the contact may become frustrating for you. You may get more out of your hamming if you let doubtful calls go by.

Another example of contacts which don't sound right is the ham who fumbles his own call more than once or twice in a CQ. When there's apparently no other signal on the air, I sometimes figure, "Well, maybe he'll settle down once we make contact." Sometimes he does, indeed, become a textbook version of good sending. But often the errors just keep piling up. And I keep getting more and more uncool in trying to read him.

Beginning operators, until they get a fair number of QSOs, often find it hard to think up the words to use and then spell them. To help solve such problems, I refer to a notecard prepared with key phrases on it.

Photos by Steven Ybarrola

9) *Know how to tune up.* This is another elementary technique, yet from what I hear on the air, many hams with years of experience have still to learn how.

I'd read and believed all that literature that says, "Never tune up on the air." But some experienced operators told me, "You have to tune up on the air to make sure your swr is down where it should be." Finally, Tim Wheelis KQ6V, an Extra-class ham living in Pacific Grove, California, came to my shack and showed me just how to do it—*on my equipment*. My problem was that everyone who was telling me what I should do had gear that was different from mine. KQ6V has the same Heathkit equipment as I have. His tips were clear, specific, and relevant. They worked! So you, too, should avoid using tips about gear other than your own.

10) *Check the action on the other bands regularly.* I make it a practice to do that about every hour I'm on the air—after about every two contacts. I might be happy with plenty of contacts on 15 meters, for example, but I want to be there when 10 opens!

11) *Learn to live with QRM and QRN.* A friend of mine, a non-ham, visiting my shack heard the Russian woodpecker. You may not have met that bird yet. It's a loud, harsh, steady, persistent pecking sound. It comes from some Soviet electronics project and is not intentional interference, I'm told. It may last just a few seconds, yet other times it may go on for an hour or longer. Sometimes it settles on just a small part of a band; other times it will range up and down quite an expanse of frequencies. On hearing that horrible sound, my friend asked, "Is he paid by the makers of headache pills?" I doubt that. Still, you should learn to live with it, and with other interferences, static, and distractions. Don't become one of those operators who CWs "I must QRT (stop sending)" as soon as listening gets a bit difficult. Try a bit harder and a bit longer when rough stuff gets on the air, and you'll soon find you can copy through a lot more QRM and QRN than you might have thought.

There, then, are tips and techniques which can help every Novice fill up his or her logs faster than ever. And for you old hands, reviewing such basics just might get you, too, into stations you've never reached before. ■

Novice or experienced: Please send me the tips you've discovered, the techniques you use to improve your on-the-air skills. Include your call, name, and QTH so you might be mentioned in a future article rounding up still more specifics.

Table 1. Apple integrated circuit list.

Lately, many amateurs have been using personal computers in the shack. There have been many fine articles in amateur publications describing some of the uses of home computers as a valuable station accessory.[1,2,3,4,5]

This article will describe a method of obtaining an equivalent to one of the better computers on the market today at a cost well below the normal price. Enough information will be presented to enable you to obtain parts and then build and test a computer using a preassembled board.

System Features

There are many variables that should be considered when selecting a microcomputer system. We can oversimplify a bit and say that the two most important considerations are functionality and price. Or, how can we get the most bang for the buck?

As with other station accessories, we could consider building a computer. There are many articles about how to make a small computer using various microprocessors, but after all the effort of gathering parts, wiring, assembly, and testing, you may be left with a system that has no readily-available software and is without a lot of flexibility.

An easier way is to obtain an assembled board for one of the more popular computers. There are motherboards available for the Apple II computer from legitimate sources.[6,7] Since the entire computer is on a single board, connecting the power supplies, an ASCII keyboard, and a monitor results in an operational system. An ordinary tape recorder can be used to store programs.

Other than the obvious cost savings, there are other advantages to doing it yourself. First, you will have an understanding of what is inside the system should it ever need service. Second, the package can be made more RFI tight than the factory model. All computers generate a certain amount of rf, and when you are trying to pull in a rare DX station out of the mud, each dB of attenuation around your computer (the rf generator) is important. Third, the package can be customized

***Apple is a registered trademark of Apple Computer, Inc.**

to your particular liking. (Three possibilities are rack mounted, table top, or a portable package.) You may even want to leave room for interface circuitry such as a keyer or RTTY. Also, there is the pride and satisfaction of doing it yourself.

Before getting into the actual construction, let's consider some of the advantages/disadvantages of an Apple compared to some of the other personal computers on the market today. The large base of Apples that have been sold means that there is a lot of good software written for it. Application software is available through local users' groups, computer stores, and via mail order from many vendors. The Apple documentation is well written, informative, and easily available. That is important for a project like this.

The graphics capability is very good—at least as good as the other machines in its price class. With the addition of a disk drive and a printer, you could have the makings of a small business system capable of being used for such things as inventory, accounting, tax preparation, and other functions. A word-processing system is one of the most useful applications for a home computer, and you may find yourself waiting in line to update your logs as one of the junior ops finishes a book report. And don't forget the inevitable and captivating video games.

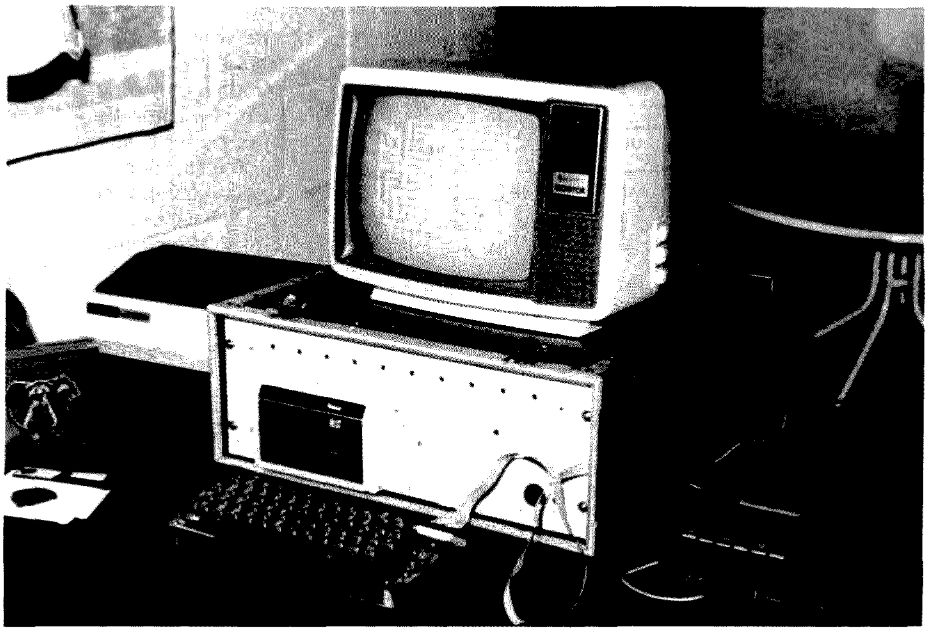

Photo A. Front view of the case with the system in operation. The hole pattern to the right of the disk drive is for the speaker.

Construction

Obviously, the first step in this project is to obtain a motherboard. The boards are available in three different configurations: a bare board, an assembled European version, and an assembled domestic board.[6,7] Assembled and tested boards can usually be obtained for $350 to $450. The bare board typically sells for $100 to $200.

The bare board requires installation of the sockets, I/O (input/output) connectors, discrete circuitry, and, of course, the integrated circuits. The integrated circuits (ICs) required are a 6502 microprocessor, support ICs—mostly 74LS series—and the Apple ROMs (read-only memories) which contain the Basic program and the monitor. Table 1 shows the required integrated circuits.

With the available documentation, assembling a bare board is not much harder than building a kit. (However, I would not recommend the approach for anyone without some experience with digital circuits.) All the IC locations and types are silk-screened on the top of the board, along with the discrete component values. The schematic for the domestic board is in the Apple II *Reference Manual*. This book is highly recommended for all Apple users and is mandatory if building is contemplated. The *Reference Manual* is published by Apple Computer Inc., Cupertino, California (Apple Product #2L0001A).

This book and the Apple ROMs are available from your local Apple dealer (the ROMs must be ordered specially by most dealers). The books and ROMs are available via mail from Applied Invention.[8] Electrovalue[6] also sells the entire integrated circuit package (minus the ROMs) for $60.00 to $75.00 depending on the board configuration. They also have packages that include connectors, the crystal, speaker, etc. Another good source for ROMs and other Apple ICs and manuals is Component Sales.[13] A set of four ROMs (Integer Basic version) can be obtained for $35.00 to $45.00.

The European version of the Apple board can be used without modification except for the high-resolution-graphics mode. This version sells for less than the domestic version and may be easier to find. If you are interested in the hi-res

Photo B. Front of the case with the cover removed. Note the position of the disk drive and the motherboard. The terminal strip on the right is for distribution of the ac power. The copper-clad printed-circuit material can also be seen.

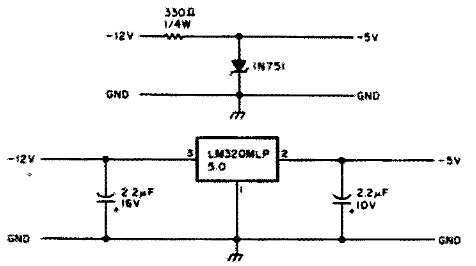

Fig. 1. −5-volt power supply with zener diode (top) or 3-terminal regulator.

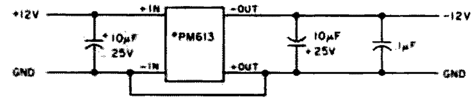

*Fig. 2. Typical circuit for generating −12-volt supply using dc-to-dc converter. (*Available from Power Products, 1400 N.W. 70th St., Fort Lauderdale FL 33309.)*

graphics, modifications can be made. This requires about twenty cuts to the printed circuit board and a similar number of jumpers to be added. Specific instructions for this modification are available from the vendor. (Again, you should have some experience before attempting the modifications.) Without making the modifications, the board is still usable for most applications. Note: If a European board is obtained, test the board for operation in Basic and low-resolution graphics before making the modifications for hi-res.

If you obtain an assembled and tested domestic version, connect the correct power supplies and a monitor and you will be "on line."

Power Supplies

The standard Apple uses a switching power supply. This supply as well as other switching supplies are available from various vendors.[6] Other than the disadvantage of taking more space and some more power, linear supplies are perfectly acceptable. They are more readily available and have less high-frequency noise on the output than the switchers.

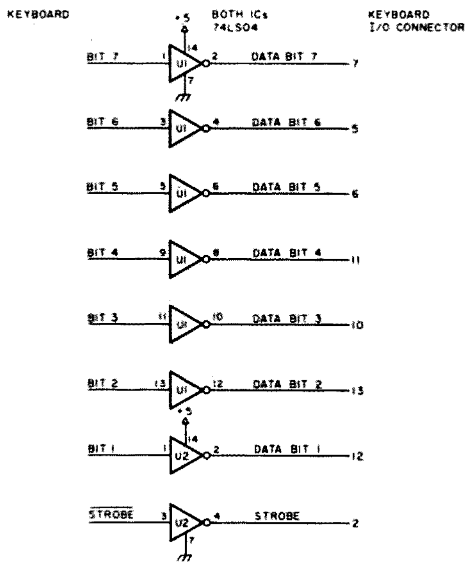

Fig. 3. Inverter circuit schematic.

Table 2 lists the voltages and current requirements for the supplies as well as a typical commercial supply. There have been a lot of articles in this magazine covering the design and fabrication of 12-volt regulated supplies for use with mobile 2-meter equipment, and also articles describing 5-volt logic supplies. Also check your local surplus outlet; I was fortunate enough to find suitable 12- and 5-volt supplies.

Another good source of reasonably-priced supplies is Jameco Electronics, 1355 Shoreway Rd., Belmont, California 94002; (415)-592-8097.

If you are contemplating adding expansion boards and other circuitry, consider using supplies with extra current capability. A word of caution: Linear supplies with more current capability can be used, but beware of multiple-output switching supplies with more capacity than needed. Some models require a certain minimum load on one or more outputs to operate correctly.

The power supplies get connected to the motherboard using a six-pin connector. The connector is an Amp #9-35028-1. The connector is available from Electrovalue or can be ordered specially by your local Apple dealer. If you can't wait for the Amp connector, solder six wires to the back of the board and put another connector between the supplies and the board. I used a Cinch six-prong connector pair. The connector coming from the board should be the male. The connector is wired as follows:

Pin	Function
1	GND
2	GND
3	+5 V
4	+12 V
5	−12 V
6	−5 V

Since the −5-volt supply requires very little current, it can be generated from the −12-volt supply using either a zener diode or a three-terminal regulator as shown in Figs. 1(a) and 1(b).

The −12-volt supply can be obtained with a line-operated regulator, but low-current supplies are not as common as the higher current models. Look for dual-output +5- and −12-volt units. Another alternative is to generate the −12 from the +12 or +5 volts using a dc-to-dc converter. A schematic for a typical circuit is shown in Fig. 2. The device specified is capable of supplying 80 mA, so caution should be used if the system is expanded using function cards.

Several alternative methods have been presented to obtain the necessary power; the choice depends essentially on what is available or can be obtained easily.

Keyboard

Almost any ASCII (American Standard Code for Information Interchange)-encoded keyboard can be used. Keyboards can be obtained from several supply houses.[6] The keyboard must be wired into a sixteen-pin DIP connector. The pinout is shown in Table 3.

Some older keyboards have inverted outputs. The Apple board looks for a high output when the data is true. For example, when the B key is pressed, the output should be 1000011—where a zero (0) is ground and a one (1) is 3 to 5 volts. If necessary, two hex inverter chips can be used to convert a negative-output keyboard into an Apple-compatible unit. A schematic for an inverter circuit is shown in Fig. 3.

Monitor

Some type of video display is necessary to interface with the Apple. There are several alternatives. A surplus monitor would cost some $25.00 to $100. A

black and white TV could run from no cost to $90.00. A new monitor is around $100 to $150. A portable color TV will cost $100 to $400. A color monitor runs from $300 to $500.

Monitors can be found on the surplus market. Most of these will be black and white. Any monitor compatible with the Electronic Industries Association (EIA) and National Television Standards Committee (NTSC) standard will work. A one-volt (adjustable) composite color video signal is available at the rear of the board. This signal can be fed to the monitor via a cable, usually with two RCA-type jacks.

The new monitors on the market today are usually green on black and are much easier on the eyes than the black-and-white versions. The graphics displays also are much more vivid. These can be obtained from most computer supply outlets.[9]

A regular television set is suitable for use as a monitor. Since the Apple can generate color graphics, many users prefer a color TV. The display on a TV is not as sharp and crisp as a monitor. Of course, with a TV you can disconnect the computer and watch Mork and Mindy or Laverne and Shirley. (Note: Some may consider that feature a disadvantage.)

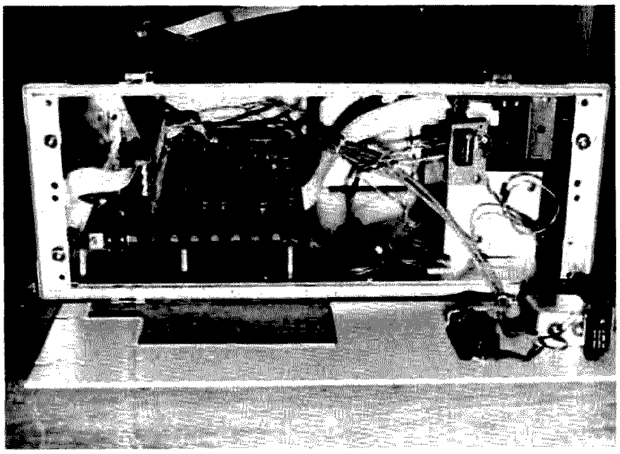

Photo C. The case with the rear panel removed. The motherboard is on the left, and the expansion connectors for peripheral cards can be seen. The power supplies are on the right; the supply mounted to the bottom is +12 V at 1.5 A, and the supply mounted above and to the upper right of the case is the +5-volt supply. The dc-to-dc converter circuit for the −12 is shown mounted to the case of the +12 supply. The components on the right are a line filter, circuit breaker, and an ac line outlet.

An rf modulator must be used between the computer output and the TV. The composite video signal modulates the output of the modulator in one of the two lower VHF television bands: 61.25 MHz (channel 3) or 67.25 MHz (channel 4). Modulators are available from your local computer dealer or Radio Shack (part #277-221).

The best monitor, and naturally the most expensive, is a color monitor designed for computer use. The display is clear and sharp like the monochrome monitors and the colors are vivid. The resulting color graphics are superior to those produced on a color TV.

Choosing the monitor is mostly a matter of taste and the thickness of one's wallet. It is easiest to start with a system using any available TV and then upgrade at a later date.

System Test

Before putting the system in a package, it is best to test it on a bench. Assuming an assembled motherboard is available, connect the power supplies as described earlier. Double-check the wiring before turning on the supplies. Connect a known good monitor or TV as described. Note that we do not connect the keyboard yet.

Now for the first test. Turn on the power to the TV or monitor, and then the system supplies. The screen should be filled with a bunch of random characters, letters, numbers, question marks, anything. This is the random turn-on pattern of what is in the screen-display memory. At the bottom left of the screen should be an asterisk. If all is well, skip the next three paragraphs.

If the screen does not show random characters, turn off the power supplies and check the connections and output voltages again. If everything is OK, turn on the power to the board. Check the power to the board by measuring the voltages on the board with respect to power ground. Check for obvious faults such as bent IC pins, shorts, loose components, etc. If there are no mechanical problems and the power is correct, make sure that your monitor or modulator and TV and connecting cables are operational by hooking them up to a friend's computer. (It is not necessary to use an Apple; several other systems use a video output.)

Voltage	Apple Supply Capability	Actual Current Required (System 1)	Actual Current Required (System 2)	Recommended Supply
+5V	2.5 Amp	1.5 Amp	1.8 Amp	Power/Mate EM-5B or equiv. 5 V at 3 A
−5V	250 mA	10 mA	12 mA	See text
+12V	1.5 Amp	400 mA	1.2 Amp	Power/Mate EM-12B or equiv. 12 V at 1.5 A
−12V	250 mA	15 mA	80 mA	Power/Mate MM-12A or equiv. 12 V at 100 mA

Notes: (1) System 1—48K Apple with no peripherals.
(2) System 2—64K Apple with disk drive and controller, printer interface, and a 16K RAM card.
(3) Power/Mate Corp., 514 S. River St., Hackensack NJ 07601; (201)-440-3100. Will sell small orders.

Table 2. Voltage and current requirements.

Pin	Function	Notes
1	+5 V	Power supply to keyboard (120 mA max)
2	Strobe	From keyboard, 10 microsec min
3	Reset	From keyboard, shorted to GND when reset
4	No connection	
5	Data 5	Part of seven-bit ASCII output
6	Data 4	Ditto
7	Data 6	Ditto
8	Ground	System electrical ground (GND)
9	No connection	
10	Data 2	ASCII output
11	Data 3	Ditto
12	Data 0	Ditto
14	No connection	
15	−12 V	Power supply to keyboard
16	No connection	

Table 3. Keyboard connector pinout.

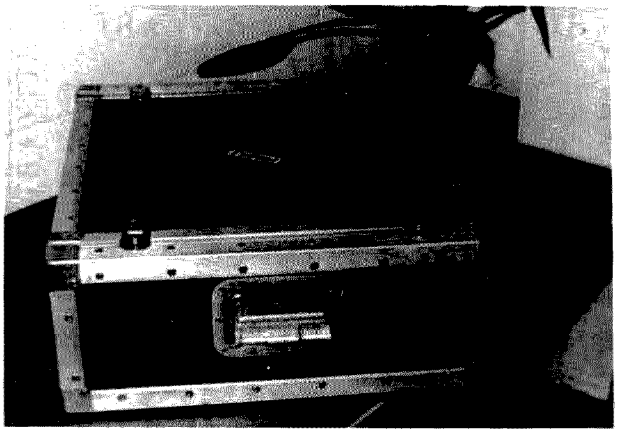

Photo D. This photograph shows the case buttoned up, ready for travel.

Photo E. The benchtop wooden "enclosure" described in the text.

If the problem still persists after the above tests, suspect a bad IC. The solution to this problem is substitution. You will need either a known good Apple from which you can substitute ICs one at a time or an extra set of components. Another troubleshooting step is to put the board into a known good Apple and try it out.

To narrow down the possible IC faults to some degree, try the following substitutions. If nothing appears on the screen, something is wrong with the clock-divider chain. Check B1, B2, C1, C2, and D11 through D14. Also check the video-generator section, A3, A5, A8, A9, A10, B4, B8, B9, and B10. If the screen is covered by a block pattern which changes in a random fashion each time power is turned on, a data line or memory chip is probably bad. Check the first memory bank, C3 through C10, and the memory data latches, B5 and B8. Check the RAM address multiplexer, C12, E11, E12, E13, and E14. Verify that the RAM select chips, C1, C12, E2, F2, and J1, are operational.

If the monitor comes up with a random character pattern, it indicates that the CPU is working, the clock gets divided down correctly, the address and data lines work, and so on. Turn the power off and connect the keyboard. Turn the power on and in response to the asterisk prompt, type a Control B. The unit will come up in Basic. If the ROM contains Integer Basic, a > sign will appear. For units with floating-point Applesoft Basic, a] prompt will appear. Once this happens, you probably have a working system. Write a small test program to further verify operation.

There are several books on Basic. The Apple II *User's Guide*[11] is an excellent reference which also covers other topics of interest such as differences between the two Apple Basics, hardware interface, etc.

To store programs for later use, some type of magnetic storage medium is required. An ordinary cassette tape recorder can be used for program storage and also can serve as a way of using commercially-available software. The Apple II *Reference Manual* describes the interface and operation.

The first peripheral to consider should be a disk drive. After working with cassettes, the convenience of a disk drive will be appreciated. Disk drives and controllers are available from several sources including Applied Invention.[8]

Packaging

As we briefly discussed earlier, there are several different ways in which a unit such as this could be packaged. I was fortunate enough to obtain at a reasonable price the case shown in the photographs. The case is open only at the back and front so that access to the board and power supplies is limited, but it is sturdy and portable. Snapping on the front and rear covers completely closes the case and provides a carrying handle.

A few trips to the local surplus outlets might turn up a similar bargain. Unlike most Apple installations, I chose to have the disk built in rather than sitting on top of the box. Using a hacksaw, I cut an opening in the front

panel for the front of the drive as shown in Photo A. The drive is screwed to the bottom of the case.

Since the case is not metal, I also took the extra precaution of covering the entire inside with double-sided copper-clad PC-board material. All the separate sheets of material are electrically tied together using solder and ground braid. This proved to be a considerable help in curing the TV interference caused by the system.

If the unit is going to stay in one location, consider the approach taken by Jules Madey K2KGJ. Photo E shows this packaging scheme. The motherboard sits on the bench and is covered by an inverted U-shaped wood structure. The wood cover supports the monitor, disk drives and various interface circuitry. The power supplies are mounted below the bench and connected via a cable. The keyboard is mounted in another wood box in front of the system. Everything in the system is very accessible, and the packaging can easily be finished in one evening. This method could also serve as an interim package until a suitable case could be located.

Some manufacturers have cases available with sloping fronts. With the larger models, the motherboard and power supplies could be mounted on the bottom and the keyboard fastened to the sloping front through an appropriate cutout. The keyboard would then be at the correct angle for typing. This package would be very similar to a factory-built Apple. Two companies that make that type of enclosure are Buckeye Stamping Co.[11] and Hammond Manufacturing.[12] (Ask for the "Desk Top Consoles" catalog from Hammond.)

Suitable cases and enclosures show up at hamfests and surplus houses, so keep your eyes open.

Conclusion

This article presented some ideas, thoughts, and actual hardware implementations of home-built computers. The techniques used by most of the manufacturers is to put everything on one board. These boards are sold also to OEM manufacturers for use in computer-based products. This makes full-function computers available if one does a little digging. Most of what was discussed here can be applied to computers other than the Apple. I hope this article inspires some other home-built computers. ■

PROJECT PACKS

BASED ON THE BRITISH PUBLICATION—RADIO & ELECTRONICS WORLD

SYNTHESIZED AIRBAND RECEIVER

720 Channels (thumb-wheel switches)
118 MHz to 136 MHz
25 KHz channels
Built in AC Power Supply
Provision for 12v battery use-low drain
CMOS Motorola Synthesizer Chip
Good dynamic range

Kit includes PCBoard, all components and hardware (enclosure and speaker not included).

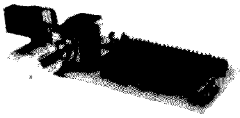
Stock No. 40-72001 — $162.50*

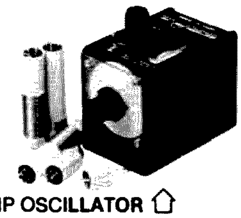
AIRBAND MEMORY

Memory add-on for synthesized airband receiver.
160 Memory channels with battery data retention.
LED Channel readout

Kit includes PCB, all components, NiCad battery, and rotary code switch.

Stock No. 41-00303 — $49.95*





FET DIP OSCILLATOR

(a must for the serious RF experimenter)

Checks resonant frequency of tuned circuits. A signal source for adjusting circuits. Marker generator companion for a sweep generator. An absorption wave meter.

Specifications:
1.6-215 MHz
5 ranges
self-contained, 9v battery
Meter and audio (piezo buzzer) dip indication

Kit includes PCBoard, all components and hardware punched, painted and lettered case.

Stock No. 40-16215 — $52.50*

R + EW U.S. Agent

RADIOKIT

Box 411S, Greenville, NH 03048

(603) 878-1033 ✓69

*Shipping and Handling $2.50

UHF TO VHF CONVERTER

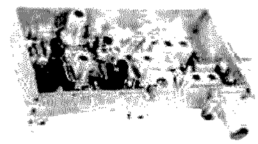
(dual purpose converter for 70cm to 2M and 70 cm to UHF TV band)

Specifications:
Freq. Coverage 8MHz in the band 430-440 MHz with 144-148 MHz IF.
RF Gain 8dB (single filter model)
Noise Figure 2.5dB (single filter model)

AMATEUR TELEVISION
Freq. Coverage 434-440 MHz
IF Frequency 726-732 MHz
RF Gain 5dB (single filter model)

GENERAL
Supply Voltage 10V stabilized
Supply Current 30 ma approx.

Complete kit of parts including PCB, components, xtals and enclosure



Stock No.	Input Freq MHz	IF Output (MHz) Commo	IF Output (MHz) ATV	Xtal Freq MHz
------------	432-438	144-148	722-728	96.0000 △
40-00170	434 438	144-148	724-730	96.6887

40-00370	438-440	144-148	728-734	98.0000 +

△ Supplied with all kits
+ Recommended for ATV — $60.50 each

FCC

In a flurry of activity, the FCC recently made several modifications in the amateur regulations. The change which has most likely affected amateur habits is the deletion of all logging requirements in Part 97. As of June 9, no transmissions had to be logged, unless specifically requested by the Commission. Third-party traffic is also exempt from any logging requirements.

The FCC also engaged in some housecleaning in an effort to clear up ambiguous regulations and delete outdated rules. Among those deletions was the requirement of a CW ID for amateurs using video and some common digital codes.

Finally, in an NPRM, the Commission proposed an expansion of the 10-meter repeater subband, citing the recent rapid growth in this area.

Here are the final orders and the NPRM as they appeared in the Federal Register:

Appendix

Parts 0 and 97 of Chapter I of Title 47 of the Code of Federal Regulations are amended as follows:

PART 0—COMMISSION ORGANIZATION

A.1. Section 0.314 is amended by adding new paragraph (x) as follows:

§ 0.314 Additional authority delegated.

* * * * *

(x) When deemed necessary by the Engineer-in-Charge of a Commission field facility to assure compliance with the Rules, a station licensee shall maintain a record of such operating and maintenance records as may be necessary to resolve conditions of interference or deficient technical operation.

PART 97—AMATEUR RADIO SERVICE

B.1. In § 97.79, paragraph (b) is revised to read as follows:

§ 97.79 Control operator requirements.

* * * * *

(b) Every amateur radio station, when in operation, shall have a control operator. The control operator shall be present at a control point of the station, except when the station is operated under automatic control. (Automatic control is only permitted where specifically authorized by the rules of this part.) The control operator may be the station licensee, if a licensed amateur radio operator, or may be another amateur radio operator with the required class of license and designated by the station licensee. The control operator shall also be responsible, together with the station licensee, for the proper operation of the station. (For purposes of enforcement of the rules of this part, the FCC will presume that the station licensee is, at all times, the control operator of the station, unless documentation exists to the contrary.)

* * * * *

2. In § 97.85, a new paragraph (g) is added to read as follows:

§ 97.85 Repeater operation.

* * * * *

(g) Each station in repeater operation transmitting with an effective radiated power greater than 100 watts on frequencies between 29.5 and 420 MHz, or 400 watts on frequencies between 420 and 1215 MHz, shall have the following information included in the station records during any period of operation:

(1) The location of the station transmitting antenna marked upon a topographic map having contour intervals and having a scale of 1:250,000 (indexes and ordering information for suitable maps are available from the U.S. Geological Survey, Washington, D.C. 20242, or from the Federal Center, Denver, CO 80255);

(2) The transmitting antenna height above average terrain (see Appendix 5);

(3) The effective radiated power in the horizontal plane for the main lobe of antenna pattern, calculated for the maximum transmitter output power which occurs during operation;

(4) The maximum output power which occurs during operations;

(5) The loss in the transmission line between the transmitter and the antenna (including devices such as duplexers, cavities or circulators), expressed in decibels; and

(6) The relative gain in the horizontal plane of the transmitting antenna.

3. In § 97.88, paparagraph (a) is revised, and new paragraphs (f) and (g) are added to read as follows:

§ 97.88 Operation of a station by remote control.

* * * * *

(a) A photocopy of the license for the remotely controlled station shall be posted in a conspicuous place at the station location.

* * * * *

(f) The station records shall include during any period of operation:

(1) The names, addresses, and call signs of all persons authorized by the station licensee to be control operators; and

(2) A functional block diagram of the control link and a technical explanation sufficient to describe its operation.

(g) Each remotely controlled station shall be protected against unauthorized station operation, whether caused by activation of the control link, or otherwise.

4. Section 97.90 is added to read as follows:

§ 97.90 System network diagram required.

When a station has one or more associated stations, that is, stations in repeater or auxiliary operation, a system network diagram (see § 97.3(v)) shall be included in the station records during any period of operation.

5. Section 97.92 is added to read as follows:

§ 97.92 Record of operations.

When deemed necessary by the Engineer-in-Charge (EIC) of a Commission field facility to assure compliance with the rules of this part, a station licensee shall maintain a record of station operations containing such items of information as the EIC may require under Section 0.314(x).

§ 97.99 [Amended]

6. In § 97.99, paragraph (c) is removed.

§ 97.103 Undesignated heading. [Removed]

7. Section 97.103 and the undesignated heading "Logs" which precedes § 97.103 are removed in their entirety.

§ 97.105 [Removed]

8. Section 97.105 is removed.

§ 97.417 [Amended]

9. In § 97.417, paparagraph (d) is removed.

PART 97—[AMENDED]

Part 97 of the Commission's Rules and Regulations, 47 CFR Part 97, is amended as follows:

1. In § 97.13, paragraphs (c) and (d) are revised to read as follows:

§ 97.13 Renewal or modification of operator license.

* * * * *

(c) Application for renewal and/or modification of an amateur operator license shall be submitted on FCC Form 610 and shall be accompanied by the applicant's license or a photocopy thereof. Application for renewal of unexpired licenses must be made during the license term and should be filed within 90 days, but not later than 30 days, prior to the end of the license term. In any case in which the licensee has, in accordance with the provisions of this chapter, made timely and sufficient application for renewal of an unexpired license, no license with reference to any activity of a continuing nature shall expire until such application shall have been finally determined.

(d) If a license is allowed to expire, application for renewal may be made during a period of grace of five years after the expiration date. During this five-year period of grace, an expired license is not valid. A license renewed during the grace period will be dated currently and will not be backdated to the date of its expiration. Application for renewal shall be submitted on FCC Form 610 and shall be accompanied by the applicant's license or a photocopy thereof.

§ 97.32 [Amended]

2. In § 97.32, paragraph (f) is removed in its entirety.

§ 97.61 [Amended]

3. In § 97.61, the parenthetical phrase in paragraph (e) is revised to read as follows:

* * * * *

(e) * * *
(when type F1 or A2J emissions are employed in these bands, the radio or audio frequency shift, as appropriate, shall not exceed 1000 Hz)

4. In § 97.69, paragraph (a)(3) is removed in its entirety and paragraphs (a)(2) and (b)(3) are revised to read as follows:

§ 97.69 Digital communications.

* * * * *

(a) * * *

(2) When type A2, F1 or F2 emissions are used on frequencies below 50 MHz, the radio or audio frequency shift (the difference between the frequency for the "mark" signal and that for the "space" signal), as appropriate, shall not exceed 1000 Hz. When these emissions are used on frequencies above 50 MHz, the frequency shift, in hertz, shall not exceed the sending speed, in baud, of the transmission, or 1000 Hz, whichever is greater.

(b) * * *

(3) The International Radio Consultative Committee (CCIR) Recommendations 476-2 and 476-3 (commonly known as AMTOR):

provided that the code, baud rate and emission timing shall conform to the specifications of CCIR 476-2 (1978) or CCIR 476-3 (1982), Mode A or Mode B.

* * * * *

5. Section 97.81 is revised to read as follows:

§ 97.81 Authorized apparatus.

(a) An amateur station license authorizes the use, under control of the licensee, of all transmitting apparatus at the fixed location specified in the station license which is operated on any frequency or frequencies allocated to the Amateur Radio Service, and, in addition, authorizes the use, under control of the licensee, of portable and mobile transmitting apparatus operated at other locations.

(b) The apparatus authorized for use by paragraph (a) of this section shall be available for inspection upon request by an authorized Commission representative.

6. In § 97.84, paragraph (g) is revised to read as follows:

§ 97.84 Station identification.

* * * * *

(g) The identification required by this section shall be given on each frequency being utilized for transmission and shall be made in one of the following manners:

(1) By telegraphy using the international Morse code (if this identification is made by an automatic device used only for identification, the code speed shall not exceed 20 words per minute);

(2) By telephony using the English language (the Commission encourages the use of a nationally or internationally recognized standard phonetic alphabet as an aid for correct telephone identification);

(3) By telegraphy using any code authorized by § 97.69(b), when the particular code is used for transmission of all or part of the communication or when the communication is transmitted in any digital code on frequencies above 50 MHz; or

(4) By video using readily legible characters when A5 emissions are used, the monochrome portions of which conform, at a minimum, to the monochrome transmission standards of § 73.682(a)(6) through § 73.682(a)(13), inclusive (with the exception of § 73.682(a)(9)(iii) and § 73.682(a)(9)(iv)).

* * * * *

7. In § 97.99, the introductory paragraph is revised to read as follows:

§ 97.99 Stations used only for radio control of remote model crafts and vehicles.

An amateur radio station in radio control operation with a mean output power not exceeding one watt may, when used for the control of a remote model craft or vehicle, be operated under the special provisions of this section, provided that a writing indicating the station call sign and the licensee's name and address is affixed to the transmitter.

* * * * *

8. In § 97.173, paragraph (d) is revised to read as follows:

§ 97.173 Application for RACES station license.

* * * * *

(d) If the application is for a RACES station to be in any special manner covered by § 97.42, those showings specified for non-RACES stations shall also be submitted.

PART 97—[AMENDED]

It is proposed that Part 97 of the Commission's Rules, 47 CFR Part 97, be amended as follows:

Section 97.61 paragraph (c) would be revised to read as follows:

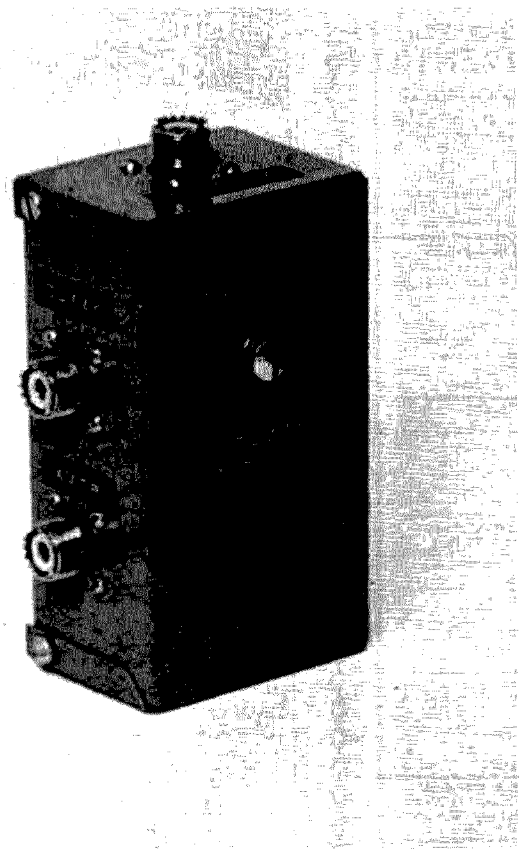
§ 97.61 Authorized frequencies and emissions.

* * * * *

(c) All amateur frequency bands above 29.0 MHz are available for repeater operation, except 50.0–52.0 MHz, 144.0–144.5 MHz, 145.5–146.0MHz, 220.0–220.5MHz, 431.0–433.0MHz, and 435.0–438.0MHz. Both the input (receiving) and output (Transmitting) frequencies of a station in repeater operation shall be frequencies available for repeater operation.

Build This Super Switch

The only thing this switch won't do is brew your coffee. It's the lazy man's delight.



The lazy man's switch box.

R. K. Forsyth K4YS
1012 West Street
Rockledge FL 32955

Although I've often heard that necessity is the mother of invention, I believe that in my case it was just pure laziness. And that is why I designed and built the switch box to be described. It does all of the following things with just one flip of a switch:

- Connects your transmitter to your dummy load for initial tune-up.
- Connects your transmitter through your antenna-matching unit to your antenna for final tune-up and transmit.
- Disconnects the center lead of your antenna coax from your equipment and grounds it to your coax shielding when you are finished transmitting.
- Provides a simple, visual rf power-output monitor from your transmitter.

The switch box did not just develop at one time but came about as the result of an analysis of problems common to most amateurs.

Although many amateurs have dummy loads, often they are not used because disconnecting your coax cables from your tuning unit and connecting your dummy load for an initial tune-up takes time and is inconvenient. But there are some real advantages in first tuning up into your dummy load that should be considered in more detail.

First, you eliminate unnecessary QRM, which is important in our already overcrowded bands. And there is another technical advantage. By tuning up your transmitter into your dummy load initially, you are assured that your swr is 1:1, which prevents the possibility of excessive rf currents or voltages damaging your equipment. After you are properly tuned up into your dummy load, you should

not do any further adjusting of your transmitter rf controls. Then when you switch over into your antenna system, you have only to adjust your antenna-matching network. And by either remembering approximately where the dial settings of your tuning unit are for the various frequencies or using a simple chart or graph to set the dials, you can again keep your swr down to a reasonably low level until you fine-tune the controls for an swr of 1:1.

This technique, which actually is only good engineering practice, reduces your tune-up time and protects your rig as much as possible from dangerous tune-up conditions. Attempting to tune up your equipment without first going through the dummy load step just outlined means that you are trying to adjust both your transmitter and tuning-unit dials at the same time. This can lead to dangerous impedance mismatch conditions until your swr reaches its final lowest value. This haphazard procedure is not to be recommended if you value your equipment.

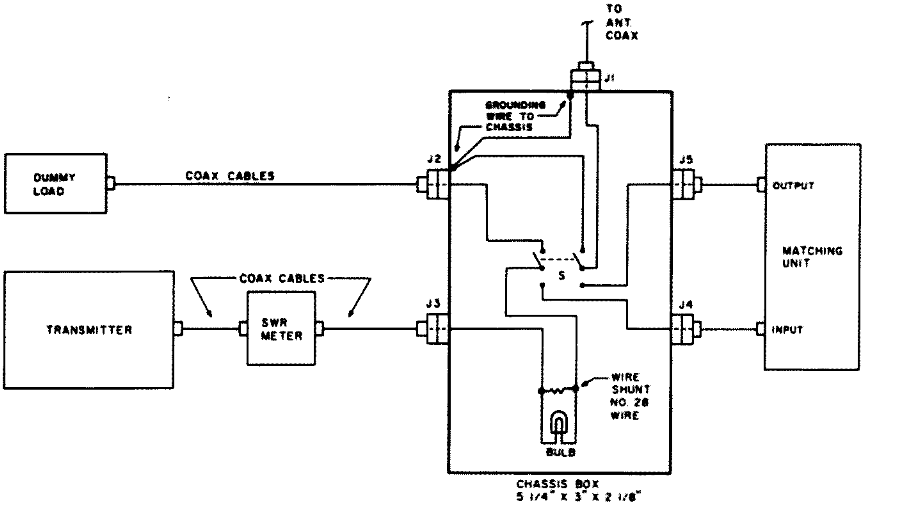


Fig. 1. Schematic diagram. J1-J5—SO-239 coax jack. S—275-652, 6-A DPDT switch. Bulb—PR2, 2.38 V, 500 mA. Mounting hardware—20 #4-40 ½-inch round-head machine screws and nuts. Grommet—bag of assorted sizes. All parts from Radio Shack.

The provision of disconnecting the center lead of your antenna coax from your equipment and grounding it to the coax shield when your station is shut down is a common-sense precaution that will drain off any static voltage buildup and eliminate any effects of induced voltages from a nearby lightning strike. In my own case, I had a diode in my swr meter burn out a couple of years ago when my antenna was not grounded and lightning hit nearby. That one experience made a believer out of me, and now I never leave my shack without first making sure that my equipment is disconnected from the antenna circuit.

It should definitely be pointed out, however, that just disconnecting the center of your antenna coax and grounding it to the shield is not a lightning-protection device! When lightning hits your antenna system directly, it can easily travel down the shield and, because of the extremely high voltages and currents involved, cause all sorts of damage. In a heavy lightning storm it is best to completely disconnect all incoming antenna leads to your shack and ground your antenna outside directly through a really heavy cable to a good ground. At least that is the procedure I've been using here, particularly since Florida has more lightning storms than any other state in the Union.

The rf-monitor circuit is nothing more than a simple small incandescent bulb shunted down with about three inches of number 28 wire in series with the rf output of the transmitter. The size of the bulb and the shunting wires are dependent, naturally, upon the power you run. In my case, a PR2 lamp from Radio Shack rated at 2.38 volts, 500 mA, worked just fine with my Ten-Tec Omni D. The friendly blinking light makes it fun to operate in a partly darkened room, as I often do in the evenings. And it is always reassuring to have a continuous monitor to tell you that everything is working as it should. As shown in the photograph, the bulb is just pushed into a rubber grommet, which makes for a good, neat, and insulated mounting.

Actually, the basic idea is as old as ham radio and makes me remember many years ago when a single turn of the wire soldered to a flashlight bulb was one of my most valuable tools. It was useful in neutralizing, tuning up the transmitter, and checking output when placed near the antenna coupler.

As seen in the diagram, the circuit is simple and the wiring is straightforward. The layout is not critical, and the project is simple enough to be, perhaps, an amateur's first attempt in getting acquainted with the fun of building his own gear.

After all the holes were drilled, a coat of gray enamel was used to paint the outside of the box. It was dried overnight and then baked in the oven at 250° F for fifteen minutes to provide a hard, good-looking finish. The decals added the final touch and ensured that I got my cables hooked properly.

Because the chassis box is of split construction, a wire was connected from J1 to J2 inside of the box so as not to have to rely upon the chassis contact for an rf path. Although a six-Ampere switch was used, I did try the unit at a friend's station with a linear amplifier, and the unit worked fine without the switch heating or any arc-over. However, ten-Ampere switches are commercially available for amateurs who may be running a California kilowatt. All other parts were obtained from Radio Shack, which simplified procurement problems.

Tests showed that, as expected, insertion of the unit changed the original settings of the antenna-matching unit slightly. (This generally happens whenever you change the configuration of your coax cables, probably because of such things as induced currents in coax shields or other minor secondary effects.) As in all rf projects, keep all cables and connections as short as practical and be sure that your coax jacks are well grounded to the chassis.

The real value to me has been the ease with which I can now tune up first into my dummy load and then, with a flip of the switch, into my tuning unit and antenna. It sure is a lazy man's switch box! ■

The Amazing Cylindrabola

This microwave antenna is easier to build than a dish. But it works just as well.

When you mention microwave antennas to most amateurs, the image that comes to mind is a large circular dish antenna. I have nothing against this type of antenna and use it at work and at home. However, I feel that many amateurs are turned away from microwave frequencies when they see the constructional difficulty of building a three-dimensional parabolic surface.

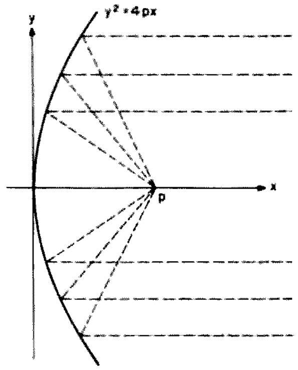

Fig. 1. Parabolic curve.

When maximum gain is needed, the full parabola is necessary, but there are times when it is not. After all, most amateurs just starting out on the high frequency bands do not initially erect rhombics. In recent months, I have been asked to build antennas for monitoring a studio microwave link for a local television station and for intercepting synchronization pulses from a radar site. In each case, the requirements were for moderate beamwidth, medium gain, and low cost. The last requirement was the primary goal. Each request was solved with the same antenna—a cylindrical parabola.

The cylindrical parabola is easily fabricated by hand with sheet metal formed in only one plane. The prototype unit described here was tested initially with an MDS receiver. The MDS signal offers several benefits to antenna work. First, the wavelength (14 cm) is short enough to permit reasonable-size antenna dimensions. Second, the signal is far enough away (3 miles from my location) to approximate a far field source. Third, the signal is available 24 hours a day—they maintain it, not I. And fourth, the bandwidth is large—6 MHz.

The major shortcoming of a cylindrical parabola is the unequal E- and H-plane beamwidths. The beamwidth is smallest in the plane of the curve. The smaller beamwidth is the same as for a dish antenna of the same diameter, while the larger beamwidth is essentially the beamwidth of the feed.

The antenna consists of two parts: the reflector and the feed. Both of the tasks referred to above were handled with the same reflector but with a difference in the size and type of feed. The studio-link

y	x

± 8"	3.20"
± 9"	4.05"
± 10"	5.00"
± 11"	6.05"

Table 1. X and y values used to make 22-inch-wide, 5-inch focal length cylindrical parabola antenna.

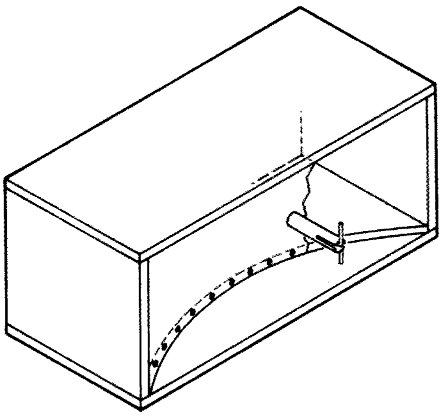

Fig. 2. Box construction with cutaway view of the lower surface support rib.

monitor used a slotted dipole like the one to be described. The radar monitor used a waveguide-to-coax transition as a feed.

The equation for the shape of a cylindrical parabola is identical to that for a circular parabola: $y^2 = 4px$, where y = distance measured tangent to the vertex, x = distance measured perpendicular to the vertex, and p = focal length of the antenna.

Fig. 1 is a graph of a parabola. The table gives the x and y coordinates of the curve used for the antenna shown in the photo. It has a focal length of five inches and a width of 22 inches. The height of the surface is one foot—just over two wavelengths. Increasing the height has little effect on the gain due to the rapid falloff of the radiation pattern of the dipole feed. The same effect is noted with corner reflector antennas.

A thin aluminum sheet was used for the reflector surface because I had some aluminum flashing left over from a home-improvement job. Hardware cloth or coarse wire screen could also have been used; as long as the largest opening is less than one-tenth wavelength, no degradation will be noticed. The aluminum sheet was fastened to the ribs with number 7 sheet-metal screws spaced 2 inches apart. (If wire screen were used, it could be stapled in place.)

The metal sheet was spray-painted flat white before final installation. The paint improves the antenna appearance but more importantly it serves as a fire preventative. The natural aluminum surface forms a good reflector for visible and infrared solar radiation. The intensity at the focus is sufficient to ignite a small stick in seconds.

The parabolic shape is maintained by two ribs made from half-inch plywood. The curve was laid out on graph paper, plotting the curve for y=0 to y=11. The curve was transferred to the plywood by tracing over the curve with carbon paper placed between the graph paper and the plywood. The graph then was flipped over and the other portion of the curve traced out. The two ribs were clamped together and cut simultaneously on a bandsaw. (No, I do not have a bandsaw. I use one at the Naval Air Station hobby shop, a benefit of being a weekend warrior.) The overall construction is shown in Fig. 2 and in the photograph.

The slotted dipole feed is similar in design to the one described in my article on a short backfire antenna published in the October, 1982, issue of *73*.

I do not have facilities for determining antenna gain directly, but I can make gain comparisons by placing an attenuator between the MDS converter and the receiver and noting how much attenuation must be added or subtracted to maintain a constant signal level when different antennas are connected. The completed antenna displays a gain of 10 to 11 dB over the popular coffee-can horn antenna. By simple aperture ratioing, the expected gain is 11 dB; the full height is not illuminated, however, so the 10-11-dB measurement is reasonable. ■

Colorful RTTY: An Advanced System for the TRS-80C

It's all here—a TU, program, and modem to turn your CoCo into a professional-quality RTTY terminal.

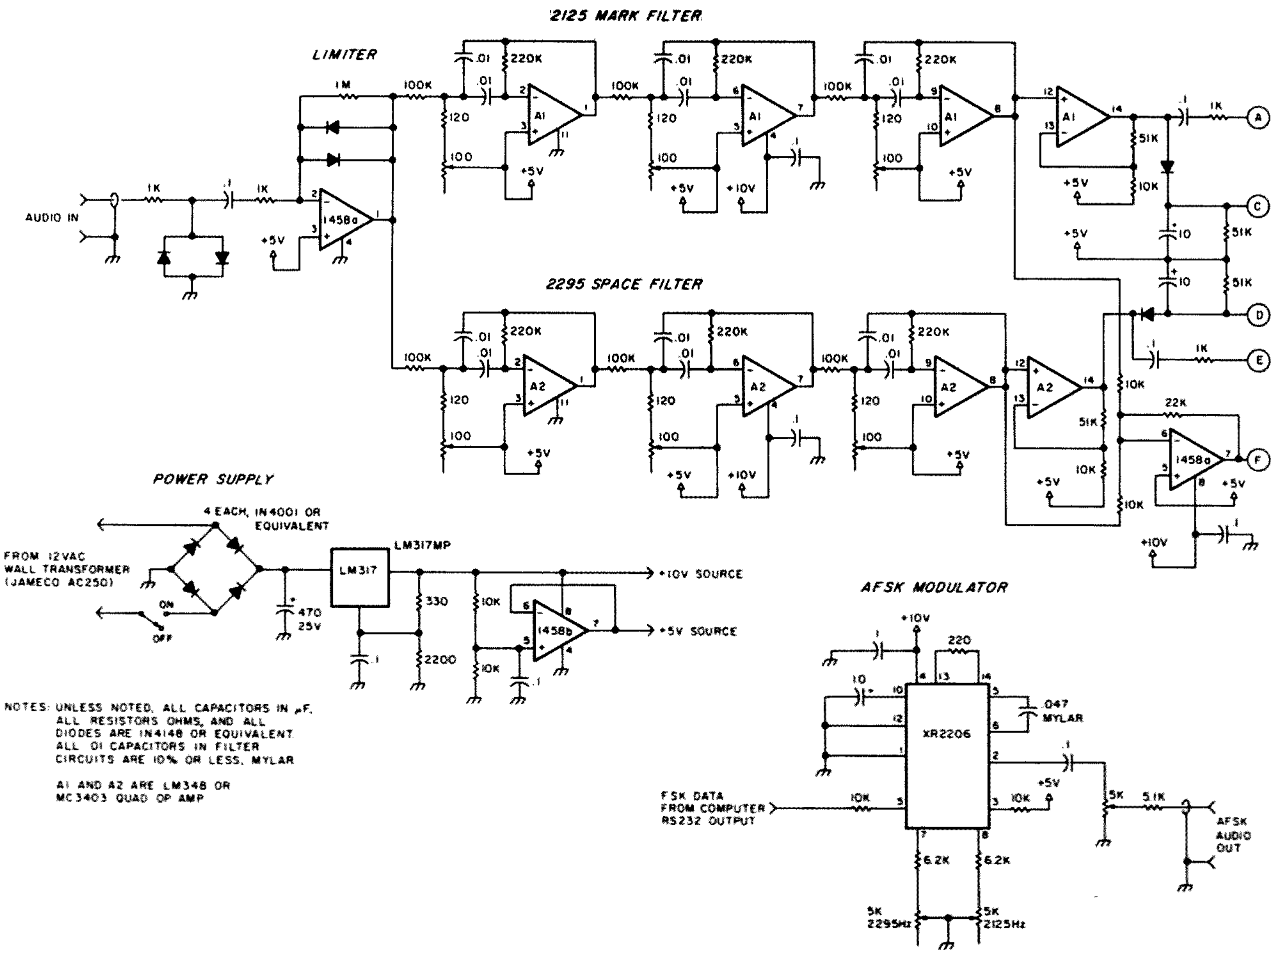

Fig 1(a). Filters, power supply, and modulator for the 170-Hz shift RTTY modulator/demodulator.

Clay Abrams K6AEP
1758 Comstock Lane
San Jose CA 95124

One of the most powerful low-cost computers available to date is the Radio Shack TRS-80C Color Computer, affectionately called the CoCo. The CoCo computer has grown in popularity over the past few years due to its low price and ease of expansion. It's hard to imagine how such a powerful computer can be sold at such a low cost.

Cost, however, is not the major attribute of this little computer. Tandy made a wise choice in selecting the 6809 processor for use in the CoCo. This processor is one of the least understood microcomputers available to date. It has many features which do not exist in any other microcomputer. Since my topic here is really amateur radio teletype, I'll show how this processor stands in a class by itself later in this article.

I would like to reach a couple of objectives in this article: to provide a small RTTY program which can be used as is or modified to add any features desirable, and to discuss a simple RTTY interface which can be purchased or constructed to get you on the air at minimal cost. But first, a little background on how this program was written.

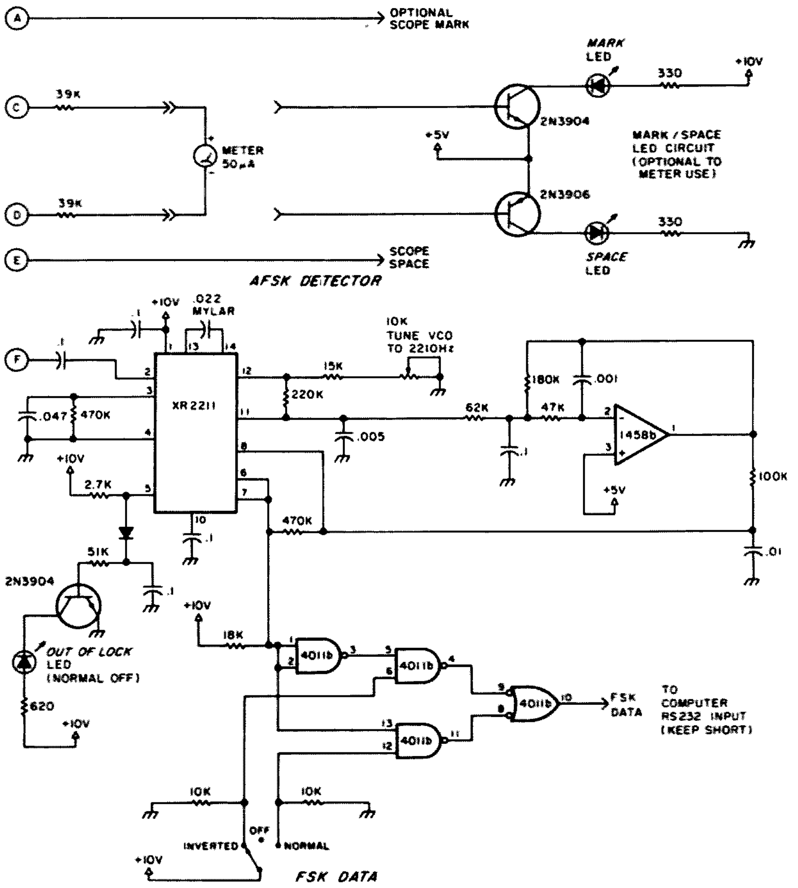

Fig. 1(b). Detector and tuning outputs for RTTY modulator/demodulator.

Program Background

Back in 1976, I wrote my first crude RTTY program for the South West Technical Products 6800 system. Do a few of you old-timers remember this computer? One can be seen from time to time even in flea markets. It became obvious in those early days that computers were the way of the future. The only big challenge to manufacturers was to drop their prices to a reasonable level.

After a few years of experimentation and further developments, I succeeded in writing a total of six RTTY programs for the 6800. In this period, I learned a lot and made a lot of mistakes. In 1980, I upgraded to the 6809 processor, which was a big step. But after a few months it became obvious that this processor was designed to be friendly and easy to program—unlike the 8080, 8088, Z80, 9900, and the 6502.

Probably the biggest moment in the history of the 6809 was Tandy's announcement of the CoCo in late 1980. As you might have guessed, I had one of these computers a few weeks after the announcement. In those days, a 4K computer was the norm, and one of my first challenges after developing some SSTV software was to write a RTTY program which would run on a 4K CoCo. I was very surprised to find that the CoCo was ideal for amateur radio applications. It was free from RFI susceptibility, even with 1 kW, and no birdies could be found on the HF receiver on any band. After the horror stories I heard about the TRS-80 Model I and other popular, expensive, well-known computers, I was very happy.

In this article you will see the results of my early RTTY efforts. Since this time, other RTTY programs have been written with greater features, but the basic principles are the same.

One point which must be emphasized is that if you desire to write programs for real-time high-speed applications, you should use machine language. A few RTTY programs have been written in Basic, but you can never achieve satisfactory results with it. Basic interpreters are too slow. The use of FORTH or the C language should work almost as well as machine language.

When designing a RTTY application program, a few fundamental decisions must be made even before starting to flowchart the code. These decisions are related to the hardware you use. In hardware selection, you have two possibilities. The first is to design the hardware to perform all the serial-to-parallel RTTY conversions. This requires the use of relatively complex hardware and relatively easy-to-write software. The advantage of this technique is for the manufacturer. The hardware costs can be passed along to the consumer and the manufacturer will not have to spend as much time writing software. This type of system has other advan-

Fig 2. Program listing.

tages, like hardware time and date clocks and the ability to print text while receiving RTTY.

The second hardware choice is to do all the serial-to-parallel decoding in software and allow the computer to be attached to any available TU. This technique is the best for the consumer. The costs are much less in this choice, but the burden of the system's performance is placed on the back of the programmer. This type of programming is very difficult and separates casual programmers from professionals. To do this type of programming requires the patience of a saint and the determination of a bulldog.

I will describe here a program which uses the simple hardware concept and demonstrates some of the techniques which can be used in more elegant software. Hopefully, this article will perform three functions:

1) Be a teaching tool to show how simply RTTY can be programmed.

2) Demonstrate some of the programming techniques which place the 6809 processor in a class by itself.

3) Allow a ham with a limited budget and a minimum computer to get on RTTY for the least cash outlay.

The System

To receive RTTY on today's crowded ham bands requires some sort of hardware interface with good input filtering. This type of interface to the computer is called the TU, or terminal unit. This interface is used to remove adjacent channel interference and general background noise. The only requirement for this interface is that its output and input are compatible with standard RS-232 levels. RS-232 has no meaning other than that the voltage levels are greater than plus or minus 8 volts. The program listing assumes that the TU has RS-232 compatibility and attaches to the CoCo through its RS-232 port. Later in this article, a sche-

matic of a simple TU will be discussed which can be home-brewed at a low cost.

The only other necessary feature for the system is that the CoCo must have 4K or more RAM. Extended Tandy Basic is not required since the program is written in machine language. Attached to the computer must be a TV set for display and a tape recorder to save or load the program.

The Software

My seventh attempt at developing a RTTY program is shown in the program listing. This program can be keyed in directly from the listing in object form or keyed in in source form and assembled to create an object code. The object code is the actual machine-language programming which causes the computer to do its tricks. To key in a program, the left-hand column is the address in memory where the instruction is stored. The following bytes are the actual bytes in memory. For example, the RTTY program's first instruction is 1F and is loaded into memory at address 0600. To key in a program like this requires the use of a second program called a monitor. You can obtain a monitor program from commercial sources or write your own in Basic. One of the most important features of the RTTY program is that it can be saved anywhere in the CoCo's memory without changes. This means that you can key the program into address 1000 or 2000 hex and it will run without changes. The 6809 microprocessor is the only computer which allows you to do this. All other processors require that the program must be reassembled at another address to make it run. This feature is called Position Independent Code.

To understand how to write a program to take advantage of this feature is a little difficult. I'll try to point out how it is done as I proceed through the program description.

Program Description

The program was written to perform three functions: receive RTTY, transmit RTTY, and issue a CW ID at the end of a transmission. Each of the functions can be broken down further into smaller parts which change RTTY speeds, allow for program option selections, and do general housekeeping. Before jumping into the description of these various functions, let's discuss how the program achieves position independence. I'll next go into each of the functional program parts.

Position Independence. The RTTY program uses two means to achieve program position independence. The first technique is use of the user stack, or U register. The user stack is similar to the system stack, but it can be used in the 6809 for two purposes. One use is as a third index register. The U stack can also be used as a pointer in memory for the storage of program variables. This is how U is used in this program. When the program is first executed, the system stack is placed slightly below the user stack. This system stack position is determined by Tandy Basic and varies as a function of the size of memory. Typically, it is in the upper 256 bytes of available memory. If program variables are referred to by this pointer, their position in real memory can be variable. Some of the variables in the RTTY program use this technique.

The second technique is the use of the LEA or Load Effective Address instruction. This instruction allows for an index register to be loaded with the address of a program variable relative to the program counter (PCR) wherever it may be in memory. For example, the LEAX MENU,PCR will load the address of MENU into the X register. The PCR portion of the instruction means that the load is relative to the location in memory where the program is currently exe-

cuting. This programming technique allows the program to be moved around in memory.

General Housekeeping. When the program is first executed, the start routine sets up RAM delay constants, places a message on the screen, and asks for a CW ID to be transmitted. The CW ID can consist of up to 15 characters. As each character is entered into the keyboard, it is translated to CW and placed in a buffer at the end of the program called BUF. Next, the primary menu is flashed on the screen of the CoCo. This menu allows for the selection of receive, transmission, or speed selections.

All communications to and from the program are through INEEE, OUT, and OUTEEE routines. These routines use the standard Radio Shack I/O vectors in the Basic ROM. It would be possible to change these vectors to any 6809 system and the program will function.

RTTY Receive. RTTY can be received by the program as either 8-bit ASCII without parity or 5-bit Baudot. Either mode can be selected by the SPEED routine. When the program is first initialized, a speed of 60-wpm Baudot is selected. This is accomplished by the IN60 routine which adds the appropriate constants to BRATR1,2 and BRATD.

To receive RTTY, the mainline routine RECV is selected. When selected, the routine first checks to see if ASCII or Baudot is chosen. This is accomplished by checking MASK. If this value is zero, the mode is Baudot; if anything else, the mode is ASCII.

The mainline Baudot receive routine is RECT1, and ASCII is RECT4. These routines continuously receive RTTY and display the results on the screen until a key is struck on the keyboard. The ASCII routine has a little abnormality in that once it is selected, either a signal or

more input data will allow deselection of the routine while pressing a key.

The receive routines function by sampling the RS-232 input and looking to see if the port is high or low. If software delay is executed, you can sample, delay, then sample again for all data bits. If the bit is off, it is a data bit; if on, it is not a data bit. As each bit is received, a data byte is formed in which the results are stored. When complete, this data byte can be displayed on the screen or converted to ASCII from Baudot and then displayed.

The Baudot-to-ASCII conversion routine is located at FINDA. The routine expects the Baudot code to be stored in CODE. The routine takes the Baudot byte, masks out the high-order bits, and adds the results to an address located in the X register. The address in the X register is the base address of UD1, which is the look-up table. This table is organized to allow the byte to control program flow based upon the Baudot code received. After completion, this routine places the resultant ASCII code in a variable called BAUD. To add a few complications to this process, some tests must be made to determine if the Baudot is uppercase or lowercase. This is accomplished by checking the UD value in RAM. This value determines whether the Baudot character is a figure or a letter.

Transmit RTTY. If you understood receive RTTY, then transmit should be easy. This technique is the opposite of receive. The mainline routine for transmission is FIFO. This routine normally stays in a polling state looking for a keyboard input. If the input is a special character, any one of five different functions can be selected. If the keyboard entry is a standard character, then it will be transmitted. The five possible functions are:

- Clear key—Return to mainline routine.

Parts List

Qty.	Item	Qty.	Item	Qty.	Item
1	LM317MP regulator	2	6.2k	1	.047-uF ceramic
2	LM1458 op amp	10	10k	15	.1-uF ceramic

- Less-than key—Xmit a CW ID.
- Plus key—Load station buffers.
- Greater-than key—Xmit station buffers.
- Equal key—Xmit 15 RYs.

Let's continue on the RTTY transmit before discussing the other functions. When a character is to be transmitted, the FXMT routine is called. This routine places the ASCII character from the keyboard entry into ASCH and then calls the TRTTY routine. This routine first determines if the character is to be transmitted as ASCII or Baudot. If it is Baudot, the FINDB routine is next called. This routine functions in a similar manner as FINDA. Once the Baudot character is found, a test determines if an upper- or lowercase shift should be made. This is accomplished by the UD routine. A comparison is made with the last shift sent and, if necessary, another shift is made to the opposite sense. Upon completion of this test, the Baudot bits are shifted into the carry and transmitted as RTTY. Between each shift, a delay is made to adjust to the correct speed.

If ASCII characters are to be sent, the ASCIO routine is called and the ASCII keyboard entry is transmitted directly as RTTY.

Returning to the five option selections, they can be summarized as follows. The CW ID is transmitted by the CW routine. This routine functions similarly to transmit RTTY. The CW byte is loaded into the A accumulator and the data bit is shifted into the carry and sensed as a transmit mark or space. The lower three bits in the CW transmit byte indicate the number of CW bits to be transmitted. Various delays are made in the software to proportion the relationship between the dot and dash.

The plus command loads three station buffers with characters. These buffers can be preloaded with messages and saved on tape with the program. Two of the station buffers have 254 bytes; the third has 125 bytes. This restriction was due primarily to the RAM limitations of a 4K computer. The buffer sizes and numbers can be changed to suit individual taste. You are limited only by the size of RAM in your computer. One feature of the load command is that RTTY is transmitted as the buffer is loaded.

The greater-than key is used to transmit station buffers which have been loaded previously.

The equal-to command is used to transmit a series of RYs to test out the equipment at both ends of the path.

Program Assembly and Saving

As discussed earlier, the program can be loaded directly into memory and saved as a binary file on tape by a machine-language monitor or from Extended Tandy Basic. The best way is to key the source into the computer using a text editor, then use an assembler to generate object code. This technique will allow for ease of modification at some later date. A good idea might be to load up the station buffers with text which you normally send on RTTY and save the complete text and program on tape.

If you wish to load this program on Tandy disk, it must be placed above address $0F00 and then saved on disk. The program can also be placed on EPROM. This will require a change to the program. The text buffers and the program RAM constants must be changed to a location in RAM and the program assembled at the ROM address. This is another advantage of using an assembler to create the object code. The program uses 1609 bytes of code, which means that it can fit on one 2716 EPROM. The program can then be placed in a ROM cartridge if assembled at location $C000. The RAM buffers could be placed at $0600 and loaded or saved from tape.

RTTY Interface

Almost any RTTY TU interface will function with this program. Numerous articles have been published in many magazines on this subject. The only requirement is that the input and output from the computer be through the RS-232 interface on the rear of the computer. All that is required is a 4-pin DIN connector, a cable, and a TU. The CoCo is quite tolerant; it will accept standard TTL voltage levels or RS-232 levels. A number of commercial firms produce interfaces which are advertised in this magazine. For some of you devoted home-brewers, see Fig. 1, a schematic of a simple RTTY interface which was provided to me by Dynamic Specialities.

RTTY Interface Circuit

The interface is quite straightforward and uses easy-to-obtain components. The interface can be constructed on perfboard or a pluggable prototype card and placed into a cabinet. On RTTY receive, the circuit uses two bandpass filters of 2125 and 2295 Hz respectively to filter the RTTY tones. The filtered tones are connected to a simple AFSK detector which consists of an XR2211 and some drivers which are connected to the RS-232 input of the CoCo.

A switch is provided on the buffer circuitry after the XR2211 demodulator. This switch is optional. Once the correct polarity of the signal is determined, the circuit can be hard-wired, thus eliminating the polarity switch.

The tuning meter on the output of the filters is required due to the sharp response of the filters used. When adjusted correctly, a mark tone will swing to 20 microamps and a space to 40 microamps. During normal RTTY reception, the meter will read 40 microamps.

To transmit RTTY, the interface uses an AFSK modulator. This modulator consists of a single XR2206 IC. This IC takes an output from the RS-232 interface on the CoCo and converts the voltage to an audio tone. This tone is either 2125 Hz (mark) or 2295 Hz (space). To adjust the AFSK generator, ground pin 9 of the XR2206 and, by use of a counter, adjust the output to 2125 Hz. Next, place 10 volts on pin 9 and adjust for 2295 Hz.

Next, connect the modulator output to the TU input and adjust the mark and space filters.

To connect the TU to a ham transceiver is a simple process. Connect the transceiver's headphone output to the TU's input. Connect the AFSK output to the microphone of the transceiver. Switch the transceiver to lower sideband. Presto, you are now on RTTY.

Conclusion

The RTTY program described in this article was a lot of fun to develop. Its performance leaves a lot to be desired in features and usability. A very desirable function is split-screening of the buffers and receive data. This feature is very tricky to program and requires the use of interrupts. If you are interested in more advanced RTTY, SSTV, WEFAX, or CW amateur radio software, drop me a line for information on its availability.

I would like to thank Dynamic Specialties for providing the TU circuit. An advanced version of the TU is available in PC board form and includes a state-of-the-art automatic digital filter. Contact Dynamic Specialties, PO Box 20903, San Jose CA 95160, for more information.■

73 INTERNATIONAL

Each month, 73 brings you amateur radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73: Amateur Radio's Technical Journal, *Pine Street, Peterborough NH 03458, USA, Attn: Avery L. Jenkins WB8JLG.*

BANGLADESH

M. Saifud Dahar Shahid
President, BARL
GPO Box 3512
Dacca, Bangladesh

BARL ADMITTED TO IARU

The Bangladesh Amateur Radio League (BARL) applied for membership in the International Amateur Radio Union some time back. In a special issue of *IARU Calendar* (no. 108, December 8, 1981), the headquarters made a proposal concerning the admission of BARL. *Calendar* no. 111 (March 24, 1982) published the results of the election of BARL.

It is very encouraging to note that all of the 49 votes received by the IARU headquarters were in favor of BARL admission. Bangladesh is the 115th member society of this international body.

BARL JOINS IARU REGION 3 ASSOCIATION

After joining the IARU, BARL applied for membership in the IARU Region 3 Association. In the Fifth Conference of the Region 3 Association, held in Manila, Philippines, this application was considered. BARL has now been officially informed by the Region 3 Association that it has been accepted as the 18th member of the Associaton.

IARU VP VISITS DHAKA

Carl L. Smith WØBWJ and his XYL, Terry, visited Dhaka recently. In his report, the IARU vice president mentioned that "a continued organizational development of the BARL was noted in Bangladesh."

This is the second time an IARU officer visited Bangladesh. In 1981, BARL had a visit from David Rankin, then-secretary and present chairman of the Region 3 Association. During his visit, David met with the high officials of the T&T Board and the Wireless board, the Minister for PT&T, the State Minister for Science and Technology, and the Prime Minister. A TV interview of David was also recorded for broadcast on April 26, 1981.

These visits certainly contributed to the promotion of amateur radio activities in Bangladesh.

BARL PRESIDENT VISITS USA AND SRI LANKA

BARL President Saif Shahid, during his visit to the USA in April, 1982, made contacts at the IARU headquarters at the ARRL. He spoke with Victor C. Clark W4KFC and David Sumner K1ZZ about the development of amateur radio in Bangladesh.

On a separate visit, Saif Shahid and Tariq Hasan, another member of BARL, visited Sri Lanka to attend a two-week-long seminar on microcomputers. During their stay they were invited by John Amaratunga 4S7JA (RSSL president) to a dinner followed by a visit to 4S7EA's shack for a demonstration of a RTTY QSO on a VDU. BARL looks forward to a long-lasting friendship with RSSL.

BARL APPLIES FOR CLUB STATION LICENSE

BARL has applied to the Wireless and Frequency Allocation Board for issuance of an ad hoc amateur radio license for a BARL headquarters club station. It is understood that the application is under active consideration by various government agencies. BARL expects to have the club license in time to enable it to participate in various activities during World Communications Year.

In the second Bangladesh Electronics Symposium, a paper titled "Role of Amateur Radio in Bangladesh" was presented jointly by Saif Shahid and Nizam Chowdhury. The technical session was chaired by Air Vice Marshal Sultan Mahmood, Chief of Air Force Staff. The paper highlighted the various aspects of amateur activities and the prospects of such activities in the technical advancement of a developing country like Bangladesh.

CANADA

Cary Honeywell VE3ARS
PO Box 2610, Station D
Ottawa, Ontario K1P 5W7

By the time most of you read this, the summer will be gone. In some places in Canada the summer is measured in days rather than months. This does not stop clubs and organizations from holding their annual flea markets and hamfests. Most of ours cannot match the Dayton or Rochester hamfests, but for Canada, they come close.

In the eastern part of the country, the big ones are held near the Toronto, Ontario, area: The Whitby area holds one in late April or early May, while Guelph holds theirs in the first week of June. July sees the Southern Ontario Hamfest, held at Milton, just west of Toronto. One of the biggest hamfests in Canada is the RSO convention, held each fall. This year, Toronto hosts this event.

In the contest area, the CARF-sponsored Canada Day Contest was held on July 1, this being Canada's birthday. Although not as well advertised this year, the event made most bands very active with Canadian stations.

In my August column, I was discussing TRC24, the syllabus for amateur examinations, and how the efforts of the amateur community were wasted. Well, it seems the DOC heard our cries of anguish. Shortly after a meeting between CARF officials and the Director General of Telecommunications for the DOC, both CARF and the Canadian Division of the ARRL were asked to submit proposals to amend the issue. CARF President Don Slater VE3BID and ARRL Canadian Director Tom Atkins VE3CDM agreed on a method of obtaining a consensus before the June 10th deadline which the DOC had specified. The cooperation between the two groups was well under way when the Canadian vice director Harry MacLean VE3GRO, intervened and asked for the DOC to extend the deadline. So much for cooperation. The matter is still up in the air, and I will let you know how things develop.

On other matters, the Canadian Amateur Radio Federation held its Annual General Meeting during May. At the meeting, two new directors were introduced: Robert Sondack VE2ASL of St. Luc, Quebec, well known in AMSAT circles in that province and also a director of the Quebec provincial amateur association, RAQI; and Leigh Hawkes VE1ZN of Dartmouth, Nova Scotia. Leigh is also well known in Canada as one of the most prominent workers on cable television interference. These gentlemen join Craig Howey VE3HWN of Waterloo, Ontario; Geoff Smith VE3KCE of Aurora, Ontario; Norm Waltho VE5AE of Moose Jaw, Saskatchewan; and Peter Driessen VE7AB of Surrey BC in the job of directing Canadian amateur affairs for the federation. Two departing directors, Nate Penny VO1NP of Shoal Harbour, Newfoundland, and Raymond Mercure VE2BIE of Hull, Quebec, were congratulated on a job well done and wished good luck. All other positions in the federation remain the same.

I would like to hand out a couple of laurels this month. First, to Bill Deacon VE3BDO. Bill has been writing a superb series of articles called "Life on the Ocean Wave" for *TCA* over the past few months. A steady stream of letters has been coming in to the editor of *TCA* (me) in support of this assessment. The Society of Wireless Pioneers is preparing to reprint the series soon, and I hope more of you will get the chance to read these memoirs of a radio operator in the pre-WWII era of radio.

My second laurel goes down east. Across Canada, we have many QSL bureaus, both outgoing and incoming. The best known outgoing bureau is the CARF National QSL bureau at Box 66, Islington, Ontario. The best known incoming bureau is in Halifax, Nova Scotia, and is run by Britt Fader VE1FQ. For many years the Canadian Division ARRL's central bureau was run by Britt and even though his is only a provincial operation now, he still receives and forwards many QSL cards. A tip of the hat to Britt Fader VE1FQ.

By the way, if you are wondering why the CARF QSL bureau is not in the *Callbook*, the answer is simple. It is not the ARRL bureau.

BRAZIL WINS ITU TROPHY

The ITU Contest is sponsored every second and third weekend of May to commemorate the World Telecommunications Day (May 17th). The ITU Trophy goes to the country with the highest aggregate score. (Brazil's total was 442,825.) This is determined by the top five single-operator scores plus the top multi-operator scores, both on phone and CW. The trophy remains in the possession of the representative national association of that country for one year. It is retired by the country winning three consecutive times or five intercalated times. (See box for scores.)

Other trophies won were as follows. Single operator: Gold—RX7CF for CW and UP2NK for phone; Silver—PY1DOQ for CW and OE3ITU (OE2VEL) for phone; Bronze—EA2IA for CW and HA5WE/7 for phone; and Silver Plates for multi-operators LZ1KDP for CW (257,096 points) and UKØQAA for Phone (364,984 points).

WORKED ALL PP AWARD

Sponsored by LABRE/Goias, the WAPP

Award is available to all licensed amateurs for confirmed contacts with : (a) PY1 stations prefixes (PP1, PP2, PP5, PP6, PP7, and PP8). The PP2 contact must be with a station located in the city of Goiania. The award is to celebrate the centennial of the city of Goiania, in Goias State.

All contacts must be made during 1983, on any band and any mode. Send GCR log of stations worked (call, date, time, band, mode, and report) and 10 IRCs for mailing expenses, to LABRE/Goias—Coordenador De Diplomas, PO Box 676, 74000 Goiania, GO, Brazil.

There are no special endorsements for the WAPP Award.

SWL: Same rules.

CWRL AWARD

Sponsored by the Lakes Region of the Rio de Janeiro Radio Club, the CWRL Award is available to all licensed amateur for confirmed contacts with: (a) PY1 stations whose first suffix letters form the phrase: *Araruama—onde o sol passa o inverno* (meaning: "Araruama—where the sun spends the winter), and (b) three CWRL members (any prefix or suffix).

Contacts must have been made after January 1, 1983, on any amateur band. Only two-way CW mode.

Send GCR log of stations worked (call, date, time, band, mode, and report) and 10 IRCs for mailing expenses, to CWRL Bureau, PO Box 91, 28970 Araruama, RJ, Brazil.

There are no special endorsements for the CWRL Award.

SWL: Same rules.

CWRL members are PY1AEE, PY1AFA, PY1ASI, PY1AZG, PY1BPI, PY1BUG, PY1BVY, PY1CC, PY1COA, PY1DEA, PY1DFF, PY1DGB, PY1DJY, PY1DMQ, PY1DMX, PY1DPG, PY1DQV, PY1DWM, PY1EBH, PY1EBK, PY1ECL, PY1EWN, PY1GO, PY1TCJ, PY1TZ, PY1VMW, PY1VEH, PY1VTN.

MALPELO (HK0TU) DXPEDITION

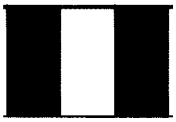
In the second week of October, 1983, for five days, there will be a DXpedition to Colombia's Malpelo Island, located at 3° 59' 07" latitude north, 81° 34' 27" longitude west, in the Colombian Pacific Ocean territorial waters. The DXpedition is jointly sponsored by the Colombian Radio Amateur League (Liga Colombiana de Radioaficionados) in cooperation with the Colombian navy, which will supply the transportation and the required logistics support.

The main goal of this extremely interesting DXpedition (Malpelo Island being the fourth most important valid country for the DXCC award) is to publicize Colombian radio amateur operations. This year the Liga Colombiana de Radioaficionados is celebrating its 50th anniversary.

Because of the roughness of the terrain, the DXpedition organizers required all participants to have perfect health, good physical fitness, and, if possible, previous experience in this kind of DXpedition. They also have to be younger than 46. However, as is well known, some of the "oldies" are tougher and better performers in the field. A main team of 15 Colombian operators is being carefully selected by the League.

The transmitting frequencies are: CW—28,025; 21,025; 14,025; 7,025; 3,525; and 1,825 kHz; phone—28,595; 21,295; 14,195; 7,085; 3,795; and 1,825 kHz. Also, there will be extensive experimentation via satellite on 146.460 MHz. The QSL manager will be internationally famous Beto Rojas HK3DDD.

Though an inscription limit was locally set till the end of May, 1983, written applications from foreigners (on a restricted basis) are welcomed by the League via PO Box 584, Bogota, Colombia, South America.



FRANCE

Claude Guee F1DGY
11 Rue Emile Labiche
28100 Dreux, France

TERRES AUSTRALES FRANCAISES AWARD

For three contacts with these different lands, or four contacts to receive the golden star "EXCELLENCE" award: FB8FX (Kerguelen Island), FB8Z (St. Paul, Nouvelle Amsterdam Island), FB8W (Crozet Island), and FB8Y (Terre Adelie).

Only contacts after April 1, 1946, are valid. The fee is 10 IRCs.

DEPARTMENT ET TERRITOIRES D'OUTRE-MER AWARD

For contacts with these nine different prefixes: FM7 (Martinique), FG7 (Guadeloupe—St. Martin, St. Barthelemy), FY (Guyane), FR (Reunion—Glorieuse, Europa, Tromelin, Juan de Nova), FP (St. Pierre et Miquelon), FK (Nouvelle Caledonie—Pins, Chesterfield, Huon, Loyautes), FH (Comores), FW (Wallis-Futuna) and FO (French Polynesia).

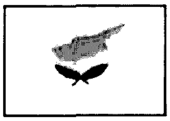
Only contacts after January 1, 1982, are valid. The fee is 10 IRCs. For these two awards, the manager is Alain Duchauchoy F6BFH, 21 Rue de la Republique, 76420 Bihorel, France. The usual conditions apply to these awards (certified log extract, no QSL requirement).

OTHER NEWS

At this moment, there are about 12,000 French radio amateurs. Despite the fact that France was once very advanced in this hobby, this one is not as popular as it should be! Especially if we compare ourselves with other countries.

Besides the conventional traffic on the HF bands, the upper bands are more and more used as follows:

- 2 meters with repeaters mainly, but also SSB, satellites, RTTY, SSTV, and CW.
- 70 cm with repeaters also (many promising projects), fast scan TV, SSB.
- 23 cm—the new frontier—some repeaters are scheduled. Currently, most activity is on FM, SSB, and fast-scan TV. Aerials are generally F9FT 23-element beams.
- 10 GHz—This band had its heyday some years ago with Gunn diodes. Nevertheless, fans are numerous and there are regular skeds on FM, SSB (fast-scan TV also).
- Otherwise, microcomputing is now a very active branch for hams. Many radio clubs are the first school for newcomers.
- Two associations help the French ham. They publish two magazines: Reseau des Emetteurs Francais (REF) publishes *Radio REF*, and the Union des Radio-Clubs (URC) publishes *Ondes Courtes Informations*.



CYPRUS

Aris Kaponides 5B4JE
PO Box 1723
Limassol, Cyprus

AN OVERVIEW: AMATEUR RADIO IN CYPRUS

At the present there are about 280 amateur radio licenses with the 5B4 prefix and a dozen or so with the ZC4 one. The 5B4 licenses are issued by the Republic of Cyprus and the ZC4 by the British bases' authorities in Cyprus.

Although someone would expect that this number of amateurs is high compared with the 630,000 population of the island, not many amateurs are active on the HF bands. All amateur radio acitvity comes from the southern part of the island, which is under the control of the government of the Republic of Cyprus, and the great majority of amateurs are Greek Cypriots. On the northern part of the island, which is under Turkish occupation, there is no amateur activity at the moment. Occasionally there is some activity there by United Nations personnel operating with a 5B4 license.

There is only one type of license which permits use of all bands and modes. Licensing conditions and restrictions are very similar to the old British regulations—Cyprus being an ex-British colony. On the HF bands, only about a dozen stations are active at the moment, mostly on 20m, 15m, and 10m. The rest of the stations are either not active at all—some do not even own equipment—or operate on 2m only.

To help amateurs without equipment as well as prospective amateurs, who are usually young boys, a few keen amateurs have established one club station in each city. These stations are active once a week for only a few hours. These clubs also offer instruction by suitably qualified amateurs to help prospective amateurs pass the radio amateur examinations. The tests are given by the Ministry of Communications and Works, but the British Radio Amateurs Examination is also accepted.

Most 5B4 stations are on SSB 20m, 15m, and 10m, but one or two of them can be found on 75m and 40m. On the last two bands, 5B4EP and 5B4JE are still active. During the winter, 5B4EP, 5B4JE, and 5B4PW occasionally operated on 160m.

As far as I know, only about four 5B4 stations are using CW at the moment and perhaps an equal number of ZC4s. On RTTY, only two stations are active, 5B4CV and 5B4HF, mostly on 20m. During the last few months, 5B4CV also was active on SSTV, and after a short break he will soon be operational again with a home-brew camera.

Most of the equipment used by Cyprus amateurs is commercial and imported, but there also is some home-brewing going on, such as tuners, linear amplifiers, small transceivers, test gear, antennas, etc. Leaders in home construction at the moment are 5B4BS, 5B4CV, 5B4AZ, 5B4AH, and 5B4DV.

The Cyprus Amateur Radio Society (CARS), a member of the IARU, besides other activities runs a QSL bureau which is very conscientious but also very slow, through no fault of its own. The reason is purely economic. The QSL manager has to wait a long time to collect enough cards for a certain country so that postage will be cheaper. CARS is not so strong financially because not all licensees are members of CARS. My advice for amateurs, if they want to get a quick QSL card, is to QSL direct. Using the bureau takes as long as three years sometimes.

I do hope that I have given you a general idea about amateur radio in Cyprus. In future columns, I will give you information about awards, temporary licenses, and current 5B4 activities.

From Cyprus, the island of Aphrodite, goddess of love, we hope to keep you informed regularly.

Aris 5B4JE.

THE UK SCENE

For as long as I have been reading *Radio Communication*, the monthly journal of the Radio Society of Great Britain (known to everyone as *Radcom*), there has been a monthly column called "Technical Topics." This 3-to-6-page potpourri (known throughout G-land as "TT") has provided a forum for new, sometimes untried, ideas. It reports on the proceedings of appropriate learned bodies such as the IEEE, it summarizes foreign amateur radio journals including those written in non-

English languages, and it suggests new circuit ideas.

A recent TT in *Radcom* included the following variety of subjects:

● Electro-Magnetic Compatibility (EMC) and its supplanting of RFI and TVI as the main external factor affecting the operation of amateur stations.

● Screening and filtering and the need to minimize out-of-band or unnecessary in-band radiation at source. The work done by Philip Rand W1DBM many years ago was discussed again.

● A 20-A power supply following the KISS (Keep it Simple, Stupid) principle and using only 17 components. The originator of the circuit, G4HYD, counsels the underrating of components in such systems.

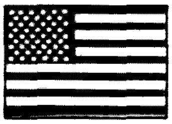
● High-power MOSFET amplifiers as originally presented by K7ES/OH2ZE in *QST*.

● New loop antennas raised again the thorny problem of defining HF antenna performance. Systems such as the G2PL special (turned-over quad) seem to indicate that a horizontal loop antenna can provide effective low-angle, DX-working even when the wire is only a few feet above ground. However, TT also promulgates the theories that (a) it would be impossible to devise any piece of wire that would never result in DX when conditions were very good, and (b) when an amateur puts up a new antenna he tends to become more active and this results in more and better DX until at least the first flush of enthusiasm wears off.

All very interesting and thought-provoking stuff—but why report the contents of an average TT in "The UK Scene?" The edition to which I refer is remarkable for two reasons. First, it is twenty-five years since the column started and any silver jubilee is worth celebrating (as any readers lucky enough to be in the UK in 1977 will testify). Second, TT has been written for all those 25 years by the same author, Pat Hawker G3VA. Quite an achievement, I think, to cover virtually the entire era of silicon and the parallel demise of thermionics without becoming boring or repetitive.

It seems that there may have been some substitution of candidates for the Home Office Morse test in recent months. (Passing the test at 12-wpm send and receive is a prerequisite of a full HF-class A license.) The authorities have "with some reluctance" introduced new vetting procedures for prospective amateurs sitting the test. It is now necessary for some positive means of identification such as a passport to be produced. Presumably, a document bearing a photograph will be necessary.

The Morse test is carried out by the Maritime Branch of British Telecom (formally the Post Office) at a coastal radio station. Although informal in nature, the required standards have not been allowed to slip. Taking the test currently costs US$22 and may involve quite an amount of traveling, as many BT coastal radio stations are now unmanned and operated remotely.



GUAM

J. T. Pogue KH2AR
68 Banyan Circle
FPO San Francisco 96630

THE VIEW FROM GUAM

Many hams around the world are familiar with the two dots on our globe that share the name Cocos Island. The first, off Costa Rica's western shores, sports the TI9 callsign prefix. The other Cocos Island (also known as Keeling Island) is located in the eastern Indian Ocean, and hams operating from there use the VK9Y prefix.

Here on Guam, however, we have our own Cocos Island. Located just over two miles from Guam's southernmost village of Merizo, the narrow sliver of land points like a finger extending into the crystal blue waters of the Philippine Sea.

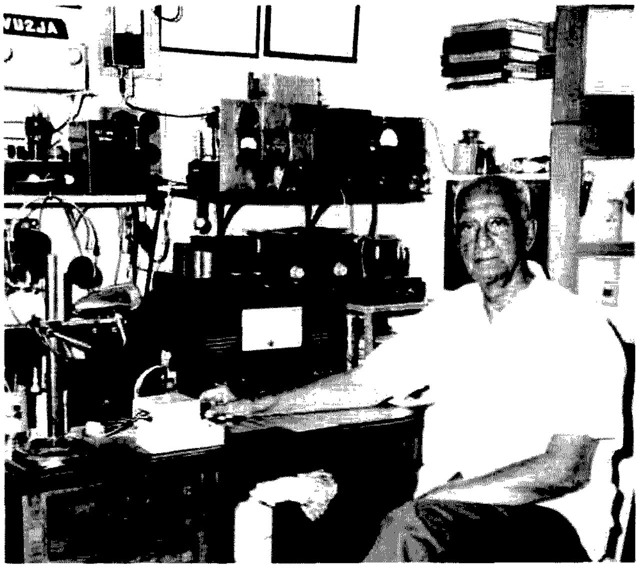
Shortly after WWII, the US Coast Guard built a LORAN "A" station on the island. However, with the advent of the LORAN "C" system, the Cocos station was closed and much of the island was turned over to enterprising developers. Today, a beautiful beach, a picnic area, a small zoo, and plans for a resort hotel with casino make Cocos Island a popular destination for tourists and residents alike.

Recognizing this popularity, the Guam chapter of the American Red Cross has, since 1981, held an annual fund-raising event called the Cocos Challenge. The object of the challenge is to swim, snorkel, sail, paddle, or in some other way travel the distance from Cocos to Merizo. And, for the third consecutive year, the Red Cross requested assistance from Guam's hams to help ensure the safety of the participants. Thus, at 6:00 am on May 15th, 10 hams from around the island met with their 2-meter gear to help make the third annual Cocos Challenge a little safer for those in the water.

Preston "Al" Allen KH2BB acted as net control at the officials' tent, while Dave Beck KH2BD kept an eye on things at the Merizo Pier finish line and Ann McDaniel KG6JKN helped out at the starting line on Cocos. The remaining operators, Bill Michling KH6II, Russ Albee WB7EHU, Gerry McDaniel KG6JHN, Carl Wegner KG6JKV, Dave Chartier W1YRM, Gary Resta N2BMV, and Jim Pogue KH2AR took their places in the station. Rescue and Coast Guard boats were present to provide timely and reliable communications throughout the event.

Although no serious problems arose during the race, a few swimmers who tired early were pulled from the water and transported to shore.

Perhaps the highlight of the day was when one of the "Crazy Craft," an old VW car floating on pontoons, proved to be too unwieldy to make the entire trip to Merizo. The Coast Guard boat on the scene was heard reporting to their Rescue Center, "... be advised, we are headed for Cocos Island with a 1967 Volkswagen in tow." After a lengthy pause, the Rescue Center haltingly replied, "... say again?"



OM J. A. Faithful VU2JA.

Al KH2BB operates net control during the 3rd Annual Cocos challenge.

INDIA

MEET JOE FAITHFUL VU2JA

There are a few valid reasons why we want you all to meet OM Joe Faithful VU2JA. He is one of the few hams who had the luck and opportunity to communicate with spark transmitters, carborundum crystal detectors, valve transmitters and receivers, and solid-state devices.

His vital statistics are: name—Joseph Alexander Faithful; born—April 11, 1898, in Shillong, India; callsigns—VU1AA, VS8AA, VU2BX, VU7AA, MP4BAF, and VU2JA; qualifications—PMG certificate—First Class for spark transmitter up to 5 kW (1920).

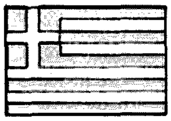
His awards and certificates:

1. The Old Old-Timers Club.
2. The Incorporated Radio Society of Great Britain, Corporate Member (1932) VU1AA.
3. The Incorporated Radio Society of Great Britain, WBE (1935) VU2BX.
4. All Asian DX Contest, 1940.
5. The Old Old-Timers Club, world's first OOTC 200 Award.
6. ARRL Old-Timers Club, 1958.
7. A-1 Operator's Club, 1961.
8. ARRL DX Century Club, 1962.
9. WAC/YL Young Ladies Radio League, 1966.
10. The OOTC QSO Party, first place in the continent of Asia (VU2JA, 1969).
11. WAS-CW, 1975.

On his way to England from India in 1914 (16 years old), he was taken as a prisoner of war during World War I. He escaped from the German POW camp in 1919 and reached England.

Can you beat this record?

At the young age of 85, Joe Faithful still feels like climbing up on the roof to experiment with different antennas—also, you can see the array of equipment still functioning faithfully. Joe is regular and active on all HF bands 80 through 10 meters between 0130 GMT to 1530 GMT depending on band condition. You can reach him at the following address if you want a direct sked or communication: J. A. Faithful, "Mon Desir," 20, Cubbon Road, Bangalore 560 001, India.



GREECE

Manos Darkadakis SV1IW
Box 3751
Athens, Greece

After a short review of Greek amateur radio history in my July column, we are now going to talk a little about the amateur community itself.

Today, the Amateur Radio Association of Greece has about 1,000 members, of course, not all of them are licensed to transmit. Licensed members number about 500. This number increases at the rate of at least 50 amateurs annually, after the two examination periods in March and September.

Not too long ago, Greece changed the callsign system that was in use for many years, which had only the number 1 after the SV prefix. We adopted the multi-number system common to most countries around the world. Therefore, Greece was divided into nine regions, and the SV0 prefix was assigned to foreigners operating

for more than one year in our country. The SV1 prefix was given to the central part of Greece including Athens, SV2 was given to Macedonia in the northern part of Greece (including Thessaloniki), SV3 was given to Peloponnissos, SV4 to Thessalia, SV5 to Dodecanese islands including Rhodes, SV6 to Hepiros, SV7 to Thraki, SV8 to all Greek islands except Dodecanese and Crete, and the SV9 prefix was given to the island of Crete.

Subsequently, another problem came in sight with the increase of amateur population in other areas besides SV1. Local problems appeared more and more frequently and, with headquarters offices in Athens, it was almost impossible to solve them either by phone or mail. Then, during a meeting between the headquarters officials and representatives of the SV2 area, the first branch office was born in 1979. After three years of satisfactory operation of the SV2 branch office, the SV9 branch office was established in 1982.

So now there are two branch offices, with more to come in the near future.

The headquarters of RAAG are situated on the top floor of a six-story building in downtown Athens (31, Arcadias and Messogion Ave., Tel.: 01/7700835). Headquarters are open every evening from Monday to Friday, 5:00-8:00 pm. RAAG's officials welcome any foreign ham to stop by and meet the SV fellow amateurs who gather every Wednesday afternoon from 6:00-9:00 pm.

So that's all for now. Next time we'll talk about interests of Greek hams in amateur radio bands, repeater sites, equipment used, etc.

ISRAEL

Ron Gang 4Z4MK
Kibbutz Urim
Negev Mobile Post Office 85530
Israel

This month I'd like to report on recent and upcoming events and activities here. These happenings give a picture of the life of the amateur radio community in Israel, how hams get together, and how they interact with the public at large.

Heralding in the spring was the Mount Gilboa March. "Marches" or, more properly, group hikes, are a popular event here, where sometimes thousands of people of all ages walk along certain routes. The annual march on Mount Gilboa, overlooking the Jordan and Jezreel Valleys, is sponsored by the Jezreel Regional Council at a time when the winter rains have finished and the Gilboa is speckled by abundant colorful wild flowers.

On our weekly Saturday morning roundtable and news magazine on 7.050 MHz, Moshe 4X4MJ, of Kibbutz Geva in the Jezreel Valley, suggested that for the first time hams take part in the march. The amateurs were enthusiastic, and Moshe initiated contacts between the Israel Amateur Radio Club's Special Events Committee and the organizers of the march.

Tee shirts displaying the IARC emblem were ordered and made available at half price to participating hams, who also were exempted from the entrance fee. The night before the event, a party of amateurs camped out on the Gilboa and established a base station. On the day of the march, tee-shirted amateurs were all along the route toting their two-meter hand-helds to provide emergency communications. Fortunately, outside of a few children separated from their parents, there were no real emergencies.

At the finish line, the base station, operating on the HF bands as well as VHF, proved the fact that hams are more than a group of people running around with "Motorolas" (Hebrew for handie-talkie)! As a result of the amateur participation, a few scores of impressed hikers requested information about ham radio.

In early April, on "National Communications Day" in the State of the Children Exhibit at the Tel Aviv exhibition grounds, amateurs were on hand operating a station with the special callsign 4X0ARI, under the capable supervision of Naomi 4X6DW. This also served as a drawing card to bring new recruits to the radio clubs. Incidentally, an interesting sidelight to this day was a few truckloads of government surplus "junk" being brought in to be disassembled by the kids who were told beforehand to bring along side-cutters and screwdrivers!

Israel Independence Day is marked by the very popular Annual Spring Contest. This is a national mini-contest taking place on 160, 80, 40, 2 meters, and 70 centimeters for the duration of three hours. Considering that there were perhaps no more than 80 stations active on the bands, this was definitely enough time to make the contest short and sweet, with little time needed afterwards to take care of logs.

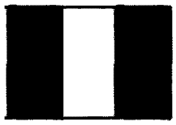
Special recognition should go to Seth 4X6DX and Ronen 4X6II, two high schoolers who set themselves up on "Radar Hill" in the Jerusalem mountains, braving unseasonably cold winds and rains (the contest was on April 18), churning out QSOs with most of the country's eighteen contest zones, modes, and bands. (In this test, the outside world counts as one zone—no doubt the biggest zone in any ham radio competition!) Stations operating in remote areas or on emergency power get special multipliers.

There was some discontent about VHF contacts being scored the same way as those on HF, as since there was no special tropospheric skip, more remote VHF operators were at a clear disadvantage. However, I'm sure that next year's contest committee will rectify the matter. All in all, it was an enjoyable event and, for me, not having the time, patience, or nerves for weekend-long contests, was just my style. Long live mini-contests!

By the time you read this, the annual Assembly of the Israel Amateur Radio Club will have come and gone. This year it was held in June at the Wise Auditorium of the Hebrew University in Jerusalem. The Assembly is a crammed evening containing a technical lecture, a "political" forum where anyone can take the floor, the election of officers of the IARC for the year, a raffle of "junk" and door prizes, and, most important, a chance to eyeball hams from all over the country whom you've been QSOing all year long. QSLs from the bureau are distributed, and people bring the outgoing bureau manager many good kilos of sorting!

Last year, when the Assembly was held in Tel Aviv, about 800 amateurs and visitors were present. There's been a feeling among club officials that because of the shortage of time and impatience of the amateurs to get the discussions and elections over with and on to the more important raffle, not enough attention is devoted to the running of our national organization. Perhaps it is indeed time to change the format and make it a day-long hamfest/convention, as the Israeli amateur population has certainly grown since the club was founded in the early fifties. In a future column, I'll report on the Jerusalem Annual Assembly and ensuing developments.

That's it for now. Conditions between the States and Israel are at present most stable on 20 meters between 2100 and 0500 GMT, so might see you there! In the meantime, happy hamming and good DXing. Shalom and 73.



ITALY

Mario Ambrosi I2MQP
Via Stradella, 13
21029 Milano, Italy

Having recently been named the Award and Contest Manager for the Italian Amateur Association (ARI), I will take this opportunity to give some rules of the Italian awards.

COM—Certificate del Mediterraneo (Mediterranean Certificate). It is issued to any amateur who can show confirmation of a two-way contact since June 1, 1952, with a fixed amateur station in at least 22 countries on the list (below) and at least 30 amateur stations of peninsular Italy. The same station can be worked only once. The certificate is available in two classes: phone and CW, and phone only. Also available for the SWL. The minimum reports allowed are RST 338 and RS 33.

Following is the list of countries:

Spain, Balearic Islands, Morocco, France, Algeria, Corsica, Sardinia, Sicily, Lebanon, Egypt, Greece, Crete, Dodecanese Islands, Turkey, Syria, Yugoslavia, Albania, Malta, Gibraltar, Cyprus, Monaco, Tunisia, Israel, and Libya, plus the deleted countries of Spanish Morocco, French Morocco, and Trieste.

WAIP—Worked All Italian Provinces. This award is issued to those amateurs who can show confirmation of a two-way contact (since January 1, 1949) with a fixed amateur station in at least 80 provinces (the equivalent of US counties) of the Italian Republic. The same station may be worked twice or more if he is in different provinces. Also available for the SWL. The minimum reports are RST 338 and RS 33. List of the Italian provinces: Agrigento Alessandria, Ancona, Aosta, Arezzo, Ascoli-Piceno, Asti, Avellino, Bari, Belluno, Benevento, Bergamo, Bologna, Bolzano, Brescia, Brindisi, Cagliari, Caltanisetta, Campobasso, Caserta, Catania, Catanzaro, Chieti, Como, Cosenza, Cremona, Cuneo, Enna, Ferrara, Firenze, Foggia, Forli, Frosinone, Genova, Gorizia, Grosseto, Imperia, Isernia, L'Aquila, Laspezia, Latina, Lecce, Livorno, Lucca, Macerata, Mantova, Massa, Matera, Messina, Milano, Modena, Napoli, Nuoro, Padova, Palermo, Parma, Pavia, Perugia, Pesaro, Pescara, Piacenza, Pisa, Pistola, Pordenone, Potenza, Ragusa, Ravenna, Reggio-Calabria, Reggio-Emilia, Rieti, Roma, Rovigo, Salerno, Sassari, Savona, Siena, Siracusa, Sondrio, Taranto, Teramo, Terni, Torino, Trapani, Trento, Treviso, Trieste, Udine, Varese, Venezia, Vercelli, Verona, Vicenza, and Viterbo.

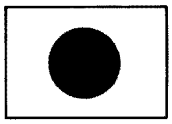
The award application has to be sent to the following address: ARI Award Manager, c/o ARI, Via Scarlatti 31, 20124 Milano, Italy, together with the complete list of QSLs, each with callsign, date, frequency, reports, time, and time of emission. Send QSLs or GCR apply. Fee: 10 IRCs or US$2.

DMG Award. Another award is a beautiful anodized-aluminum plaque with the reproduction of a photo of Guglielmo Marconi making one experimental transmission. It is available to radio amateurs worldwide. It's the OGM Award, or Diploma Guglielmo Marconi. It is not a very popular award, being a difficult one to qualify for, but it's a really beautiful plaque.

It is sent with no cost to the applicant apart from the mailing expenses (a couple of dollars). Applications have to be addressed to Roberto Borhy I4BFY, Via Toscana 133, 40141 Bologna, Italy.

To obtain the award, you have to contact and get a QSL from 40 of the following locations or 35 of the following locations plus 2 commemorative stations of Marconi, one of which must be IY4FGM. All the locations on the list are localities in which Marconi conducted his experiments. Contacts with the following locations are valid: D44 (Cape Verde), CT1 (Lisbon), CT3 (Madeira), CN8 (Morocco), EA7 (Cadice), EI (Ireland), F (France), FC (Corsica), G (London), GB (Flatholm Is.), G (Isle of Wight), GI (Ireland), GM (Scotland), HB (Switzerland), HV (Vatican), I4 (Bologna), I5 (Italy), I0 (Rome), IY4FGM, IP1TTM, IT9 (Sicily), IS0 (Sardinia), JA (Japan), LU (Buenos Aires), ON (Belgium), PY (Rio), SM (Stockholm), SM1 (Gotland), UA1 (Leningrad), VE1 (Canada), VO2 (Labrador), VO1 (Newfoundland), VK2 (Sidney), VP9 (Bermuda), W1 (Massachusetts), W2 (New York or New Jersey), W0 (Missouri), W9 (Illinois), VU (India), ZB2 (Gibraltar), YU2 (Yugoslavia), and 5A (Tripoli).

I am waiting to receive many applications! Best 73!



JAPAN

Roy Waite W9PQN
Tomigaya Grand—301
2-19-5 Tomigaya
Shibuya-Ku
Tokyo 151, Japan

RECIPROCAL AGREEMENT?

There are no reciprocal agreements with Japan, but Americans and others operate anyway.

As you know from last month's issue, Japan does not have reciprocal agreements with any country yet although a law has been passed to set things in motion. In spite of this, we have had through the years—since 1970, in fact—many non-Japanese operating ham radios in Japan. How did this come about, and why do we need a reciprocal agreement at all if "foreign" (that's you) operators can operate here anyway?

In the beginning, some time after God created the Earth, giving us light and air waves right along with all the other good things, signals coming from Japan were devoid of anything except "pure Japanese" signals. If you were assigned to Japan you might just as well pack your rig in mothballs for the duration of your stay unless, of course, you happened to come to Japan as a member of the US Armed Forces sent overseas (sometimes referred to as "Americans forced overseas"). These American military forces are given special KA callsigns and operate here quite happily just like they would in the States. The Japanese government decreed, however, that these Americans are not hams at all, and issued stern warnings to the effect that any Japanese ham having a QSO with a KA station would be punished. Following suit, the JARL will not recognize a contact with a KA station in issuing its awards. (Of course, a KA sta-

tion operating from US soil is a different matter and is fully recognized.)

So during those dark ages, what would one do if one were coming to Japan in a civilian capacity—say, to work for IBM or Gulf Oil or whatever? Well, as I said above, you would just put the rig in mothballs, take up knitting, scream and shout, commit hara-kiri, or, worse yet, join the US Army. These were the alternatives open to you, none of which was too satisfying.

In 1968, as we began to approach the end of the medieval age, the US sent a new ambassador to Japan, the Honorable Armin H. Meyer. Now, you wouldn't expect to get much more than perfunctory help from an ambassador when it comes to a ham radio problem. After all, it's only a hobby and doesn't stack up too well against the many important problems facing Japan and America. But you see, the good ambassador was himself a ham, whose call letters are W3ACE. Ambassador Meyer, setting his priorities in proper order, wanted to get on the air. Of course he could have opted for a military-type KA callsign and operated quite easily and comfortably from the ambassador's official residence, adjacent to the embassy. Or, as some people argued, under international treaty the US embassy is technically and legally US territory, and it is doubtful that the Japanese government would attempt to put the ambassador off the air should he fire up the rig and sign W3ACE/JA1.

But the ambassador wanted to do things right and decided that the time was ripe for a reciprocal agreement between Japan and the US. But it was not to be. Changes in the law to permit reciprocal licensing would have to be introduced to the Japanese Diet (Parliament), kicked around for discussion among many comittees and whatnot, presented to other ministries for approval, etc., which could take a lot of time. Furthermore, the Japanese "congressmen" were reportedly not in the mood to discuss amateur radio, a mere "schoolboy's hobby." Ambassador Meyer's assignment to Japan might indeed have expired before anything was done. (In retrospect, we can only say, "How true!") A more expeditious way had to be found. It was. Taking the cue from his callsign, W3ACE had one up his sleeve.

After many trips to the Japanese Foreign Ministry and Ministry of Telecommunications and Post (80, it was said), Ambassador Meyer was able to convince the Japanese authorities that when Japanese hams visit the United States they are permitted by law to operate an American friend's ham station as long as the American operator is in "control." This was certainly true; anyone, even a non-licensed person, may speak over the microphone of a ham station in the United States.

The Ambassador argued that since this was the case, why couldn't the Japanese allow Americans the same privilege? Furthermore, the Japanese club station structure seemed ideally suited to this type of operation. In Japan, the letter Y or Z after the numeral indicates that the station is a club station, and there are hundreds, maybe thousands of them. Almost every Japanese is a member of some club, so in addition to his own personal callsign, the Japanese ham is also allowed to use a club callsign. Therefore, the argument went, why couldn't Ambassador Meyer have a Japanese "club" station installed in the embassy, and go on the air?

The authorities agreed, and made a slight modification to the Japanese ham radio laws, specifying that citizens of the US could join a Japanese club and could operate the station as long as a licensed Japanese operator was in "control." (This word, control, caused some problems in later years since it was not defined properly in the law.)

Apparently no one noticed, however, that if a Japanese operator did have a ham friend in the United States, he could talk over the microphone and actually have QSOs but was prohibited from talking to any country with which the United States did not have a third-party agreement. None existed between Japan and America. Therefore, the Japanese ham visiting America could not talk to his Japanese buddies back in his own country. On the other hand, in Japan the government was persuaded to give out operator permits to Americans under this club system, and is still doing so today. Therefore Americans can, and do, talk to any country in the world, and third-party agreements do not enter into the picture. This was not discovered immediately, but did produce some consternation among certain circles in Japan some time later.

Anyway, W3ACE was now ready to go on the air, but he needed a call. Ambassadors have connections everywhere, so it's not surprising that in rather short order some prominent Japanese hams got together and formed a club for the exclusive use of W3ACE. The law states that not more than one third of the membership of a ham club can be non-Japanese, so to be on the safe side, the membership consisted of three Japanese hams and Ambassador Meyer. In early 1970, Ambassador Meyer finally went on the air from the American embassy in Tokyo, using callsign JH1YDR, and continued to operate until his departure in 1971.

So now the doors were open. The Japanese Radio Regulatory Bureau had a special form printed so that Americans could apply for permission to operate a club station. The form was sloppily printed, contains several grammatical errors, and parts of it are somewhat puzzling and ambiguous, but that seems to fit the pattern for government forms of any kind. It does serve the purpose, however. All that one is required to do is take the original FCC license to the US embassy, have a photocopy made, and have an embassy officer swear that it is a true copy. (Embassy officers are trained to swear.) There is even a rubber stamp made for this purpose, with a place for the officer to sign. Then this copy of the license and the aforementioned form are mailed or taken in person to a Radio Regulatory Bureau office. Turnaround time is from two weeks to a month. Permission is about the size of a postcard, and expires on the date of one's visa or ham license, whichever comes first. For renewal, one follows the same steps.

Remember that this permission is only an operator's permit and not a callsign. The two are separate in Japan, and only Japanese citizens can obtain a callsign in Japan. So one of the hitches is that you have to find a friendly Japanese ham who is either willing to let you use an existing club callsign or to form a new club for you. This can take time. If you can't find a willing Japanese ham, you are just out of luck and might as well look over the alternatives I've listed above. In practice, however, I have never heard of a case where an American could not find a Japanese ham club or Japanese ham friends to form a club. Forming a club takes a little time and money (equivalent to about $25), but is not an impossibility.

One of the problems is that the Japanese have an inspection system for any station over 10 Watts. If you are content to stay within the 10-Watt power limit (that's output power, by the way), once you find the club and put in the application you can be on the air without much delay. If you want to run higher power, you will have to wait for six months or more for the inspectors to come. There is an additional fee for the inspection.

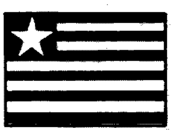
But what about the "control" of the station? Does the Japanese operator have to watch over your shoulder while you operate? Well, I can tell you that in the case of Amassador Meyer, the "control operator" definitely was not called to appear on the scene each time the rig was fired up. And, in fact, other than the first day when the station officially went on the air complete with a contingent of newspaper reporters and photographers, with the "control operator" wedged in somewhere in the crowd, Ambassador Meyer was on his own. I'm betting that that's the way he wanted it.

You may have noticed that up to this point we have limited this discussion to Americans. But what about those other countries out there? There are some others, you know. It so happened that at the same time Ambassador Meyer obtained permission to get on the air, there was (and still is) a ham in the West German embassy. Germany, this man correctly pointed out to the Japanese government, has always allowed hams from Japan (and from almost every other country, for that matter) to operate in their country. If the Americans can operate, how about the Germans? That argument brought about another modification to the law, and the Germans were then given permission to operate Japanese ham club stations just like the Americans. In more recent years, Finland and Ireland also were afforded the same privileges.

That's the story of how Americans, Germans, Finns, and Irish hams can operate from Japan even though Japan has not signed a reciprocal agreement with any country. So why do we need a reciprocal agreement? For the answer to that question, consider the following questions: What about the foreign visitor to Japan for one week? How does he find a club station or Japanese friend in such short order? Also, what if the Japanese friend who has "lent" you his club station callsign decides that he wants the call back, or what if a personal dispute arises and your Japanese sponsor decides to pull the rug out from under you? Then what do you do?

And, of course, we also have to consider the other countries. At any given time, there are any number of nationalities residing in Japan. At present, we have hams from Sweden, Italy, Great Britain, Australia, New Zealand, Canada, Philippines, and many other countries living here.

Actually, some of them are already on the air in Japan. How did they manage that since, as I have just explained, only hams from America, West Germany, Ireland, and Finland can operate here? I'll tell you about that next month. I'll also tell you about the strange situation in which certain Americans in Japan are prohibited under Japanese regulations from talking to other Americans. What complicated webs human beings weave!



LIBERIA

Mark H. Monson, M.D. EL5G
Box 1046
Monrovia, Liberia

Have you ever wondered what hamming in Liberia is like? After all, you've probably heard some EL2s on the air and maybe even worked one or two. Well, let me give you an idea of what it is like to be an amateur radio operator in Liberia.

Licenses are issued by the Liberian Telecommunications Corporation (LTC) for the Ministry of Posts and Telecommunications (P&T). LTC has authorized the Liberian Radio Amateur Association (LRAA) to administer and write the amateur examinations and recommend candidates as qualified for licensing. The president of the LRAA, Walcott Benjamin EL2BA, has appointed Lee Ruff EL2FE to write the examinations, and the president then appoints any two General-class amateurs to administer them at the site most convenient for both the examiners and the prospective amateur. A popular central location is St. Patrick's School in Monrovia, the QTH of Don Steffes EL2AL. The examinations are quite similar to those used in the US.

There are two classes of licenses, Novice and General. Novices can operate CW on any band authorized for Liberian use and phone on 2 meters. They also are allowed phone on 7.060 during the West Africa Net. They pass a simplified theory test and a 5-wpm code test, and are issued a callsign with a suffix beginning with N. Generals take a 13-wpm code test and have all privileges granted to amateurs, which include a 1-kilowatt power limit and Region 1 frequency allocations.

The Liberian government gives us no restrictions on Region 1 frequencies. We thus can operate all the usual bands that are available in the US except 6 and 1¼ meters. The P&T gave Tom Viseli EL2AV special authority to experiment and operate 6 meters, and he made many contacts which I'm sure 6-meter enthusiasts will remember.

The Region 1 bands are similar to the US bands except for the obviously larger phone bands on 20, 15, and 10 meters. It seems, however, that this will not be the case much longer. Many people forget that we have smaller overall bands on 160, 80, 40, and 2 meters. The upper limit of these smaller bands are 1.85, 7.10, 3.80, and 146.0 MHz respectively. The low bands usually require split operation for phone contacts to Region 2—which is interesting if you haven't tried it before. We now can operate 30 meters, and I made the first EL 30-meter contact with a VE3 in 1982.

Licenses are issued on an annual basis and cost $35. They expire on the 31st of December every year and a one-month grace period is then in effect. Every amateur must renew his license during the month of January, which is often a major inconvenience for those of us who live outside Monrovia.

We have between 75 and 100 licensed amateurs in the country, but of course not all of them are active. Liberia has a reciprocal licensing agreement with the US, and also offers licenses on a courtesy basis to any amateurs licensed in another country. In addition, the examinations may be given and licenses issued to non-citizens. We also are allowed to run third-party traffic with the US (but not with Canada).

Those wanting to operate from Liberia should bring their licenses with them and apply when they get here. Several photographs are required. Licenses are usually issued quickly, but a month wait is not uncommon. If the stay is short, the LRAA (Box 1477, Monrovia) can assist you if you write well in advance. Things have been a little unsettled since the 1980 coup; this resulted in two months off the air, an increase in fees, changes in the licensing

15 Windsor Dr.
Atco NJ 08004

DARC CORONA 10-METER RTTY CONTEST
1100-1700 GMT September 3

This is the third of four tests during the year sponsored by DARC to promote RTTY activity on the 10-meter band. (The 4th will be on November 6.) Each of the four tests is scored separately. Use the recommended portions of the 10-meter band.

EXCHANGE:

RST, QSO number, and name. US stations also give state.

SCORING:

Each station can be contacted only once. Each completed 2 x RTTY QSO is worth 1 point. Multipliers include the WAE and DXCC lists, each district in VE/VO and VK, plus each different US state. The final score is the total number of QSOs times the total multiplier.

AWARDS:

Awards to the leading stations in each class with a reasonable score present. Operating classes include: Class-A for single or multi-op, and Class-B for SWLs.

ENTRIES:

Official logs are recommended and are available from the contest manager (SASE or IRCs are appreciated). Logs must contain name, call, and full address of participant. Also show class, times in GMT, exchange, and final score. SWLs apply to the rules accordingly. Logs must be received within 30 days after each test. Send all entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee, West Germany.

CRAY VALLEY RADIO SOCIETY SWL CONTEST
Starts: 1800 GMT September 10
Ends: 1800 GMT September 11

Up to 18 hours of logging may be done during the contest period with a rest period clearly shown. Multi-operator stations may log during the entire contest. The contest is open to anyone in the world, and there will be two sections, phone and CW, each with two categories: single operator and multi-operator. The second category is open to two or more listeners or to clubs and more than one receiver may be used. The 1.8-, 3.5-, 7-, 14-, 21-, and 28-MHz bands may all be used.

For the purpose of this contest, the practice of logging a series of contacts made by one station is deprecated. Log entries must not include the same callsign in the station-worked column more than five times on each band.

Scores should be compiled as follows: one point for each station heard multiplied by the number of different countries heard on each band. A list of countries heard must be furnished and a separate log must be submitted for each band. Illegible logs will not be accepted.

The call areas of the USA, Canada, and Australia will each count as a separate country. All other countries will be determined by the official RSGB/ARRL Countries List. No CQ or QRZ or similar call will be allowed to count for points. If points are claimed for both sides of a QSO, the callsign of each must appear in the station-heard column.

Log sheets are available from Owen Cross G4DFI, 28 Garden Avenue, Bexleyheath, Kent DR7 4LF, England, if you include a large SAE and sufficient return postage. It is desirable that entrants use official log sheets, but entries on home-made log sheets will be accepted if the following information is given: date, time, band station heard, station being worked, report at SWL's QTH. Points may be claimed only for stations actually heard and the callsign must be shown in full.

Entries should be sent to the Contest Manager, G4DFI, at the above address, to arrive no later than October 31st. Certificates of merit will be awarded at the discretion of the board of the Cray Valley RS, and its decision will be final.

RF-CARRIER

NEWSLETTER OF THE MONTH

The Dayton Amateur Radio Association is best known for its hamvention—but this month's newsletter contest winner, the *RF-Carrier*, proves that DARA is not all show.

The *RF-Carrier* is the message-bearer for this incredibly active club. Not only do the members put on the largest amateur radio convention to be found, but they also operate three repeaters (one on 2 meters, one on 70cm, and a 440-MHz video repeater), maintain an emergency communications van with more gear than you could find in Elmer's basement, and supply people and equipment for public-service events. Not to mention a color weather radar and a local addition to the Westlink broadcast, appropriately named Dayton Link.

You might think that a newsletter editor would have his hands full keeping the members up to date on just those activities, but somehow *RF-Carrier* Editor Bob McKay N8ADA finds time for more goodies—like "Uncle Augie's Corner," a humorous feature from the Amateur Radio News Service; and "Bits and Pieces," a collection of interesting news shorts, updates on members, and general information.

And at a time when newsletter editors are scurrying helter-skelter for word processors and hard-to-read dot-matrix printers, the *RF-Carrier* is still typed—uncompressed, large type that is easy on the eyes.

It may not be the easy way to prepare a newsletter, but it is evident that, to McKay and the members of DARA, the best quality is worth the extra effort.

If you would like to enter your newsletter in *73*'s contest, put us on your mailing list. Send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

IARS/CHC INTERNATIONAL CONTEST
CW
Starts: 0000 GMT September 10
Ends: 2400 GMT September 11
SSB
Starts: 0000 GMT September 17
Ends: 2400 GMT September 18

This is a semi-annual contest sponsored by the International Amateur Radio Society and Certificate Hunters Club. Work stations once per band; no repeaters or crossmode contacts allowed. Look for stations calling "CQ CHC."

EXCHANGE:

RS(T), IARS and/or CHC number, and state, province, or country.

FREQUENCIES:

CW—70 kHz from the bottom of the band.

SSB—3960, 7260, 14300, 21360, 28600.

SCORING:

Multiply QSOs times the number of countries worked, times the number of IARS/CHC members worked. Any member of both divisions counts as two multipliers!

AWARDS:

Engraved plaque to the highest overall score. Certificates awarded to the highest scorer per band and to the top 10 runners up.

ENTRIES:

Logs must show date and time in GMT, station worked, exchanges sent and received, QSO points claimed, and final claimed score. All entries with 100 or more QSOs must also include a check sheet. Entries must be mailed by December 1st to Ted Melinosky K1BV, 525 Foster St, South Windsor CT 06074. Include a large SASE for a copy of the results.

WASHINGTON STATE QSO PARTY
0100 to 0700 GMT September 17
1300 GMT September 17 to 0700 GMT September 18
1300 GMT September 18 to 0100 GMT September 19

The eighteenth annual contest sponsored by the Boeing Employees' Amateur Radio Society (BEARS) is divided into 3 operating periods as show. All amateurs are invited to participate. All bands (except 10.10 to 10.15 MHz) and modes may be used, but no CW QSOs are allowed in the phone bands. Stations may be worked once on each band and mode for contact points and more than once each band/mode if they are additional multipliers.

EXCHANGE:

QSO number, RS(T), and state, province, country, or Washington county.

FREQUENCIES:

Phone—1815, 3925, 7260, 14280, 21380, 28580.

CW—1805, 3560, 7060, 14060, 21060, 28160.

Novice—3725, 7125, 21150, 28160.

SCORING:

Washington stations score 2 points for each phone contact and 3 points for each CW contact, including contacts with other Washington stations. Multiply QSO points by the total number of different states, Canadian provinces, and other foreign countries worked.

All others score 2 points for each phone contact and 3 points for each CW contact with a Washington station. Multiply QSO points by the total number of different

Washington counties worked (39 maximum). There will be an extra multiplier of one for each group of 8 contacts with the same Washington county for all non-Washington stations.

AWARDS:

Certificates will be awarded to the highest-scoring station (both single and multi-operator) in each state, Canadian province, foreign country, and Washington county. Additional certificates may be issued at the discretion of the contest committee. Worked Five BEARS Awards are also available to anyone working 5 club members before, during, or after the QSO Party, unless previously issued. (All QSO Party entries will be screened by the contest committee for possible Worked Five BEARS Awards.) Worked Three BEAR Cubs Awards are also available for working 3 Novice members. All BEARS awards besides QSO Party certificates are handled by Doyel Burleson WA7HKD, Award Chairman. (See *73* for August, 1979, page 28, for additional details.)

ENTRIES:

Logs must show dates/times in GMT, stations worked, exchanges sent and received, bands and modes used, and scores claimed. Include a dupe sheet for entries with more than 200 QSOs. Each entry must include a signed statement that the decision of the contest committee will be accepted as final. No logs can be returned. Results of the QSO Party will be mailed to all entrants and an SASE is NOT required. Log sheets and summary sheets must be postmarked no later than October 19 and sent to: Boeing Employees' Amateur Radio Society, c/o Willis D. Propst K7RS, 18415 38th Avenue South, Seattle WA 98188.

KANSAS STATE QSO PARTY

0100 to 0700 GMT September 17
1300 GMT September 17 to 0700 GMT September 18
1300 GMT September 18 to 0100 GMT September 19

This is the second annual contest sponsored by the Boeing Employees' Amateur Radio Society of Wichita (BEARS0) and all amateurs are invited to participate. Use all bands (except 10 MHz) and modes. Stations may be worked once on each band and each mode for contact points, more than once each band/mode if they are additional multipliers.

EXCHANGE:

QSO number; RS(T); and state, Canadian province, foreign country, or Kansas county.

FREQUENCIES:

Phone—1815, 3925, 7260, 14280, 21380, 28580.
CW—1805, 3560, 7060, 14060, 21060, 28160.
Novice—3725, 7125, 21150, 28160.

SCORING:

Kansas stations score two points for each phone contact and three points for each CW contact, including contacts with other Kansas stations. Multiply contact points by the total number of different states, Canadian provinces, and other foreign countries worked. All others score two points for each phone contact and three points for each CW contact with a Kansas station. Multiply contact points by the total number of different Kansas counties worked (105 maximum). For all stations multipliers are counted only ONCE regardless of how many bands or modes they are worked on. However, there will be an additional multiplier of one for each group of eight contacts with the same Kansas county for all non-Kansas stations.

AWARDS:

Certificates will be awarded to the highest scoring station (both single and multi-operator) in each state, Canadian province, foreign country and Kansas county. Additional certificates may be awarded at the discretion of the contest committee.

Worked Five Kansas BEARS Awards are also available to anyone working five club members before, during, or after the QSO Party. All QSO Party entries will be screened by the contest committee for possible Worked Five Kansas BEARS Awards. All Kansas BEARS awards are administrated by Mike Thornton WA8TAH, Contest Chairman.

ENTRIES:

Logs must show dates and times in GMT, stations worked, exchanges sent and received, bands and modes used, and scores claimed. Include a dupe sheet for entries with more than 200 QSOs. Each entry must include a signed statement that the decision of the contest committee will be accepted as final. No logs can be returned. Log and summary sheets are available for an SASE from the contest chairman. Entries must be postmarked no later than October 20 and sent to: Boeing Employees' Amateur Radio Society of Wichita, c/o Mike Thornton WA0TAH, 1001 Munnell Ave., Wichita KS 67213.

* = QRP No multipliers.

non-Scandinavian amateurs to work each other and to promote communications skills between amateur stations worldwide. For the purpose of this, the 25th running of this annual event, non-Scandinavian stations will try to work as many Scandinavian stations as possible. Scandinavian stations are defined by the following prefixes: LA/LB/LG/LJ (Norway), JW (Svalbard and Bear Islands), JX (Jan Mayen), OF/OG/OH/OI (Finland), OHØ (Aland Island), OJØ (Market Reef), OX (Greenland), OY (Faeroe Island), OZ (Denmark), SJ/SK/SL/SM (Sweden), and TF (Iceland).

Operating categories include:

(a) Single Op/Single Xmtr—allband only; one person performs all operating, logging, and spotting functions. The use of multiplier spotting assistance or any other form of alerting assistance is not allowed in this category.

(b) Multi-Op/Single Xmtr—allband only; only one signal allowed at any one time on any band. The station must remain on the band for at least 10 minutes following initial transmission on that band after band change.

(c) Multi-Op/Multi-Xmtr—no limit to transmitters, but only one signal per band is allowed.

Club stations may work only multi/single or multi/multi categories. All transmitters and all receivers, including spotting equipment for a station using one and the same callsign must be located within a 500-meter radius. The same station may be worked once on each band. Only CW-to-CW and phone-to-phone QSOs are valid; no cross-mode contacts.

EXCHANGE:

RS(T) plus serial QSO number starting from 001. QSOs after 999 are numbered 1000, 1001, etc. Multi-op/Multi-Xmtr stations use separate serial numbers, starting from 001 on each band.

FREQUENCIES:

CW—3505-3575, 7005-7040, 14010-14075, 21010-21120, 28010-28125.

Phone—3600-3650, 3700-3790, 7050-7100, 14150-14300, 21200-21350, 28400-28700.

Don't forget to use only those frequencies you are authorized to use. (Above frequencies for the phone segment list non-US frequencies!) Regions 2 and 3 stations may also transmit on their frequencies above 3790 and 7100.

SCORING:

European stations count one point for every complete Scandinavian QSO on any band. Non-European stations count one point per Scandinavian QSO on 20- through 10-meter bands and three points per QSO on 80 or 40 meters.

The multiplier is the number of Scandinavian call areas worked. Note that LA1 = LS1 = LJ1! Portable stations without a district number count for the tenth area, e.g., W4XXX/OZ counts for OZØ and G3XYZ/LA counts for LAØ. OHØ and OJØ are separate call areas. SJ9 counts for the 9th call area in Sweden. Each multiplier cannot be credited more than once per band. The final score is the total QSO points times the sum of all multipliers.

AWARDS:

Top scorer in each country as well as each US call district, in each category, both on CW and phone, will receive a contest award provided a reasonable score is made. Depending on the number of entrants from each country, the award of additional certificates will be considered by the contest committee. The top scoring single-operator stations on each continent will receive a contest plaque both on CW and phone, provided a reasonable score is made.

ENTRIES:

Signed original logs (or copies of original logs) must be submitted separately for CW and phone. Logs to be filled out in the following order: date and time in GMT, station worked, sent and received exchange, band, multipliers, and points.

All entrants must submit a summary sheet showing station callsign, category, name of operator(s) and address. Indicate number of QSOs per band less duplicates, number of duplicates per band, number of multipliers per band, QSO points per band, and final score.

All entrants must submit a multiplier sheet for each band with more than 200 QSOs. Possible duplicate QSOs must be shown in the log and counted for zero points. Each entrant shall submit a duplicate QSO sheet for each band with more than 200 QSOs. Duplicate sheet to contain worked stations listed by DXCC countries and call areas.

Logs and accompanying sheets shall be mailed no later than October 30, 1983, addressed to: SAC Contest Committee, PO Box 306, SF-00101 Helsinki 10, Finland.

Violation of amateur radio regulations applicable in the country of the contestant or of the rules of this contest, unsportsmanlike conduct, and the taking of credit for unverifiable QSOs or multipliers may lead to disqualification. A log showing more than 1% unremoved duplicate QSOs results in unconditional disqualification. Each unremoved duplicate QSO found by the contest committee results in a penalty of 5 QSOs of the same value as the duplicate.

By submitting a contest log, the entrant agrees to abide by the rules of the Scandinavian Activity contest and by the decisions of the contest committee. The committee's decisions are final and definite. Right to changes in the rules is reserved.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. GEMINI 10 .... $325

Ampersand
electronics
6065 Mission Gorge Rd. #66
San Diego, CA 92120

October 1, 1983, beginning at 7:30 am, rain or shine, at the Warrington Motor Lodge, Route 611, Warrington PA. Advance registration is $4.00 and includes admission to the 12th annual Pack Rats Hamarama on Sunday, October 2, 1963, at the Bucks County Drive-In Theater, Route 611, Warrington PA. Admission to the flea market is $3.00 and selling spaces are $5.00 each (bring your own table). For advance registration, phone Lee A. Cohen K3MXM at (215)-635-4942, or send a check to Hamarama '83, PO Sox 311, Southampton PA 18966.

CEDAR RAPIDS IA
OCT 2

The Cedar Valley Amateur Radio Club (W0GO) will hold its 9th annual ARRL CVARC Hamfest on Sunday, October 2, 1983, beginning at 7:00 am, at the Hawkeye Downs Exhibition Building, Cedar Rapids IA. Tickets are $2.00 in advance and $3.00 at the door. Tables are $5.00 for the first and $7.00 for others. There is an overnight camping area, picnic facilities, ample parking, and a concession stand. There will be movies, manufacturers, dealers, and ARRL representatives featured. Talk-in on 146.16/.76, .52, and 223.34/.94 MHz. For advance tickets or reservations, write CVARC Hamfest, PO Box 994, Cedar Rapids IA 52406.

YONKERS NY
OCT 2

The Yonkers Amateur Radio Club will sponsor the Yonkers Electronics Fair and Giant Flea Market on Sunday, October 2, 1983, from 9:00 am to 4:00 pm, rain or shine, at the Yonkers Municipal Parking Garage, corner of Nepperhan Avenue and New Main Street, Yonkers NY. Admission is $2.00 each and children under 12 will be admitted free. Gates will be open to sellers at 8:00 am and there will be a $6.00 admission per parking space which will also admit one (bring your own tables). Refreshments, free parking, and sanitary facilities will be available, as well as unlimited free coffee. There will be live demonstrations all day and a giant auction at 2:00 pm. Talk-in on 146.265T/146.865R or .52 direct. For more information, write YARC, 53 Hayward Street, Yonkers NY 10704, or phone (914)-969-1053.

REVERE MA
OCT 16

The 19-79 Amateur Radio Association of Chelsea MA will hold its annual fall flea market on Sunday, October 16, 1983, from 11:00 am to 4:00 pm (sellers admitted at 10:00 am), at the Beachmont VFW Post, 150 Bennington Street, Revere MA. Admission is $8.00 at the door, if available. Talk-in on .19/.79 and .52. For table reservations, send a check to 19-79 Amateur Radio Association, PO Box 171, Chelsea MA 02150.

BALTIMORE MD
OCT 23

The Columbia Amateur Radio Association will hold its 7th annual hamfest on Sunday, October 23, 1983, from 8:00 am to 3:30 pm, at the Howard County Fairgrounds, 15 miles west of Baltimore MD, just off I-70 on Rte. 144, 1 mile west of Rte. 32. Admission is $3.00. Indoor tailgating is $3.00 additional. Food will be available. Talk-in on 147.735/.135 and 146.52/.52. For table reservations and more information, write Ed Wallace K3EF, 9905 Carillon Drive, Ellicott City MD 21043.

PHASE IIIB

Recovering from a troubled beginning, Phase IIIB—now AMSAT/OSCAR 10—was boosted into a higher orbit on Monday, July 11. After correcting OSCAR 10's attitude and increasing the exposure of the solar cells, ground stations fired the kick motor for the first time at 2232 UTC. The second firing, which was scheduled for July 20, was to alter the inclination of the satellite. OSCAR 10 planners hoped to have the transponders operational by July 24.

OSCAR 10's transponders operate in two frequency ranges. The general beacon for Mode B is on 145.810 MHz, and the engineering beacon is slightly higher, at 145.987 MHz. The uplink is between 435.025 and 435.175 MHz, and the downlink is between 145.975 and 145.825 MHz. The general beacon for Mode L is on 436.020 MHz, and the engineering beacon is at 436.040 MHz. The Model L uplink is from 1289.050 to 1269.850, with the downlink between 436.950 and 436.150 MHz.

HAM HELP

I need the technical manual for an Eico model 460 oscilloscope. I will copy and return it.

H. L. Church
309 W. St. Louis St.
Lebanon IL 62254-0126

Can anyone supply me with a schematic and operating manual for the Akai VTS-150 color camera and recorder? I will pay copying costs or return the original. I could use similar data on the Morrow MB-6 receiver and the MB-565 transmitter.

Mark R. Nelson AJ2X
4317 Foley Drive
Knoxville TN 37918

CORRECTIONS

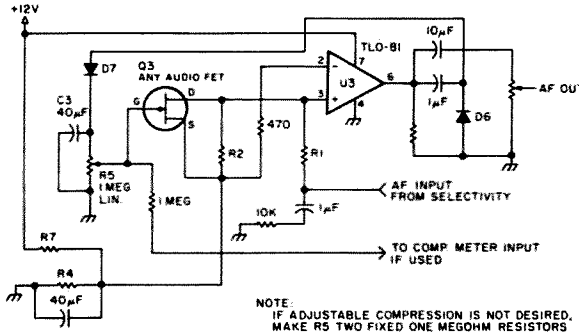

Fig. 1. Compression circuit with adjustable compression modification.

A couple of errors appeared in "What? Another Audio Filter Project?" in the November, 1982, issue of *73*. The compression and power schematic on page 33 was incorrectly drawn; it should look like Fig. 1. Fig. 1 also incorporates an adjustable compression modification. The modification described in the article will not work.

The clipper circuit on page 33 needs different component values to produce a clean output. Fig. 2 shows the circuit and new component values.

In some cases, the unit proved to be rf-susceptible. The cure is to run all of the leads from the filter through ferrite beads as they enter the case, and bypass the lead to ground with small ceramic capacitors.

George Thurston W4MLE
Tallahassee FL

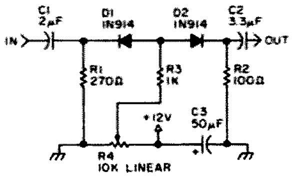

Fig. 2. Clipper circuit and new component values.

On page 12 of the July, 1983, issue, the author of "You Can Build This Code Trainer" was inadvertently omitted. The author of the article is Harry Latterman K7ZOV, 1655 W. Lindner Ave., Mesa AZ 85202.

Avery L. Jenkins WB8JLG
73 Staff

There is a way to improve the accuracy of the "VUM: Volume Units Meter," which appeared on page 72 of the August, 1982, issue. With the given values of R1-R7, the input attenuator has an error of about 10 percent. The following values will give an error of less than 1 percent: R1—6,900; R2—15k; R3—47k; R4—150k; R5—470k; R6—1.5M; and R7—4.7M.

REVIEW

SUPER-RATT RTTY/CW PROGRAM WITH RBBS

Surely you have heard the saying "Build a better mousetrap and the world will beat a path to your door." Why not turn things around and build a better "Ratt"? That's what the folks at Universal Software have done. First impressions are only worth so much, but if my judgment is correct, the world of Apple-computer-owning hams is already beating a path to the door of the maker of Super-Ratt. A software-only package, Super-Ratt is meant to be used with a 48K Apple II, Applesoft Basic, and at least one DOS 3.3 disk drive. You also need a terminal unit, one capable of interfacing to the Apple's TTL-compatible game I/O connector.

Though this review deals only with the straightforward RTTY portion of the program, Super-Ratt also offers CW transmit and receive capability and an integrated radio bulletin board (RBBS). The program itself comes on a non-protected DOS 3.3 disk and is accompanied by a professional-looking 65-page manual.

Set aside a couple of hours to get Super-Ratt running. First you'll need to make a working copy of the diskette and perhaps add some canned messages. And you will have to interface your Apple to demodulator and modulator circuits. Just about any of the popular terminal units (TU) should do the job, provided that it is TTL-compatible. Do take care to avoid hooking anything that remotely resembles high voltage to your computer, unless you want to make some repairs. For this review, a slightly modified Flesher TU-170 was used. If you don't have a TU, then you might want to build one of the simple circuits shown in the back of the Super-Ratt manual. A third choice is the Radcom TU which plugs directly into one of the Apple's peripheral slots.

Once the set-up phase is complete, actual operation starts simply: Just insert the disk, turn on the computer, and tune in a signal. There are no menus to deal with; the program goes directly to the receive mode and its standard five-part, 24-line screen display. The top and bottom lines are devoted to prompts and status information such as the mode, speed, and buffer. The received-text area is composed of 13 forty-character lines, while the transmit type-ahead buffer contents are displayed with four lines. Another four lines are used to denote boundaries, and the final line, situated between the receive and transmit display regions, is a scrolling readout of what is being sent during transmit. For tuning purposes, there is a mark/space indicator on the top status line.

Typing a combination of the control shift and P keys stops the receive function and brings up the help screen. There are 27 control codes, some of which you may use numerous times in each QSO; others you may never touch. "Joe Ham" will probably find the following most useful: Control-I inverts the mark/space sense; Control-K is for CW identification; Control-X, when put at the end of the transmit buffer, automatically switches the system back to receive; and Control-T is used for "break-in" operation for times when you want to make a quick reply and not disturb the type-ahead buffer. Other commands switch the speed or mode (Baudot, ASCII, and Morse) and let the operator erase the transmit or receive buffer contents.

The commands mentioned so far give an operator as many or more features than were usually found in an old-time mechanical RTTY station. The remaining 20+ Super-Ratt commands are like the icing on the cake. Among other things, they permit you to use an almost full screen for receiving, load and save disk files, have the buffer contents automatically stored to disk, make entries in a disk-based logbook, define and then use up to eleven different temporary sequences (i.e., the other op's callsign), and relay the last received transmission.

Besides straightforward CW and RTTY operation, Super-Ratt offers RBBS, selcal, and shortwave-listening capability. The following is just a brief introduction to these modes:

• RBBS (Radio Bulletin Board System) "... allows other people to use your computer as a message center. You do not need to actually operate your station yourself. The Apple II will do all the work." (From the Super-Ratt manual.) A quick spin across the RTTY portion of 40 or 80 meters will demonstrate the popularity of radio bulletin boards. If you decide to become a "sysop" (owner and operator of an RBBS), then be prepared to dedicate a rig, antenna, and computer to the project plus be willing to maintain the user-generated files frequently. Note: Be sure to check the FCC rules concerning unattended operation.

The Super-Ratt RBBS software has several unique features. Users can call up to four analog readouts that are based on inputs to the Apple game port, turn on a tape recorder and leave a voice message (VHF bands only), and switch the system to other codes and speeds.

• Selcal, or selective calling, puts Super-Ratt on guard for a password. As soon as it is received, the computer beeps and displays the time.

• SWL or shortwave listening: If you tire of the ham bands, then try tuning across the commercial spectrum. You'll find plenty of RTTY signals, some of which are unencoded. Super-Ratt makes copying these easier by offering a continuous range of speeds and automatic storage.

If you are like me and operating takes a backseat to hardware and software tinkering, then you'll be happy to learn that Super-Ratt is meant for the hacker. The programs are written in Applesoft Basic and come in both remarked and compacted versions. This brings us to "Ratt-Soft," an offshoot of Basic that uses the Apple's ampersand (&) command that allows users to define their own functions. Super-Ratt uses almost three dozen ampersand functions, and the manual includes a short description of each one in case you want to write your own software or make changes in the original program. The author of Super-Ratt encourages you to strike out on your own and, accordingly, the manual gives a brief description of the program variable names, reset parameters, and I/O locations. Obviously, anyone who wants to make use of this information should be acquainted with Basic programming and the Apple computer first.

Even the best mousetrap has some non-distinguishing characteristics, as does Super-Ratt. This program, like other software-only RTTY packages, is only as good as your terminal unit and receiver. (The Egbert II RTTY program is a notable exception. There, the software and computer form the TU.) If you have a simple one-chip pnase-locked-loop demodulator, then you are going to have trouble when fading and noise move in. Other quirks include the cumbersome way in which the time can be accessed if you have a hardware clock in your Apple; the program requires a manual update command to be typed on every occasion the time is sent, and if you are one of those operators who likes to monitor the status of the transmit and receive buffers, you'll find that the information is available but at the expense of shifting out of receive to glance at it. Finally, the mark/space status indicator is no substitute for a scope display or a good meter indicator when it comes time to tune in a signal.

My most serious reservations about Super-Ratt are the result of its sophistication. As a beginning user, at times I found myself typing the wrong command keys. The result certainly isn't fatal but it can be embarrassing. Hams new to RTTY may be intimidated by the array of commands, and the instructions don't always help — they highlight rather than fully explain features. Similarly, if you are a new Apple owner, it might be a good idea to spend a few weeks trying other, less sophisticated operations with your computer before you start interfacing it to a terminal unit and creating a RTTY program disk.

There are a handful of RTTY programs sold for the Apple computer. What makes Super-Ratt special? One, it offers solid performance for day-to-day operating; two, the radio bulletin board system is as interesting and popular as they come; and three, Super-Ratt is a program you can tinker with and grow into. Universal Software has indeed built a better "Ratt." And I suspect that the well-beaten path to their door will soon be turning into a highway.

Super-Ratt sells for $59.95. For more information, contact *Universal Software, 9 Shields Lane, Ridgefield CT 06877*. Reader Service number 490.

DRAKE 9000E COMMUNICATIONS TERMINAL

Within the past two to three years, after a rather lethargic period, there has been a resurgence of interest in amateur and SWL RTTY activity. Primarily, this has been due to the state of the art moving rapidly forward, thus making available video-display-type communications terminals, which, technically at least, far surpass the capabilities of teleprinters and their associated equipment.

This revival has also had the incentive of lowered costs of such terminals, together with the popularity of personal computers that has burst upon us within the last few years. Even the most lowly $89 computer can now transmit and receive RTTY and CW. Electronics has never been a standstill industry, and with the advent of the integrated circuit, it was only a matter of time until computers and ham radio merged to form a single path of two extremely exciting interests.

Actively aiding this explosion of interest in communications, the Drake Company of Miamisburg, Ohio, has recently released the Theta 9000E communications terminal.

To say that this terminal is the ultimate terminal would be incorrect, not because of any lack of features, by any means, but because of the very volatility of electronics design. Nevertheless, the Drake 9000E has so many operating features that some owners will probably never get around to using all of them. Let's look at these capabilities in depth and see how useful they can be to the operator or listener.

Features

The Theta 9000E operates in five distinct modes and numerous sub-modes. Not all of these are related directly to amateur radio or commercial monitoring, for several of these are definitely computer-oriented. This is not to say that this aspect may not also be ultimately used for ham operation. In fact, as FCC regulations permit (and it may be hoped these will continue to be brought to within the state of the art), the 9000E will be extremely useful when used in computer-to-computer communication.

Specifications of the 9000E are shown in Table 1. As a communications terminal, the 9000E will send and receive CW, Baudot (RTTY), and ASCII (RTTY and KCS). The last-named, Kansas City Standard, has some restrictions, which will be mentioned later. As a computer, the 9000E has a full word-processor function, useful for writing articles, letters, etc.

A standard and an enlarged video-display format can be used, as well as a memory capability of 14,000 characters which may be scrolled on-screen. A graphics function with an accessory light pen allows drawings to be produced on screen, which may be saved to a cassette tape recorder (not supplied) or transmitted to another Theta 9000E.

It is possible to use the terminal in full-

Drake Theta 9000E communications terminal (Photo courtesy of R. L. Drake Company).

WHAT DO *YOU* THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

duplex mode while using ASCII, and you can also use the unit as an RS-232C terminal at up to 9600 baud. Three frequency shifts are available, and either high-tone or low-tone pairs may be selected. Mark-only or space-only copy can be switched in and out, if required.

The only mandatory external equipment required for terminal operation is a power supply and a video-display monitor.

Additional features will be discussed in greater detail below.

Hardware

Mechanically, the 9000E definitely does *not* look like something kludged up in someone's garage. The appearance is first-class, and the mechanical rigidity is solid. All of the electronics are packaged in an attractively finished satin-black metal case measuring 16¼ inches by 9¾ inches, with the panel sloping from 1¾ inches at the front to 3¾ inches at the back.

The keyboard is standard "QWERTY" in ASCII format. In addition, there is a row of 14 special-purpose dual-function keys along the top of the keyboard. These are dedicated to control functions and are quickly identified as they are colored red with white markings (except one, the RESET key, which is white with black markings). There are numerous other computer-oriented keys on this keyboard, such as ESC (Escape), RETURN, BS (Back Space), etc. Nevertheless, when transmitting Baudot, it will conform to the requirements of FCC Regulations Part 97.69 regarding International Telegraphic Alphabet No. 2.

All of the alpha and numeric keys are colored light gray with white indicia, special control keys are black with white, and function keys are either white with black lettering, or, as in the case of the space bar and shift keys, red and red with white, respectively.

Overall, the keyboard has a very pleasing appearance and a good, definitive touch when the keys are depressed. I found the position of the RETURN key a little far away for my pinky to reach comfortably; it must pass over DELETE on the way. However, this opinion is subjective—nearly every computer now has the ENTER or RETURN key at a slightly different position, and it is a matter of getting used to it. (As will be explained later, there are only a few occasions when it is necessary to use the RETURN key anyway, as full-word wraparound is supported.)

It is necessary to remove the case in order to install two AA-type batteries used for memory retention (good for about one year). This is a simple operation and takes but a moment. LEDs are used to indicate power on and the presence of space and mark signals. Two variable controls, Fine Tuning and Volume, are in a vertical line on the right-hand side of the cabinet.

All connections to the 9000E are made via the rear panel (the internal speaker for the audio monitor faces out from this back panel also). Bringing all of the peripheral cabling out the back is quite satisfactory — the great number of possible connections would otherwise make a rat's nest of cabling. Coaxial cable the size of RG-174 (but not otherwise identified) is supplied for making connections to peripheral equipment, together with sufficient phono connectors. The use of this type of connector, especially for RS-232C connections, is not the best way to go. The parallel printer port has a standard DB-25 connection, which is much more effective. The power cable exits from the back panel, too, and jacks are available for connecting an external oscilloscope for monitoring space and mark tuning, if desired. All FSK and AFSK connection circuits are via high-voltage, high-current optoisolators.

The audio monitor is used for both transmitting and receiving and has its own gain control. Monitoring in Receive can be either the output of the mark signal path or space or the audio output from the agc amplifier prior to the channel filters.

Video-Display Terminal Requirements

The video-display terminal (monitor) may be of any size screen. Drake offers a monitor as an option. The display must be capable of accepting a composite video signal of 1.0 volt p-p at 75 Ohms impedance.

Power-Supply Requirements

A power source of 13.6 volts dc (−1, +2 volts) at 1.3 A is required for the 9000E. (Drake also offers a suitable power supply as an option.) An on-off rocker-type switch is on the back panel.

Functional Description (Communications-Oriented)

RTTY. The first mode to be described, and probably the most important in the eyes of many who are presently operating, is RTTY. RTTY is available on the 9000E in a multitude of modes, shifts, and speeds. Possibly the most common mode currently in use on the ham bands is Baudot operation with 170-Hz shift and 45.45 baud (60 wpm). However, all of the shift frequencies and baud rates shown in Table 1 are available by keyboard selection. Of course, all of those shown are not currently authorized by the FCC for amateur operation in the US.

These frequency shifts and transmission rates are available as AFSK or FSK transmissions, depending upon the output that is selected for use with the transmitter. Reception will be at the selected shift/speed, and, although it is possible to receive at a different shift or speed than that transmitted by using a quick keyboard change, this is a highly unlikely possibilty.

It should be noted that the shift frequencies and speeds shown in Table 1 are available in a high-tone or low-tone output. The choice made is largely dependent upon whether you are operating in the HF bands or on VHF.

ASCII. The other primary sub-mode in RTTY operation is the one that is gaining more and more adherents since being authorized by the FCC — ASCII. This mode will be of interest to computer buffs, too, as they may transmit and receive computer programs and operate remote computers with no translation needed from ASCII to Baudot.

As with Baudot, the ASCII shifts, speeds, and high-low tones are available, but because of the complete differences

1. Code
Morse code (CW), Baudot code (RTTY), and ASCII (RTTY and KCS)

2. Characters
Alphabet, figures, symbols, and special characters

3. Speed
Morse: Receiving 5-50 words/minute (automatic track)
Transmitting 5-50 words/minute (weight 1:3~1:6)
Baudot and ASCII: 45.45, 50, 56.88, 74.2, 100, 110, 150, 200, 300, 600, 1200, 2400, 4800, 9600 baud

4. Input
AF input impedance (CW, RTTY, and ASCII): 500 Ohms
KCS input impedance: 500 Ohms
TTL level input: common to CW, RTTY, and ASCII
RS-232C input: common to CW, RTTY, and ASCII

5. AF Frequency
Morse: 830 Hz

RTTY (Baudot, ASCII):	Mark	1275 Hz (low tone, 2125 Hz (high tone)
	Shift	170 Hz, 425 Hz, 850 Hz + fine tuning
KCS:	Mark	2400 Hz
	Space	1200 Hz

6. Output

Keying output:	CW	80 mA, 200 V	(optoisolator)
	FSK	80 mA, 200 V	(optoisolator)
	Remote	200 mA, 100 V	(optoisolator)
	PTT	100 mA, 100 V	(positive voltage only)

AFSK output impedance: 500 Ohms (common to CW, RTTY, and ASCII)
RS-232C output: common to CW, RTTY, ASCII

7. AFSK Output Frequency
Morse: 830 Hz

RTTY (Baudot, ASCII):	Mark	1275 Hz (low tone), 2125 Hz (high tone)
	Shift	170 Hz, 425 Hz, 850 Hz + fine tuning
KCS:	Mark	2400 Hz
	Space	1200 Hz

8. Display Output
Composite video-signal output impedance: 75 Ohms

9. Interface for Printer
Centronics compatible parallel interface

10. Number of Characters Displayed
Screen format (keyboard selectable):
80 characters × 24 lines = 1920 characters
40 characters × 24 lines = 960 characters
Possible number of characters displayed: 14,000 characters
Graphics mode: 80 elements wide × 72 elements high

11. Battery-Back-Up Memory
256 characters × 7 channels

12. Buffer Memory
3120 characters

13. Output Impedance for Oscilloscope
200k Ohms

14. AF Output
150 mW
Output impedance: 8 Ohms

15. Power Supply Requirement
Dc +12 V, 1.3 A

16. Dimensions
415mm × 245mm × 45mm~78mm

17. Accessories

Instruction manual	1
Pin plug	13
Fuse	1
Coaxial cable	4m
Light pen	1
3P connector	1

Table 1. Specifications for the Theta 9000E terminal.

in the codes of Baudot and ASCII, the 9000E has dedicated keys to permit selection upon power-up of either one or the other.

One other aspect of ASCII operation will be of interest: the so-called Kansas City Standard (KCS). This operation may be used for recording on a cassette recorder, so that in effect you have a "tape system" capable of storing text or RTTY pictures for future use.

CW. This is the third mode available for transmitting and receiving with the 9000E. This, too, is selected using a dedicated key. Similar to the Baudot and ASCII modes, the CW mode may be effected with several sub-types of operation. But in the case of CW, these probably are more valuable than in the RTTY mode. For example, you may transmit to the screen and built-in audio monitor any approved CW character. The latter is a "local" mode and is not transmitted (you could do that, too, of course). Also, if you need the practice, you may place the terminal in automatic cipher mode and it will send random five-letter group characters forever, if you would like that. You may also direct these groups to a tape recorder or a printer. Using your hand key, bug, or keyer, you can send manually and have it sound on the speaker and appear on the screen. Be-

cause of the acute character-recognition attributes of the 9000E, your sending had better be flawless or nearly so. This will be discussed again later on.

You may also send manually but receive by way of the terminal; technically, you could do the reverse by using the keyboard to transmit and listening and copying manually. You may even do this and use the keyboard for typing what you are hearing and have the screen or printer display your copy.

CW transmitting speeds are pre-selected, with the initial power-up state being 11 wpm. Nine other speeds may be keyboard-selected: 5, 6, 8, 14, 18, 23, 30, 39, and 50 wpm. Ten steps of weighting may be set, also by keyboard control.

CW reception speeds are automatically tracked. If there is a sudden switch from a higher speed of reception to a lower one, several characters may be dropped until synchronization is achieved.

The speeds shown above are not a fixed factor. A refinement of 1/64th higher or lower than the existing speed is possible by a double-key entry. (Using the 9000E for code practice, you could select a goal of speeding up 1/64th each day.)

Description
(Computer-Oriented)

If the preceding modes could be described as "communications," then the next can be called "computer." Nevertheless, these, too, may be used in communications where authorized or by direct wire using a modem.

Word Processor. The word-processor mode operates just as any computer word-processing program would, but it does not have all of the embellishments of some of the more esoteric computer programs or dedicated word-processing terminals. Notwithstanding that statement, it is still quite adequate for letter-writing, small article preparation, lists, logging, etc.

For those hams who may not be familiar with computer operations, word processing is the ability to compose, write (type), delete, modify, and move characters, sentences, and blocks of words on the video display until the material is satisfactorily composed. This is like typing something and then being able to change or correct any of it *before* committing it to the printed page.

The word-processor mode is accessed by pressing two keys simultaneously. The baud rate will be 300, and the AFSK output will be 2400 Hz mark and 1200 Hz space (KCS). Up to three pages of 65 lines are available for preparation purposes, with the video presenting 24 lines of 80 characters. The screen splits vertically in this mode, with the leftmost eight character columns comprising an "operation" area and the next 72 columns allowed for "data" — in this case, this is your text area.

In the word-processing mode, you may connect to a tape recorder as well as a printer. Full cursor control is obtained by using the labeled arrow keys, and the cursor may be moved up to 99 lines in one move (depending upon its location at the moment) by three keystrokes.

A great many other standard word-processing functions are available using similar key motions, such as block text change, line insertion/deletion, left and right margin justification, insert and delete spaces, and numerous others. Even one of the more useful and highly desirable functions found in good commercial word-processing programs is within the capability of the 9000E — character search. "Character" may be a single character or a sequence of characters, known in the computer field as a

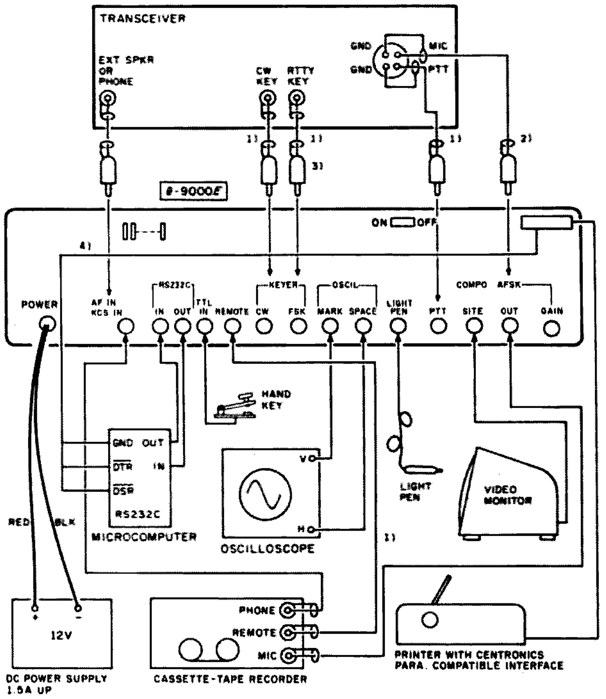

Fig. 1. Peripheral equipment interconnections.

"string." Merely by typing one letter plus the string being sought, the 9000E will search for and display the string upon locating it. This may take a second or two or a fraction of a second depending upon how far the string may be into the text from the start of the search. When found, the screen will scroll to the line where the string is located and the cursor will stop at the beginning of the line that the string is in. If no such string exists, the screen will display "NO DATA." Once found, the string may be deleted, modified, or moved, using the commands for these functions.

A rather unusual function, and one that is not customarily found in many word-processing programs, is the ability to draw vertical and horizontal lines on the screen or printer. A dual keystroke followed by a numeral will draw either one of these from the cursor position to the extent of the numerical quantity that has been entered. The manual describes this operation as the drawing of horizontal/vertical "lines," and the way it is presented is a little confusing. For instance, if nine horizontal "lines" (manual terminology) are to be drawn, nine hyphens in a row will appear. The manual indicates that each hyphen is a "line," which is not really the concept. Of course, you can draw nine truly individual *broken* horizontal lines by requesting the required number of hyphens for each of the nine lines desired. The same applies to vertical "lines." In this case, the vertical "lines" are colons presented vertically down the screen. Regardless of how this is presented in the manual, the ability to draw lines such as these is an excellent way to quickly lay out tables and charts on the screen and the printer.

The 9000E memory may be used for the retention of repetitive material used in the word-processing mode, the lines mentioned above, or names and addresses, etc., for instance, and these may be accessed as required. The memory function will be described in more detail presently in connection with the other functions.

Graphics. The final major function of the 9000E is the graphics mode. This will be mentioned in this review as a major mode, although in the 9000E manual it is relegated to a category of sub-functions that includes split-screen operation and selective calling.

The graphics mode, however, is not only unusual for a communications terminal to have, but also its output may be transmitted to other Theta 9000E terminals and could be useful for rough schematic drawings or block-diagram transmissions.

Graphics are created using a supplied light pen. Once again, for those not too familiar with computer techniques, a light pen may "read" or "write" data to and from a CRT by touching the light-sensitive tip of the pen to the screen. This is exactly what happens with the 9000E, but using the pen to read characters does not apply with this equipment. Any characters created on the screen may be transmitted to either a tape recorder or another Theta as mentioned.

Initially, in the graphics mode, the screen will display a full grid of small light squares (pixels). To use the light pen, the tip is touched against the display, and, while holding one key down, the pen is moved vertically and horizontally, as required. This creates a pattern of small inverted "U" block characters wherever the pen touches a pixel while the key is depressed. When finished, a single command erases all of the remaining pixels, which leaves the sketch as composed.

Memory

The impressive memory capabilities of the 9000E are sufficiently important to warrant review consideration in some detail. Memory in the RTTY mode is like having a built-in paper-tape capability. In this instance, however, you may modify and store data ready for transmission or other use in an instant, and without the noise of a paper punch.

The memory is available for use in all modes. In fact, some data stored in memory may be applicable and used interchangeably in RTTY *and* CW, for instance. But protocol will dictate actual usage: CW abbreviations have limited use, if any, in a RTTY QSO; on the other hand, words spelled out are seldom used in CW, except for traffic handling when this could be particularly useful. (For traffic handling, you can transmit the "received" screen, too.)

A 3120-character buffer memory may be utilized in split-screen mode on the lower portion of the screen. This is a volatile memory. A Random Access Memory (RAM) capability of 256 characters each in seven different channels is also available. Data is maintained in this area with the batteries mentioned under "Hardware." Data in this area may be changed at any time, and in any channel, without disturbing the contents of other channels. It should also be mentioned that data in the buffer may be changed even while being transmitted, if necessary (before it is keyed, of course).

One memory channel (channel 6) has 16 subsections with space for 16 characters each in it, and another (channel 7) has eight subsections of 32 characters each. Transmission of data in the first five channels (256 characters each) may be repeated up to nine times. Channel 6 with its 16 subsections may "chain" or overwrite into a subsequent channel if the number of characters in one exceeds its limits. Thus it, too, may be utilized for 256 characters if necessary. This channel also may be repeated up to nine times.

The operation of channel 7 is similar; however, subsection 7 of this channel has the "QBF" message written in it ("THE QUICK BROWN FOX..."), and "CW ID FOLLOWS" is in subsection 8, which will also normally contain your call. No repeat function occurs in channel 7. A stored "RYRY" is present, too.

Operator's Manual

Until I began reading the manual, I honestly believed that the 9000E was of US manufacture (not yet having looked at the serial-number plate). Almost immediately it was evident that the manual was written in Japanese-oriented English. Not that this pattern is particularly difficult to understand in this instance, but a few of the sentences and phrases throughout the manual are convoluted to the extent that you may ask, "What does this mean?"

In addition, the manual suffers from a lack of good organization, with a number of explanations either redundant or scattered piecemeal in different parts of the manual. A good English editorial treatment of the manual could cut its volume by a third and at the same time make it far more easy to read and understand.

Physically, the manual is composed of 75 pages of sharp typewriter-font copy; it is very legible, being printed on good quality, coated white paper. Sectional numbering is maintained throughout, although there is a preponderance of section, subsection, paragraph, and item numbering, which becomes quite confusing when looking for a particular subject.

All of this is bound in a stiff cardstock blue cover. Unfortunately, the book is glued along the spine, making it impossible to use it open and flat. (I cut the spine off, punched three holes in it, and bound it in a three-ring binder.)

There is a Table of Contents, but no Index, which would be helpful, inasmuch as the breaking up of information as mentioned above may place important information in more than one location.

One section, "Introduction to All the Function Keys," is a valuable inclusion. All keys, used singly, dually, or triply, are shown as they refer to the various functions they perform together with an ex-

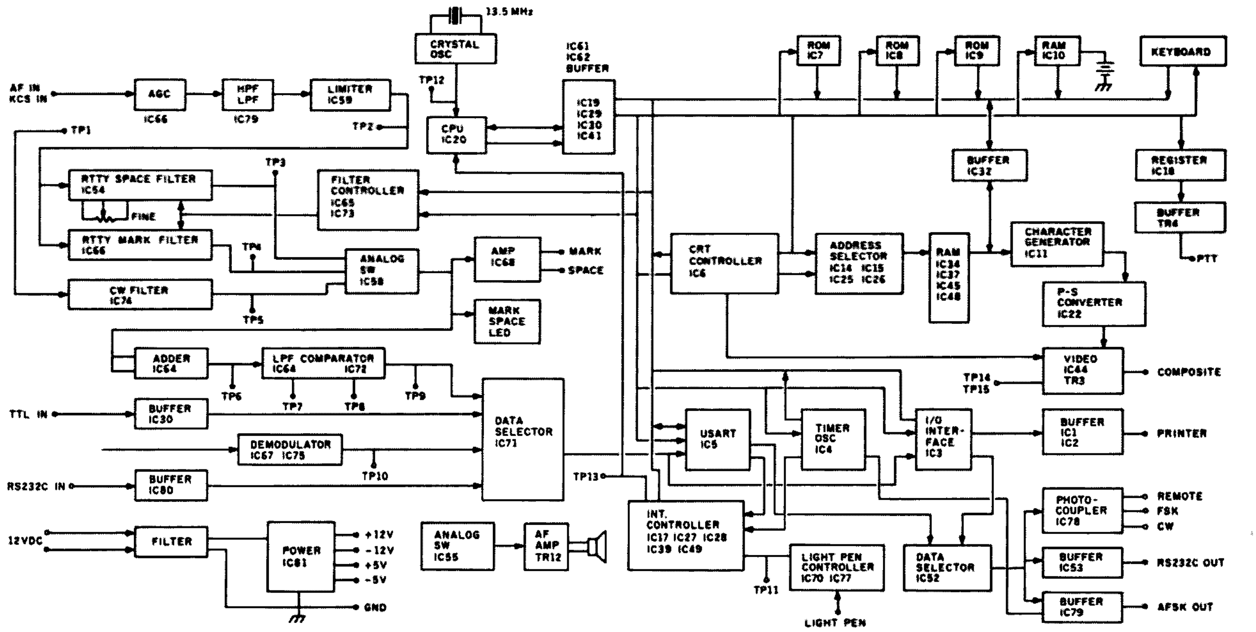

Fig. 2. Drake 9000E block diagram.

planation of exactly what occurs when they are pressed. The keytop identifications, as shown in this section as well as wherever they appear throughout the manual, are uniquely displayed and leave no doubt as to how they are to be used. This lucid system works this way: A keytop drawing is shown as a rectangle. Within it is the letter or word as it appears on the keytop, e.g., "SHIFT." If another key is used immediately afterward as a part of the function, it is shown as well, but with a space between the two. However, if two keys are to be pressed simultaneously, there is no space between the two keytops, just a single line dividing the two rectangles. This is one of the best ways I have seen to describe multi-key operations — and there are many required in computer activities.

There are two photographs in the manual, one of the keyboard (similar to the one shown here, but with callouts) and another of the rear panel of the terminal. Both of these are glossy photographs and were pasted into my copy, which would indicate I received an early copy of the manual (or perhaps that is the way the photos will be provided in all manuals). There are many line drawings explaining how the various screen displays will appear. There is also a good interconnection line drawing, an interconnection drawing for a selcal system, and one for using the 9000E as an RS-232C terminal with an external computer. There are other drawings showing connections to peripheral equipment (printer, recorder, etc.), an input-output circuit drawing, and a block diagram of the entire terminal. There is no schematic, however, and there's a dearth of detailed technical information.

In discussing the latter situation with Drake marketing personnel, I was advised that this was the extent of the information that was available at the present time. This is unfortunate, for although I would probably never attempt to do any serious troubleshooting on this complex unit, I would like to be able to analyze the circuitry. I am sure, too, that prospective owners would like to be able to make specification comparisons. This also raises a question in my mind as to just how Drake proposes to repair these units, under warranty or otherwise, if they have no technical data.

Back to the manual, briefly. Several tables at the back of the manual are useful. One shows the relationship of every key, both in upppercase and lowercase, of each CW, Baudot, and ASCII character and their representation on the monitor screen. Another table shows the CW signal, in dots and dashes, for every applicable key on the terminal. A table of control codes is also included.

Overall, it is a good manual, despite my criticisms. It is amply illustrated, with sometimes more being learned from these line drawings than from the text. Some prior operating experience on the part of the reader is a must in reading it, nevertheless.

Operating the Theta 9000E

Operating the 9000E in any mode is a pleasure. When first turned on, the top line of the video display reads, MODE? You now have a basic choice of selecting any of the available modes of operation simply by pressing one of the dedicated keys. Briefly, here is a typical example of operating supposing you had selected the key labeled MORSE.

Immediately, there is a status display across the lower third of the display. The information provided is MODE (in this instance it will read MODE = CW), TYPE, SENSE, INPUT, PTT, CH = 0, CASE, AUDIO = AGO, CR/LF = OFF, SPEED = 11 WPM, DIDDLE = OFF, and FUNCTION, with each of these indicating the default. It's a wealth of information, and more will be added as you select various functions.

It takes a while to become acquainted with the significant items. I say "significant" because, as the more knowledgeable among the readers will know, all of the function-status items shown above are not required in CW operation. For instance, DIDDLE will be used in RTTY if wanted, but not in CW — that's why it is OFF. The same applies to SENSE. RX = N and TX = N means "Normal," that is, not inverted — another RTTY assignment. It would probably be desirable in the status display if those items not applicable to the mode were not shown.

If you wish, you may now change the screen display from 80 characters of 24 lines to 40 characters of 24 lines, approximately doubling the size of the characters. At the same time, the status display will change to the larger character size and will now require four lines. Whatever is done is purely a matter of preference — many persons have difficulty reading an 80-character screen on a nine-inch monitor, for instance, and will opt for the larger characters. Then, too, some monitors will not accept an 80-character display.

Continuing with this typical CW session, you can now enter information relating to the type of operation to be used. If you will be receiving only, then no further preparation is necessary (assuming your input is audio from the receiver, thus AF in the status line). But if you plan to transmit (or send only to the audio monitor in the terminal) from the keyboard, the default transmitting speed of 11 wpm may need to be changed. One control key followed by one of the numeral keys will provide this change. Key 0 changes the output speed to 5 wpm. The remaining keys move the speed up as 6, 8, 11, 14, 18, 23, 30, 39, and 50 wpm. Also, you can fine-tune the transmitting speed, as has been described before.

The weighting adjustment can be performed within ten limits of 1:3 through 1:6. If you do not wish to enter optional parameters each time you fire up the terminal, you can store them in memory for automatic selection, but of course they may be changed at any time.

You will not change anything for receiving; the 9000E will track CW over the range 5 to 50 wpm. Dots that are less than 20 ms may be regarded as noise. Previous comments regarding the accuracy of the CW for copying apply — there are very few terminals, if any, that will copy rotten CW or what must be termed "non-International Morse." This terminal tends to print what is sent; if it forms a Morse character, it prints; if not, nothing!

Tuning CW is extremely easy. You just tune the receiver on the desired signal until the SPACE LED on the keyboard panel pulses with the signal. At this point, the audio signal is passing through the bandpass filter, which has a center frequency of 830 Hz. Tuning may also be done using the audio-monitor output, but this entails an extra keystroke to set up.

When you are ready to transmit, you may do so by applying whatever system your station requires to do so manually or by merely depressing the PTT key (yes, even on CW or RTTY, Push to Talk). When this is done, depressing any key will immediately start transmission. Pressing a two-key combination returns you to receive.

In CW, standard prosigns operate both in transmit and receive. Barred KN, AR, AS, and VA are available, for instance, and punctuation symbols such as colon, hyphen, right and left parentheses, etc., transmit the International Morse signals for these characters or print their deciphered representation. Barred BT is represented as " = " and barred AR as the " + " symbol, for example.

Initializing in either Baudot or ASCII RTTY mode is the same as for CW but by pressing the appropriate single keys for these modes. When the status display comes up, you enter whatever parameters you will be operating. The default in Baudot will be low-frequency tones, 170-Hz shift, and 45.45-baud operation. Any selection made will apply to both AFSK and FSK operation, which will have been chosen beforehand. As shown in the specifications, the 9000E accommodates both low and high tones. The protocol in ham operation is that the low-frequency shifts are used for HF operation and the high-frequency shifts (e.g., 2125 and 2295 Hz for a 170-Hz shift) are used in VHF operation.

You can change the default to a shift of 425 Hz or 850 Hz in both low- and high-tone groups. If 170 Hz in high-tone shift is needed, then this too must be entered as it is not the default. There is one other shift for KCS, which has mark at 2400 Hz and space at 1200 Hz. This is set from the ASCII mode.

In addition to the many sub-functions that have been mentioned before, you also have several other options designed for RTTY operation: ANTI, which will bring in anti-noise filtering and thus prevent garbage from printing; the optimum line length before carriage return (80, 72, or 84 characters, not to be confused with screen character width); and defeat of the carriage return. The latter action would be desirable if you were transmitting or re-

ceiving RTTY pictures, for instance. Speeds will also be set at this time, keeping in mind the previous comments about approved speeds. (It is extremely interesting to watch a stream of data displaying at 9600 baud, but don't try this on the air if you are operating lower than 50.0 MHz!)

DIDDLE (sometimes called IDLE) has a default of OFF and the function is not too often heard on the ham bands. This is a Letters code continuously transmitted whenever a printing character is not being transmitted, indicating the frequency is being used and the RTTY signal is not just a carrier (slower typists appear to use it to some extent). USO (Unshift on Space) can also be programmed, but this is not a function that can be placed into memory. Its use, too, is infrequent, but it is of great assistance when receiving weak signals. This places the terminal back into Letters case upon receipt of a space signal, thus preventing the printer or display from hanging up in Figures case for more than a few characters. Associated with this, the CASE = statement on the status display will show at all times the Letters or Figures status being received or transmitted at the moment it is occurring, except in ASCII mode. In the latter operation, ASCII will normally be operating as a typewriter would: in lowercase except for capitals and punctuation, with numerals transmitted as lowercase characters. (This does not preclude operating with all capitals in ASCII, however.)

Operation in RTTY is essentially the same as for CW. Depressing one key puts you on the air (or to tape, screen, or printer). You may operate one-on-one so to speak, whereby as soon as you stop transmitting and sign over, you are back to receiving; incidentally, there is not too much dialog-type operation (semi break-in) going on on the ham bands with RTTY. This is unfortunate, because the 9000E is ideally suited for this. As it is, most of the operation we see is of the type whereby one station transmits a long monolog and then waits for the same from the other station. If this is your style, the 9000E is perfectly compatible for this, too.

Splitting the screen facilitates this technique. A keystroke places all received data in the top nine lines of the screen. The transmitting screen is eight lines below this, with a blank line between. Following another blank line, the status display appears (two lines in 80-character mode) and remains always visible. Below the status display, there are three lines reserved for buffer memory. With this arrangement, while the other station is sending CQ, for example, you can be typing your call into the buffer and entering the automatic CW ID FOLLOWS command. As soon as the station signs, pressing just two keys transmits your buffer data. As it dumps out of the buffer, it will disappear off to the left of the screen, letter by letter, to reappear in the transmitting area of the screen as it is transmitted. You now have a record of the receiving and transmitting screens if you are making hard copy at the same time.

Nothing could be easier, and there is a great advantage in being able to compose your replies while the other station transmits, with your transmission streaming out at the full speed at which you are operating. Until the buffer is emptied, no one will know that you can type only five words per minute. Most operators will probably be able to keep up with the buffer at 60 wpm, especially if they have a few lines started before the other station signs over. Higher speeds will tax the skill of even the fastest operator.

CW operation can be just as much fun, with the restriction already noted about good CW being needed. No problems were noted in 100% copy at 35 wpm from W1AW taped bulletins and a number of commercial press stations at speeds of 20 to 40 wpm.

Selective Calling (Selcal)

Selcal can be used in any mode for receiving and transmitting and is one of the easiest to prepare for operation with this terminal.

Your identifying characters are stored in one of the memory channels prior to operation, and selcal is left activated. Upon receiving the same characters as stored in memory, the data being sent will be stored in a memory block and printed or displayed if activated. It may also be printed later, of course.

If you have stored data waiting for transmission, receipt of your END OF TEXT data, also previously prepared, will automatically transmit your data from memory. Although most applications of selcal operation will be in RTTY operation, as noted above it may be used in any mode, which includes CW.

Receiving Commercial Stations

No difficulty whatsoever was experienced in receiving any RTTY appearing on the ham bands where everyone generally was using 170-Hz shift and 60, 75, and 100 wpm. ASCII is being used to some extent, but it is necessary that its characteristics be recognized in order to place the terminal in ASCII mode for reception, even though you can switch from Baudot to ASCII at the touch of a key.

Tuning commercial RTTY stations required considerable patience in most cases. This is due to the fact that although a multitude of stations are scattered throughout the HF and LF spectrum, they are using odd frequency shifts, inverted signals, and numerous transmission speeds, so that it becomes a problem to immediately decipher the mode, speed, etc. Some will never be attainable and others, even when they are copied, are of little interest unless you are into cryptography.

There are tuning aids on the 9000E that make it easier to copy such stations, though. By carefully tuning so that you obtain both mark and space indications on the LEDs on the panel and then using the fine-tuning control, it is possible to establish the shift width. Of course, this may mean going through the operation for 170-, 425-, and 850-Hz positions. You may then need to determine the speed of transmission to have copy appear on the display. And in each situation you may need to determine whether or not the signal is inverted.

All things considered, tuning commercial stations can be a challenge. A good commercial station list such as published by Universal Electronics, Inc., in Reynoldsburg, Ohio, is invaluable in locating and tuning these stations. These guides give the transmission frequency, shift, speed, inversion, and type of transmission for hundreds of stations.

Problems and Criticisms

There was one unexplained action that occurred under certain circumstances but which cannot properly be considered a problem. This was when an attempt was made to perform a function that the terminal was not programmed to do at the moment. For instance, when a tone shift was attempted but a non-applicable secondary key was pressed, the speaker in the audio monitor chirped briefly. This could be some sort of alerting signal, but if it was, it was not mentioned in the manual. The R. L. Drake Company had no explanation for this either, except to agree that it might be a warning signal.

One other possible problem that appeared to be originating in the terminal was a slight non-linearity in the display about mid-screen. This gave the effect of sloping letters on a line. This occurred with three different monitors and could be a voltage-regulation problem. This corrected itself after about ten minutes of operation.

The connectors that were described earlier could eventually cause intermittent contact problems. The use of BNC-type connectors would probably increase the end-user cost by about ten dollars, but this would be in keeping with the other professional aspects of this terminal.

When the 9000E was connected to a Yaesu FRG-7700 receiver which used a wire antenna directly to the antenna terminal, the RFI from the 9000E microprocessor completely obliterated all signal reception — this notwithstanding statements of minimal radiation problems. Connecting the receiver via coaxial cable to another antenna (vertical) located 40 feet away from the terminal eliminated any vestige of RFI.
